

- High-Performance Static CMOS Technology
- Includes the '320C2xLP Core CPU
- TMS320C206, TMS320LC206 are Members of the 'C20x/'C2000 Platform Which Also Includes the TMS320C203/LC203 and TMS320F206 Devices
- Instruction-Cycle Time 25 ns at 3.3 V
- Source Code Compatible With TMS320C25 and other '20x Devices
- Upwardly Code-Compatible With TMS320C5x Devices
- Four External Interrupts
- TMS320C206, 5-V I/O (3.3-V core)
- TMS320LC206, 3.3-V core and I/O
- TMS320C206, TMS320LC206 Integrated Memory:
 - 544 × 16 Words of On-Chip Dual-Access Data RAM
 - 32K × 16 Words of On-Chip ROM
 - 4K × 16 Words of On-Chip Single-Access Program/Data RAM
- 224K × 16-Bit Maximum Addressable External Memory Space
 - 64K Program
 - 64K Data
 - 64K Input/Output (I/O)
 - 32K Global
- 32-Bit Arithmetic Logic Unit (ALU) Accumulator
- 16 × 16-Bit Multiplier With a 32-Bit Product
- Block Moves from Data and Program Space
- TMS320C206, TMS320LC206 Peripherals:
 - On-Chip 20-Bit Timer
 - On-Chip Software-Programmable Wait-State (0 to 7) Generator
 - On-Chip Oscillator
 - On-Chip Phase-Locked Loop (PLL)
 - Six General-Purpose I/O Pins
 - Full-Duplex Asynchronous Serial Port (UART)
 - Enhanced Synchronous Serial Port (ESSP) With Four-Level-Deep FIFOs
- Input Clock Options
 - Options: Multiply-by-One, -Two, or -Four, and Divide-by-Two (×1, ×2, ×4, and ÷2)
- Support of Hardware Wait States
- Power Down IDLE Mode
- IEEE 1149.1†-Compatible Scan-Based Emulation
- TMS320C206, TMS320LC206 100-Pin PZ Package, Small Thin Quad Flat Package (TQFP)
- Industrial Temperature Version Planned, (– 40°C to 85°C)

description

The Texas Instruments (TI™) TMS320C206‡ and TMS320LC206‡ digital signal processors (DSPs) are fabricated with static CMOS integrated-circuit technology. The architectural design is based upon that of the TMS320C20x series and is optimized for low-power operation. The combination of advanced Harvard architecture, on-chip peripherals, on-chip memory, and a highly specialized instruction set is the basis of the operational flexibility and speed of the 'C206.

The 'C206 offers these advantages:

- Enhanced TMS320 architectural design for increased performance and versatility
- Advanced integrated-circuit processing technology for increased performance
- 'C206 devices are pin- and code-compatible with 'C203 and 'F206 devices.
- Source code for the 'C206 DSPs is software-compatible with the 'C1x and 'C2x DSPs and is upwardly compatible with fifth-generation DSPs ('C5x)
- New static-design techniques for minimizing power consumption and increasing radiation tolerance

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

† IEEE Standard 1149.1-1990, IEEE Standard Test-Access Port

‡ Device numbers are hereafter referred to in the data sheet as 'C206, unless otherwise specified.

TI is a trademark of Texas Instruments Incorporated.

PRODUCTION DATA information is current as of publication date. Products conform to specifications per the terms of Texas Instruments standard warranty. Production processing does not necessarily include testing of all parameters.

DIGITAL SIGNAL PROCESSORS

SPRS065B – JUNE 1998 – REVISED JANUARY 1999

device features

Table 1 shows the capacity of on-chip RAM and ROM, the number of serial and parallel I/O ports, the execution time of one machine cycle, and the type of package with total pin count of the TMS320C206 and TMS320LC206 devices.

Table 1. Characteristics of the TMS320C206 and TMS320LC206 Processors

'x206 DEVICES	ON-CHIP MEMORY (16-BIT WORDS)				I/O PORTS		POWER SUPPLY (V)	CYCLE TIME (ns)	PACKAGE TYPE WITH PIN COUNT
	RAM		ROM	FLASH EEPROM					
	DATA	DATA/ PROG	PROG	PROG	SERIAL	PARALLEL			
TMS320C206	288 [†]	4K + 256 [‡]	32K	–	2	64K	5 (3.3 core)	25	100-pin TQFP
TMS320LC206	288 [†]	4K + 256 [‡]	32K	–	2	64K	3.3	25	100-pin TQFP

[†] On-chip RAM space B1 (256 words) and B2 (32 words) can be used as data memory only.

[‡] On-chip RAM space B0 (256 words) can be used either in data space or program space depending on the value of the CNF bit in the ST1 register.
On-chip SARAM (4K) can be mapped in program space, data space, or both.

SPRS065B – JUNE 1998 – REVISED JANUARY 1999

TMS320C206, TMS320LC206 Terminal Functions

TERMINAL NAME	NO.	TYPE†	DESCRIPTION
DATA AND ADDRESS BUSES			
D15 D14 D13 D12 D11 D10 D9 D8 D7 D6 D5 D4 D3 D2 D1 D0	41 40 39 38 36 34 33 32 31 29 28 27 26 24 23 22	I/O/Z	Parallel data bus D15 [most significant bit (MSB)] through D0 [least significant bit (LSB)]. D15–D0 are used to transfer data between the 'C206 devices and external data/program memory or I/O devices. Placed in the high-impedance state when not outputting (\overline{RD} , \overline{WE} high) or when \overline{RS} asserted. They also go into the high-impedance state when \overline{OFF} is active low.
A15 A14 A13 A12 A11 A10 A9 A8 A7 A6 A5 A4 A3 A2 A1 A0	74 73 72 71 69 68 67 66 64 62 61 60 58 57 56 55	O/Z	Parallel address bus A15 (MSB) through A0 (LSB). A15–A0 are used to address external data/program memory or I/O devices. These signals go into the high-impedance state when \overline{OFF} is active low.
MEMORY CONTROL SIGNALS			
\overline{PS}	53	O/Z	Program-select. \overline{PS} is always high unless low-level asserted for communicating to off-chip program space. \overline{PS} goes into the high-impedance state when \overline{OFF} is active low.
\overline{DS}	51	O/Z	Data-select. \overline{DS} is always high unless low-level asserted for communicating to off-chip data space. \overline{DS} goes into the high-impedance state when \overline{OFF} is active low.
\overline{IS}	52	O/Z	I/O space select. \overline{IS} is always high unless low-level asserted for communicating to I/O ports. \overline{IS} goes into the high-impedance state when \overline{OFF} is active low.
READY	49	I	Data-ready. READY indicates that an external device is prepared for the bus transaction to be completed. If the external device is not ready (the external device pulls READY low), the 'C206 waits one cycle and checks READY again. If READY is not used, it should be pulled high.
R/\overline{W}	47	O/Z	Read/write. R/\overline{W} indicates data transfer direction when communicating with an external device. R/\overline{W} is normally in read mode (high), unless low level is asserted for performing a write operation. R/\overline{W} goes into the high-impedance state when \overline{OFF} is active low.

† I = input, O = output, Z = high impedance, PWR = power, GND = ground

POST OFFICE BOX 1443 • HOUSTON, TEXAS 77251-1443

TMS320C206, TMS320LC206 Terminal Functions (Continued)

TERMINAL NAME	NO.	TYPE†	DESCRIPTION
MEMORY CONTROL SIGNALS (CONTINUED)			
$\overline{\text{RD}}$	45	O/Z	Read-select indicates an active, external read cycle. $\overline{\text{RD}}$ is active on all external program, data, and I/O reads. $\overline{\text{RD}}$ goes into the high-impedance state when $\overline{\text{OFF}}$ is active low. To implement a glueless zero wait-state memory interface, the inverted $\text{R}/\overline{\text{W}}$ signal can be used as the "read" signal in place of $\overline{\text{RD}}$. The function of the $\overline{\text{RD}}$ pin can be programmed to provide an inverted $\text{R}/\overline{\text{W}}$ signal instead of $\overline{\text{RD}}$. The FRDN bit (bit 15) in the PMST register controls this selection. FRDN=1 chooses $\text{R}/\overline{\text{W}}$ as the new "read" signal. FRDN=0 (at reset) chooses $\overline{\text{RD}}$ as the "read" signal on pin 45.
$\overline{\text{WE}}$	44	O/Z	Write enable. The falling edge of $\overline{\text{WE}}$ indicates that the device is driving the external data bus (D15–D0). Data can be latched by an external device on the rising edge of $\overline{\text{WE}}$. $\overline{\text{WE}}$ is active on all external program, data, and I/O writes. $\overline{\text{WE}}$ goes into the high-impedance state when $\overline{\text{OFF}}$ is active low.
$\overline{\text{STRB}}$	46	O/Z	Strobe. $\overline{\text{STRB}}$ is always high unless asserted low to indicate an external bus cycle. $\overline{\text{STRB}}$ goes into the high-impedance state when $\overline{\text{OFF}}$ is active low.
MULTI-PROCESSING SIGNALS			
$\overline{\text{BR}}$	43	O/Z	Bus-request. $\overline{\text{BR}}$ is asserted when a global data-memory access is initiated. $\overline{\text{BR}}$ goes into the high-impedance state when $\overline{\text{OFF}}$ is active low.
$\overline{\text{HOLDA}}$	6	O/Z	Hold-acknowledge. $\overline{\text{HOLDA}}$ indicates to the external circuitry that the processor is in a hold state and that the address, data, and memory control lines are in the high-impedance state so that they are available to the external circuitry for access of local memory. $\overline{\text{HOLDA}}$ goes into the high-impedance state when $\overline{\text{OFF}}$ is active low.
XF	98	O/Z	External flag output (latched software-programmable signal). XF is used for signalling other processors in multiprocessing configurations or as a general-purpose output pin. XF goes into the high-impedance state when $\overline{\text{OFF}}$ is active low.
$\overline{\text{BIO}}$	99	I	Branch control input. When polled by the BCND pma, BIO instruction, 'C206 executes a branch to the specified program memory address if $\overline{\text{BIO}}$ is low.
IO0 IO1 IO2 IO3	96 97 8 9	I/O/Z	Software-controlled input/output by way of the asynchronous serial-port control register (ASPCR). At reset, IO0–IO3 are configured as inputs. These pins can be used as general-purpose input/output pins or as handshake control for the UART. IO0–IO3 go into the high-impedance state when $\overline{\text{OFF}}$ is active low.
INITIALIZATION, INTERRUPTS, AND RESET OPERATIONS			
$\overline{\text{RS}}$	100	I	Reset. $\overline{\text{RS}}$ causes the 'C206 and 'LC206 to terminate execution and forces the program counter to zero. When $\overline{\text{RS}}$ is brought high, execution begins at location 0 of program memory after 16 cycles. $\overline{\text{RS}}$ affects various registers and status bits.
$\overline{\text{PLLRS}}$	10	I	Phase locked loop reset. $\overline{\text{PLLRS}}$ resets the PLL to initiate PLL locking. At power up, both $\overline{\text{PLLRS}}$ and $\overline{\text{RS}}$ should be active (low) to reset the DSP core and the PLL circuitry. The PLL can only be reset along with the core as shown in Table 2. The state of the $\overline{\text{PLLRS}}$ is not applicable for $\div 2$ mode and should always be tied high or low.
EXT8	1	I	Bootloader mode pin. EXT8 is latched to bit 3 (LEVEXT8) in the PMST register. The bootloader located in ROM uses EXT8 to determine the type of boot method. If EXT8 is high, the enhanced 'C206 bootloader is used. If EXT8 is low, the 'C203 style bootloader is used. Refer to the <i>TMS320C20x User's Guide</i> (literature number SPRU127) for more details regarding the 'C203 style bootloader.
$\text{MP}/\overline{\text{MC}}$	2	I	Microprocessor/microcomputer mode select. If $\text{MP}/\overline{\text{MC}}$ is low, the on-chip ROM memory is mapped into program space. When $\text{MP}/\overline{\text{MC}}$ is high, the device accesses off-chip memory. This pin is only sampled at RESET, and its value is latched into bit 0 of the PMST register.
$\overline{\text{NMI}}$	17	I	Nonmaskable interrupt. $\overline{\text{NMI}}$ is an external interrupt that cannot be masked by way of the interrupt-mode bit (INTM) or the interrupt-mask register (IMR). When $\overline{\text{NMI}}$ is activated, the processor traps to the appropriate vector location. If $\overline{\text{NMI}}$ is not used, it should be pulled high.
$\overline{\text{HOLD}}/\overline{\text{INT1}}$	18	I	$\overline{\text{HOLD}}$ and $\overline{\text{INT1}}$ share the same pin. Both are treated as interrupt signals. If the MODE bit is 0 in the interrupt control register (ICR), hold logic can be implemented in combination with the IDLE instruction in software. At reset, the MODE bit in ICR is zero, enabling the HOLD mode for the pin.
$\overline{\text{INT2}}$ $\overline{\text{INT3}}$	19 20	I	External user interrupts. $\overline{\text{INT2}}$ and $\overline{\text{INT3}}$ are prioritized and maskable by the IMR and the INTM. $\overline{\text{INT2}}$ and $\overline{\text{INT3}}$ can be polled and reset by way of the interrupt flag register (IFR).

† I = input, O = output, Z = high impedance, PWR = power, GND = ground

TMS320C206, TMS320LC206 DIGITAL SIGNAL PROCESSORS

SPRS065B – JUNE 1998 – REVISED JANUARY 1999

TMS320C206, TMS320LC206 Terminal Functions (Continued)

TERMINAL NAME	NO.	TYPE†	DESCRIPTION
OSCILLATOR, PLL, AND TIMER SIGNALS			
TOUT	92	O	Timer output. TOUT signals a pulse when the on-chip timer counts down past zero. The pulse is one CLKOUT1 cycle wide. TOUT goes into the high-impedance state when $\overline{\text{OFF}}$ is active low.
CLKOUT1	15	O/Z	Master clock output. The CLKOUT1 high pulse signifies the logic phase while the low pulse signifies the latch phase.
CLKIN/X2 X1	12 13	I O	Input clock. CLKIN/X2 is the input clock to the device. As CLKIN, the pin operates as the external oscillator clock input and as X2, the pin operates as the internal oscillator input with X1 being the internal oscillator output.
DIV1 DIV2	3 5	I	DIV1 and DIV2 are used to configure the on-chip PLL options, providing four clock modes ($\times 2$, $\times 1$, $\times 2$, and $\times 4$) for a given input clock frequency. Refer to clock options in electrical characteristics section. Note that in the divide-by-2 mode, the PLL is bypassed. DIV1 – DIV2 should not be changed unless the $\overline{\text{RS}}$ signal is active.
SERIAL PORT SIGNALS (SSP AND ASP)			
CLKX	87	I/O	Transmit clock. CLKX is a clock signal for clocking data from the XSR (transmit shift register) to the DX data-transmit pin. CLKX can be an input if the MCM bit in the synchronous serial-port control register (SSPCR) is set to 0. CLKX can also be driven by the device at one-half of the CLKOUT1 frequency when MCM = 1. If the serial port is not being used, CLKX goes into the high-impedance state when $\overline{\text{OFF}}$ is active low. Value at reset is as an input.
CLKR	84	I	Receive clock. External clock signal for clocking data from the DR (data-receive) pin into the serial-port receive shift register (RSR). CLKR must be present during serial-port transfers. If the serial port is not being used, CLKR can be sampled as an input by IN0 bit of the SSPCR.
FSX	89	I/O	Frame synchronization pulse for transmit. The falling edge of the FSX pulse initiates the data-transmit process, beginning the clocking of the SR. Following reset, FSX is an input. FSX can be selected by software to be an output when the TXM bit in the serial control register, SSPCR, is set to 1. FSX goes into the high-impedance state when $\overline{\text{OFF}}$ is active low.
FSR	85	I	Frame synchronization pulse for receive input. The falling edge of the FSR pulse initiates the data-receive process, beginning the clocking of the RSR. FSR goes into the high-impedance state when $\overline{\text{OFF}}$ is active low.
DX	90	O	Synchronous serial port (SSP) data transmit output. Serial data is transmitted from the transmit shift register (XSR) through the DX pin. DX is in the high-impedance state when $\overline{\text{OFF}}$ is active low.
DR	86	I	Synchronous serial port (SSP) data receive input. Serial data is received in the receive shift register (RSR) through the DR pin.
TX	93	O	Asynchronous serial port (ASP/UART) data transmit output pin
RX	95	I	Asynchronous serial port (ASP/UART) data receive pin
TEST SIGNALS			
$\overline{\text{TRST}}$	79	I	IEEE Standard 1149.1 (JTAG) test reset. $\overline{\text{TRST}}$, when active high, gives the scan system control of the operations of the device. If $\overline{\text{TRST}}$ is driven low, the device operates in its functional mode, and the test signals are ignored. If the $\overline{\text{TRST}}$ pin is not driven, an external pulldown resistor must be used.
TCK	78	I	JTAG test clock. TCK is normally a free-running clock signal with a 50% duty cycle. The changes on the test-access port (TAP) input signals (TMS and TDI) are clocked into the TAP controller, instruction register, or selected test-data register on the rising edge of TCK. Changes at the TAP output signal (TDO) occur on the falling edge of TCK.
TMS	81	I	JTAG test-mode select. TMS is clocked into the TAP controller on the rising edge of TCK.
TDI	80	I	JTAG test-data input. TDI is clocked into the selected register (instruction or data) on a rising edge of TCK.
TDO	82	O/Z	JTAG test-data output. The contents of the selected register (instruction or data) are shifted out of TDO on the falling edge of TCK. TDO is in the high-impedance state except when the scanning of data is in progress.
EMU0	76	I/O/Z	Emulator pin 0. When $\overline{\text{TRST}}$ is driven low, EMU0 must be high for activation of the $\overline{\text{OFF}}$ condition. When $\overline{\text{TRST}}$ is driven high, EMU0 is used as an interrupt to or from the emulator system and is defined as an input/output through the JTAG scan.

† I = input, O = output, Z = high impedance, PWR = power, GND = ground

TMS320C206, TMS320LC206 Terminal Functions (Continued)

TERMINAL NAME	NO.	TYPE†	DESCRIPTION
TEST SIGNALS (CONTINUED)			
EMU1/ $\overline{\text{OFF}}$	77	I/O/Z	Emulator pin 1. Emulator pin 1 disables all outputs. When $\overline{\text{TRST}}$ is driven high, EMU1/ $\overline{\text{OFF}}$ is used as an interrupt to or from the emulator system and is defined as an input/output through the JTAG scan. When $\overline{\text{TRST}}$ is driven low, this pin is configured as $\overline{\text{OFF}}$. EMU1/ $\overline{\text{OFF}}$, when active low, puts all output drivers in the high-impedance state. Note that $\overline{\text{OFF}}$ is used exclusively for testing and emulation purposes (not for multiprocessing applications). Therefore, for the $\overline{\text{OFF}}$ condition, the following apply: $\overline{\text{TRST}} = 0$ $\text{EMU0} = 1$ $\text{EMU1}/\overline{\text{OFF}} = 0$
SUPPLY PINS			
V_{DD5}	7 16 35 50 63 91	PWR	5-V I/O power supply (Applicable for TMS320C206 only‡)
V_{DD}	7 16 35 50 63 91	PWR	3.3-V I/O power supply (Applicable for 'LC206 only)
V_{DD}	4 11 75	PWR	3.3-V core power supply (Applicable for both 'C206 and 'LC206 devices‡)
V_{SS}	14 21 25 30 37 42 48 54 59 65 70 83 88 94	GND	Ground

† I = input, O = output, Z = high impedance, PWR = power, GND = ground

‡ For the 'C206, the 3.3-V and 5-V power supplies may be sequenced in any order.

Table 2. Resetting the DSP Core and PLL Circuitry

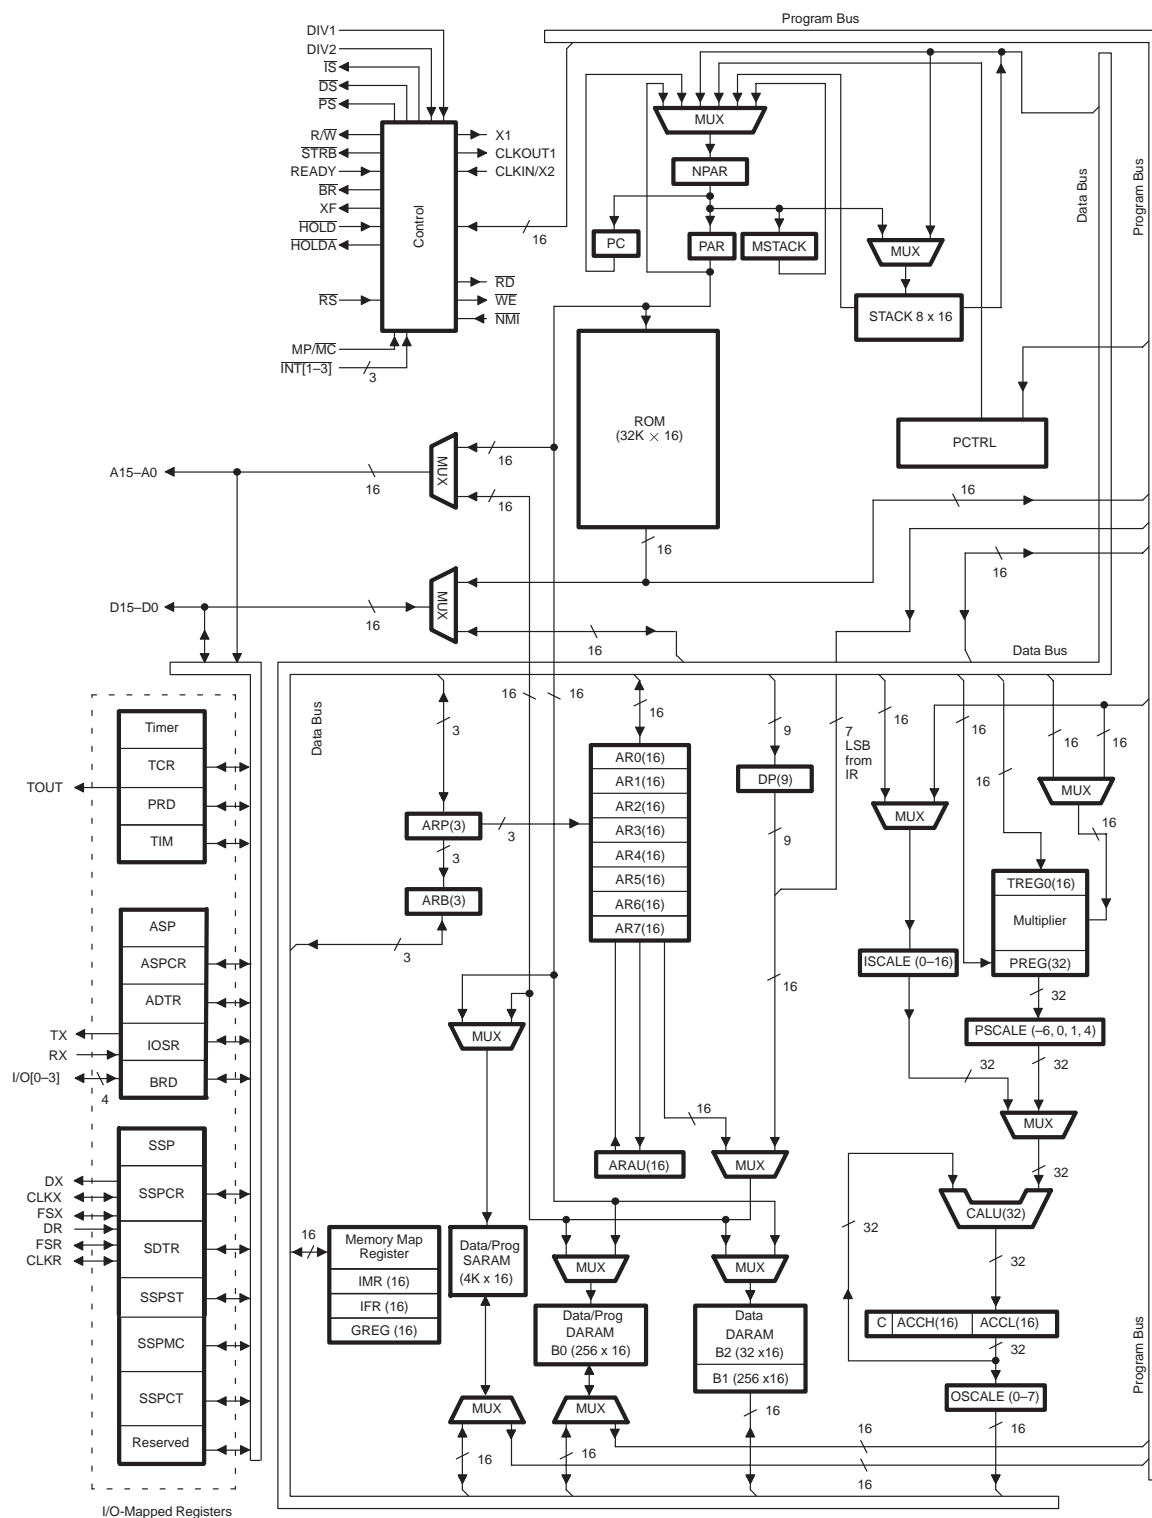

RS	PLLRS	CORE STATUS	PLL STATUS
0	0	Reset	Reset
0	1	Reset	Normal Operation
1	0	Normal Operation	Normal Operation§
1	1	Normal Operation	Normal Operation

§ The PLL can only be reset along with the DSP core and peripherals.

SPRS065B – JUNE 1998 – REVISED JANUARY 1999

functional block diagram of the 'C206 internal hardware

NOTES: A. Symbol descriptions appear in Table 3 and Table 4.

B. For clarity, the data and program buses are shown as single buses although they include address and data bits.

POST OFFICE BOX 1443 • HOUSTON, TEXAS 77251-1443

Table 3. Legend for the 'C206 Internal Hardware Functional Block Diagram

SYMBOL	NAME	DESCRIPTION
ACC	Accumulator	32-bit register that stores the results and provides input for subsequent CALU operations. Also includes shift and rotate capabilities. ACCH is the accumulator high word; ACCL is the accumulator low word.
ADTR	Asynchronous Data Transmit and Receive Register	16-bit read/write register used to transmit data from/receive data into the asynchronous serial port. Note that the ASP works with 8-bit data.
ARAU	Auxiliary Register Arithmetic Unit	An unsigned, 16-bit arithmetic unit used to calculate indirect addresses using the auxiliary registers as inputs and outputs.
ARB	Auxiliary Register Pointer Buffer	See Table 4 for status register field definitions.
ARP	Auxiliary Register Pointer	See Table 4 for status register field definitions.
ASP	Universal Asynchronous Receive/Transmit	ASP is the asynchronous serial port (UART).
ASPCR	Asynchronous Serial-Port Control Register	ASPCR controls the asynchronous serial-port operation. This register contains bits for setting port modes, enabling/disabling automatic baud-rate detection, selecting the number of stop bits, and configuring I/O pins, etc.
AUX REGS (AR0–AR7)	Auxiliary Registers 0–7	These 16-bit registers are used as pointers to anywhere within the data space address range. They are operated upon by the ARAU and are selected by the auxiliary register pointer (ARP). AR0 can also be used as an index value for AR updates of more than one and as a compare value to AR.
$\overline{\text{BR}}$	Bus Request Signal	$\overline{\text{BR}}$ is asserted during access of the external global data memory space. $\overline{\text{READY}}$ is asserted to the device when the global data memory is available for the bus transaction. $\overline{\text{BR}}$ can be used to extend the data memory address space by up to 32K words.
BRD	Baud-Rate Divisor	Used to set the baud rate of the UART.
C	Carry	Register carry output from CALU. C is fed back into the CALU for extended arithmetic operation. The C bit resides in status register 1 (ST1), and can be tested in conditional instructions. C is also used in accumulator shifts and rotates.
CALU	Central Arithmetic Logic Unit	32-bit-wide main arithmetic logic unit for the TMS320C20x core. The CALU executes 32-bit operations in a single machine cycle. CALU operates on data coming from ISCALE or PSCALE with data from ACC, and provides status results to PCTRL.
DARAM	Dual Access RAM	If the on-chip RAM configuration control bit (CNF) is set to 0, the reconfigurable dual-access RAM (DARAM) block B0 is mapped to data space; otherwise, B0 is mapped to program space. Blocks B1 and B2 are mapped to data memory space only, at addresses 0300–03FF and 0060–007F, respectively. Blocks 0 and 1 contain 256 words, while Block 2 contains 32 words.
DP	Data Memory Page Pointer	See Table 4 for status register field definitions.
GREG	Global Memory Allocation Register	GREG specifies the size of the global data memory space.
IFR	Interrupt Flag Register	The 7-bit IFR indicates that the 'C206 has latched an interrupt pulse from one of the seven maskable interrupt sources.
IMR	Interrupt Mask Register	IMR individually masks or enables the seven interrupts.
INT#	Interrupt Traps	A total of 32 interrupts by way of hardware and/or software are available.
IOSR	I/O Status Register	IOSR detects current levels (and changes with inputs) on pins IO0–IO3 and the status of UART.
IR	Instruction Register	IR is the instruction register.

TMS320C206, TMS320LC206 DIGITAL SIGNAL PROCESSORS

SPRS065B – JUNE 1998 – REVISED JANUARY 1999

Table 3. Legend for the 'C206 Internal Hardware Functional Block Diagram (Continued)

SYMBOL	NAME	DESCRIPTION
ISCALE	Input Data-Scaling Shifter	16-bit to 32-bit barrel left-shifter. ISCALE (ISFL) shifts incoming 16-bit data 0 to 16 positions left, relative to the 32-bit output within the fetch cycle; therefore, no cycle overhead is required for input scaling operations.
MPY	Multiplier	16 × 16-bit multiplier to a 32-bit product. MPY executes multiplication in a single cycle. MPY operates either signed or unsigned 2s-complement arithmetic multiply.
MSTACK	Micro Stack	MSTACK provides temporary storage for the address of the next instruction to be fetched when program-address-generation logic is used to generate sequential addresses in data space.
MUX	Multiplexer	Multiplexes buses to a common input
NPAR	Next Program Address Register	NPAR holds the program address to be driven out on the PAB on the next cycle.
OSCALE	Output Data-Scaling Shifter	32-bit to 16-bit barrel left-shifter. OSCALE (OSFL) shifts the 32-bit accumulator output 0 to 7 bits left for quantization management and outputs either the 16-bit high- or low-half of the shifted 32-bit data to the Data-Write Data Bus (DWEB).
PAR	Program Address Register	PAR holds the address currently being driven on PAB for as many cycles as it takes to complete all memory operations scheduled for the current bus cycle.
PC	Program Counter	PC increments the value from NPAR to provide sequential addresses for instruction-fetching and sequential data-transfer operations.
PCTRL	Program Controller	PCTRL decodes instruction, manages the pipeline, stores status, and decodes conditional operations.
PRD	Timer-Period Register	PRD contains the 16-bit period that is loaded into the timer counter when the counter borrows or when the reload bit is activated. Reset initializes the PRD to FFFFh.
PREG	Product Register	32-bit register holds results of 16 × 16 multiply.
PSCALE	Product-Scaling Shifter	0-, 1- or 4-bit left shift or 6-bit right shift of multiplier product. The left-shift options are used to manage the additional sign bits resulting from the 2s-complement multiply. The right-shift option is used to scale down the number to manage overflow of product accumulation in the CALU. PSCALE (PSFL) resides in the path from the 32-bit product shifter and from either the CALU or the DWEB, and requires no cycle overhead.
SDTR	Synchronous Data Transmit and Receive Register	16-bit read/write register used to transmit data from/receive data into the synchronous serial port. This register functions as the path to the transmit and receive FIFOs of the SSP.
SSP	Synchronous Serial-Port	SSP is the synchronous serial-port.
SSPCR	Synchronous Serial-Port Control Register	SSPCR is the control register for selecting the serial port's mode of operation.
SSPCT	Synchronous Serial-Port Counter Register	SSPCT is the synchronous serial-port counter register.
SSPMC	Synchronous Serial-Port Multichannel Register	SSPMC is the synchronous serial-port multichannel register.
SSPST	Synchronous Serial-Port Status Register	SSPST is the synchronous serial-port status register.
STACK	Stack	STACK is a block of memory used for storing return addresses for subroutines and interrupt-service routines, or for storing data. The 'C20x stack is 16-bit wide and eight-level deep.
TCR	Timer-Control Register	TCR contains the control bits that define the divide-down ratio, start/stop the timer, and reload the period. Also contained in TCR is the current count in the prescaler. Reset initializes the timer divide-down ratio to 0 and starts the timer.

Table 3. Legend for the 'C206 Internal Hardware Functional Block Diagram (Continued)

SYMBOL	NAME	DESCRIPTION
TIM	Timer-Counter Register	TIM contains the current 16-bit count of the timer. Reset initializes the TIM to FFFFh.
TREG	Temporary Register	16-bit register holds one of the operands for the multiply operations. TREG holds the dynamic shift count for the LACT, ADDT, and SUBT instructions. TREG holds the dynamic bit position for the BITT instruction.

architectural overview

The 'C206 advanced Harvard-type architecture maximizes the processing power by maintaining two separate memory bus structures—program and data—for full-speed execution. The multiple buses allow data and instructions to be read simultaneously. Instructions support data transfers between the two spaces. This architecture permits coefficients stored in program memory to be read in RAM, eliminating the need for a separate coefficient RAM. This, coupled with a four-instruction deep pipeline, allows the TMS320C206/TMS320LC206 to execute most instructions in a single cycle.

status and control registers

Two status registers, ST0 and ST1, contain the status of various conditions and modes. These registers can be stored into data memory and loaded from data memory, thus allowing the status of the machine to be saved and restored for subroutines.

The load-status register (LST) instruction is used to write to ST0 and ST1 (except the INTM bit which is not affected by the LST instruction). The store-status register (SST) instruction is used to read from the ST0 and ST1. The individual bits of these registers can be set or cleared by the SETC and CLRC instructions. Figure 1 shows the organization of status registers ST0 and ST1, indicating all status bits contained in each. Several bits in the status registers are reserved and are read as logic 1s. See Table 4 for status-register field definitions.

Figure 1. Status and Control Register Organization

status and control registers (continued)

Table 4. Status Register Field Definitions

FIELD	FUNCTION
ARB	Auxiliary register pointer buffer. Whenever the ARP is loaded, the old ARP value is copied to the ARB except during an LST instruction. When the ARB is loaded by an LST #1 instruction, the same value is also copied to the ARP.
ARP	Auxiliary register pointer. ARP selects the auxiliary register (AR) to be used in indirect addressing. When the ARP is loaded, the old ARP value is copied to the ARB register. ARP can be modified by memory-reference instructions when using indirect addressing, and by the LARP, MAR, and LST instructions. The ARP is also loaded with the same value as ARB when an LST #1 instruction is executed.
C	Carry bit. C is set to 1 if the result of an addition generates a carry, or reset to 0 if the result of a subtraction generates a borrow. Otherwise, C is reset after an addition or set after a subtraction, except if the instruction is ADD or SUB with a 16-bit shift. In these cases, the ADD can only set and the SUB only reset the carry bit, but cannot affect it otherwise. The single-bit shift and rotate instructions also affect C, as well as the SETC, CLRC, and LST #1 instructions. Branch instructions have been provided to branch on the status of C. C is set to 1 on a reset.
CNF	On-chip RAM configuration-control bit. If CNF is set to 0, the reconfigurable data DARAM blocks are mapped to data space; otherwise, they are mapped to program space. The CNF can be modified by the SETC CNF, CLRC CNF, and LST #1 instructions. RS sets the CNF to 0.
DP	Data memory page pointer. The 9-bit DP register is concatenated with the seven LSBs of an instruction word to form a direct memory address of 16 bits. DP can be modified by the LST and LDP instructions.
INTM	Interrupt-mode bit. When INTM is set to 0, all unmasked interrupts are enabled. When set to 1, all maskable interrupts are disabled. INTM is set and reset by the SETC INTM and CLRC INTM instructions. INTM has no effect on the nonmaskable RS and NMI interrupts. Note that INTM is unaffected by the LST instruction. This bit is set to 1 when a maskable interrupt is acknowledged or when RS is asserted.
OV	Overflow-flag bit. As a latched overflow signal, OV is set to 1 when overflow occurs in the ALU. Once an overflow occurs, the OV remains set until a reset, BCND/D on OV/NOV, or LST instruction clears OV.
OVM	Overflow-mode bit. When OVM is set to 0, overflowed results overflow normally in the accumulator. When set to 1, the accumulator is set to either its most positive or negative value upon encountering an overflow. The SETC and CLRC instructions set and reset this bit, respectively. LST also can be used to modify the OVM.
PM	Product-shift mode. If these two bits are 00, the multiplier's 32-bit product is loaded into the ALU with no shift. If PM = 01, the PREG output is left-shifted one place and loaded into the ALU, with the LSB zero-filled. If PM = 10, the PREG output is left-shifted by four bits and loaded into the ALU, with the LSBs zero-filled. PM = 11 produces a right shift of six bits, sign-extended. Note that the PREG contents remain unchanged. The shift takes place when transferring the contents of the PREG to the ALU. PM is loaded by the SPM and LST #1 instructions. PM is cleared by RS.
SXM	Sign-extension mode bit. SXM = 1 produces sign extension on data as it is passed into the accumulator through the scaling shifter. SXM = 0 suppresses sign extension. SXM does not affect the definitions of certain instructions; for example, the ADDS instruction suppresses sign extension regardless of SXM. SXM is set by the SETC SXM and reset by the CLRC SXM instructions, and can be loaded by the LST #1. SXM is set to 1 by reset.
TC	Test/control flag bit. TC is affected by the BIT, BITT, CMPR, LST #1, and NORM instructions. TC is set to a 1 if a bit tested by BIT or BITT is a 1, if a compare condition tested by CMPR exists between AR (ARP) and AR0, if the exclusive-OR function of the two MSBs of the accumulator is true when tested by a NORM instruction. The conditional branch, call, and return instructions can execute, based on the condition of TC.
XF	XF pin status bit. XF indicates the state of the XF pin, a general-purpose output pin. XF is set by the SETC XF and reset by the CLRC XF instructions. XF is set to 1 by reset.

central processing unit

The TMS320C206/TMS320LC206 central processing unit (CPU) contains a 16-bit scaling shifter, a 16 x16-bit parallel multiplier, a 32-bit central arithmetic logic unit (CALU), a 32-bit accumulator, and additional shifters at the outputs of both the accumulator and the multiplier. This section describes the CPU components and their functions. The functional block diagram shows the components of the CPU.

input scaling shifter

The TMS320C206/TMS320LC206 provides a scaling shifter with a 16-bit input connected to the data bus and a 32-bit output connected to the CALU. This shifter operates as part of the path of data coming from program or data space to the CALU, and requires no cycle overhead. It is used to align the 16-bit data coming from memory to the 32-bit CALU. This is necessary for scaling arithmetic as well as aligning masks for logical operations.

The scaling shifter produces a left shift of 0 to 16 on the input data. The LSBs of the output are filled with zeros; the MSBs may either be filled with zeros or sign-extended, depending upon the value of the SXM bit (sign-extension mode) of status register ST1. The shift count is specified by a constant embedded in the instruction word or by a value in TREG. The shift count in the instruction allows for specific scaling or alignment operations specific to that point in the code. The TREG base shift allows the scaling factor to adapt to the performance of the system.

multiplier

The TMS320C206/TMS320LC206 uses a 16 x 16-bit hardware multiplier that is capable of computing a signed or an unsigned 32-bit product in a single machine cycle. All multiply instructions, except the MPYU (multiply unsigned) instruction, perform a signed-multiply operation. That is, two numbers being multiplied are treated as 2s-complement numbers, and the result is a 32-bit 2s-complement number. There are two registers associated with the multiplier:

- a 16-bit temporary register (TREG) that holds one of the operands for the multiplier, and
- a 32-bit product register (PREG) that holds the product.

Four product shift modes (PM) are available at the PREG output (PSCALE). These shift modes are useful for performing multiply/accumulate operations, performing fractional arithmetic, or justifying fractional products. The PM field of status register ST1 specifies the PM shift mode, as shown in Table 5.

Table 5. PSCALE Product Shift Modes

PM	SHIFT	DESCRIPTION
00	no shift	Product fed to CALU or data bus with no shift
01	left 1	Removes the extra sign bit generated in a 2s-complement multiply to produce a Q31 product
10	left 4	Removes the extra four sign bits generated in a 16 x 13 2s-complement multiply to produce a Q31 product when using the multiply by a 13-bit constant
11	right 6	Scales the product to allow up to 128 product accumulation without the possibility of accumulator overflow

The product can be shifted one bit to compensate for the extra sign bit gained in multiplying two 16-bit 2s-complement numbers (MPY). A four-bit shift is used in conjunction with the MPY instruction with a short immediate value (13 bits or less) to eliminate the four extra sign bits gained in multiplying a 16-bit number by a 13-bit number. Finally, the output of PREG can be right-shifted six bits to enable the execution of up to 128 consecutive multiply/accumulates without the possibility of overflow.

The LT (load TREG) instruction normally loads TREG to provide one operand (from the data bus), and the MPY (multiply) instruction provides the second operand (also from the data bus). A multiplication can also be performed with a 13-bit immediate operand when using the MPY instruction. A product is then obtained every two cycles. For efficient implementation of multiple products, or multiple sums of products, the CPU provides pipelining of the TREG load operation with certain CALU operations which use the PREG. These operations include: load ACC with PREG (LTP); add PREG to ACC (LTA); add PREG to ACC and shift TREG input data to next address in data memory (LTD); and subtract PREG from ACC (LTS).

multiplier (continued)

Two multiply/accumulate instructions (MAC and MACD) fully utilize the computational bandwidth of the multiplier, allowing both operands to be processed simultaneously. The data for these operations can be transferred to the multiplier each cycle by way of the program and data buses. This facilitates single-cycle multiply/accumulates when used with the repeat (RPT) instruction. In these instructions, the coefficient addresses are generated by program-address generation (PAGEN), while the data addresses are generated by data-address generation (DAGEN). This allows the repeated instruction to access the values sequentially from the coefficient table and step through the data in any of the indirect addressing modes.

The MACD instruction, when repeated, supports filter constructs (weighted running averages) so that as the sum-of-products is executed, the sample data is shifted in memory to make room for the next sample and to discard the oldest sample.

The MPYU instruction performs an unsigned multiplication, which greatly facilitates extended-precision arithmetic operations. The unsigned contents of TREG are multiplied by the unsigned contents of the addressed data-memory location, with the result placed in PREG. This allows the operands of greater than 16 bits to be broken down into 16-bit words and processed separately to generate products of greater than 32 bits. The SQRA (square/add) and SQRS (square/subtract) instructions pass the same value to both inputs of the multiplier for squaring a data-memory value.

After the multiplication of two 16-bit numbers, the 32-bit product is loaded into the 32-bit product register (PREG). The product from PREG can be transferred to the CALU or to data memory through the SPH (store product high) and SPL (store product low) instructions. Note: the transfer of PREG to either the CALU or data memory passes through the PSCALE shifter and is therefore, affected by the product-shift mode value defined by the PM bits in the ST1 register. This is important when saving PREG in an interrupt-service routine context save as the PSCALE shift effects cannot be modeled in the restore operation. PREG can be cleared by executing the MPY #0 instruction. The product register can be restored by loading the saved low half into TREG and executing a MPY #1 instruction. The high half is then loaded using the LPH instruction.

central arithmetic logic unit

The TMS320C206/TMS320LC206 CALU implements a wide range of arithmetic and logical functions, the majority of which execute in a single clock cycle. This arithmetic/logic unit (ALU) is referred to as central to differentiate it from a second ALU used for indirect address generation called the auxiliary register arithmetic unit (ARAU). Once an operation is performed in the CALU, the result is transferred to the accumulator (ACC) where additional operations, such as shifting, may occur. Data that is input to the CALU can be scaled by ISCALE when coming from one of the data buses (DRDB or PRDB) or scaled by PSCALE when coming from the multiplier.

The CALU is a general-purpose ALU unit that operates on 16-bit words taken from data memory or derived from immediate instructions. In addition to arithmetic operations, the CALU can perform Boolean operations, facilitating the bit-manipulation ability required for a high-speed controller. One input to the CALU is always provided from the accumulator, and the other input can be provided from the product register (PREG) of the multiplier or from the output of the scaling shifter (that has been read from data memory or from the ACC). After the CALU has performed the arithmetic or logical operation, the result is stored in the accumulator.

The TMS320C206/TMS320LC206 supports floating-point operations for applications requiring a large dynamic range. The NORM (normalization) instruction is used to normalize fixed-point numbers contained in the accumulator by performing left shifts. The four bits of the TREG define a variable shift through the scaling shifter for the LACT/ADDT/SUBT (load/add to/subtract from accumulator with shift specified by TREG) instructions. These instructions are useful in floating-point arithmetic where denormalization of a number is required (that is, floating-point to fixed-point conversion). They are also useful in the implementation of automatic-gain control (AGC) at the input of a filter. The BITT (bit test) instruction provides testing of a single bit of a word in data memory based on the value contained in the four LSBs of TREG.

central arithmetic logic unit (continued)

The CALU overflow-saturation mode can be enabled/disabled by setting/resetting the OVM bit of ST0. Setting the OVM status-register bit selects the overflow-saturation mode. When the CALU is in the overflow-saturation mode and an overflow occurs, the overflow flag is set and the accumulator is loaded with either the most positive or the most negative value representable in the accumulator, depending upon the direction of the overflow. The value of the accumulator upon saturation is 07FFFFFFh (positive) or 08000000h (negative). If the OVM (overflow mode) status register bit is reset and an overflow occurs, the overflowed results are loaded into the accumulator without modification. (Logical operations cannot result in overflow.)

The CALU can execute a variety of branch instructions that depend on the status of the CALU and accumulator. These instructions can be executed conditionally, based on various combinations of the associated status bits. For overflow management, these conditions include the OV (branch on overflow) and EQ (branch on accumulator equal to zero). In addition, the BACC (branch to address in accumulator) instruction provides the ability to branch to an address specified by the accumulator (computed goto). Bit-test instructions (BIT and BITT), which do not affect the accumulator, allow the testing of a specified bit of a word in data memory.

The CALU also has a carry bit (bit 9 of status register ST1) that facilitates efficient computation of extended-precision products and additions or subtractions. The carry bit is also useful in overflow management. The carry bit is affected by the following operations:

- Additions to and subtractions from the accumulator:
 - C = 0: When the result of a subtraction generates a borrow.

When the result of an addition does not generate a carry. (Exception: When the ADD instruction is used with a shift of 16 and no carry is generated, the ADD instruction has no effect on C.)
 - C = 1: When the result of an addition generates a carry.

When the result of a subtraction does not generate a borrow. (Exception: When the SUB instruction is used with a shift of 16 and no borrow is generated, the SUB instruction has no effect on C.)
- Single-bit shifts and rotations of the accumulator value. During a left shift or rotation, the most significant bit of the accumulator is passed to C; during a right shift or rotation, the least significant bit is passed to C.

Note: the carry bit is set to “1” on a hardware reset.

The ADDC (add to accumulator with carry) and SUBB (subtract from accumulator with borrow) instructions use the previous value of carry in their addition/subtraction operation.

accumulator

The 32-bit accumulator is the registered output of the CALU. It can be split into two 16-bit segments for storage in data memory. Shifters at the output of the accumulator provide a left shift of 0 to 7 places. This shift is performed while the data is being transferred to the data bus for storage. The contents of the accumulator remain unchanged. When the post-scaling shifter is used on the high word of the accumulator (bits 16–31), the MSBs are lost and the LSBs are filled with bits shifted in from the low word (bits 0–15). When the postscaling shifter is used on the low word, the LSBs are zero-filled.

The SFL and SFR (in-place one-bit shift to the left/right) instructions and the ROL and ROR (rotate to the left/right) instructions implement shifting or rotating of the accumulator contents through the carry bit. The SXM bit affects the definition of the SFR (shift accumulator right) instruction. When SXM = 1, SFR performs an arithmetic right shift, maintaining the sign of the accumulator data. When SXM = 0, SFR performs a logical shift, shifting out the LSBs and shifting in a zero for the MSB. The SFL (shift accumulator left) instruction is not affected by the SXM bit and behaves the same way in both cases, shifting out the MSB and shifting in a zero. Repeat (RPT) instructions can be used with the shift and rotate instructions for multiple-bit shifts.

auxiliary registers and auxiliary-register arithmetic unit (ARAU)

The 'C206 provides a register file containing eight auxiliary registers (AR0–AR7). The auxiliary registers are used for indirect addressing of the data memory or for temporary data storage. For indirect data-memory addressing, the address of the desired memory location is placed into the selected auxiliary register. These registers are referenced with a 3-bit auxiliary register pointer (ARP) that is loaded with a value from 0 through 7, designating AR0 through AR7, respectively. The auxiliary registers and the ARP can be loaded from data memory, the ACC, the product register, or by an immediate operand defined in the instruction. The contents of these registers can also be stored in data memory or used as inputs to the CALU.

The auxiliary register file (AR0–AR7) is connected to the auxiliary register arithmetic unit (ARAU). The ARAU can autoindex the current auxiliary register while the data-memory location is being addressed. Indexing either by ± 1 or by the contents of the AR0 register can be performed. As a result, accessing tables of information does not require the CALU for address manipulation; thus, the CALU is free for other operations in parallel.

memory

The 'C206 implements three separate address spaces for program memory, data memory, and I/O. Each space accommodates a total of 64K 16-bit words. Within the 64K words of data space, the 256 to 32K words at the top of the address range can be defined to be external global-memory in increments of powers of two, as specified by the contents of the global-memory allocation register (GREG). Access to global memory is arbitrated using the global-memory bus request (\overline{BR}) signal.

On the 'C206, the first 96 (0–5Fh) data-memory locations are allocated for memory-mapped registers or reserved. This memory-mapped register space contains various control and status registers including those for the CPU.

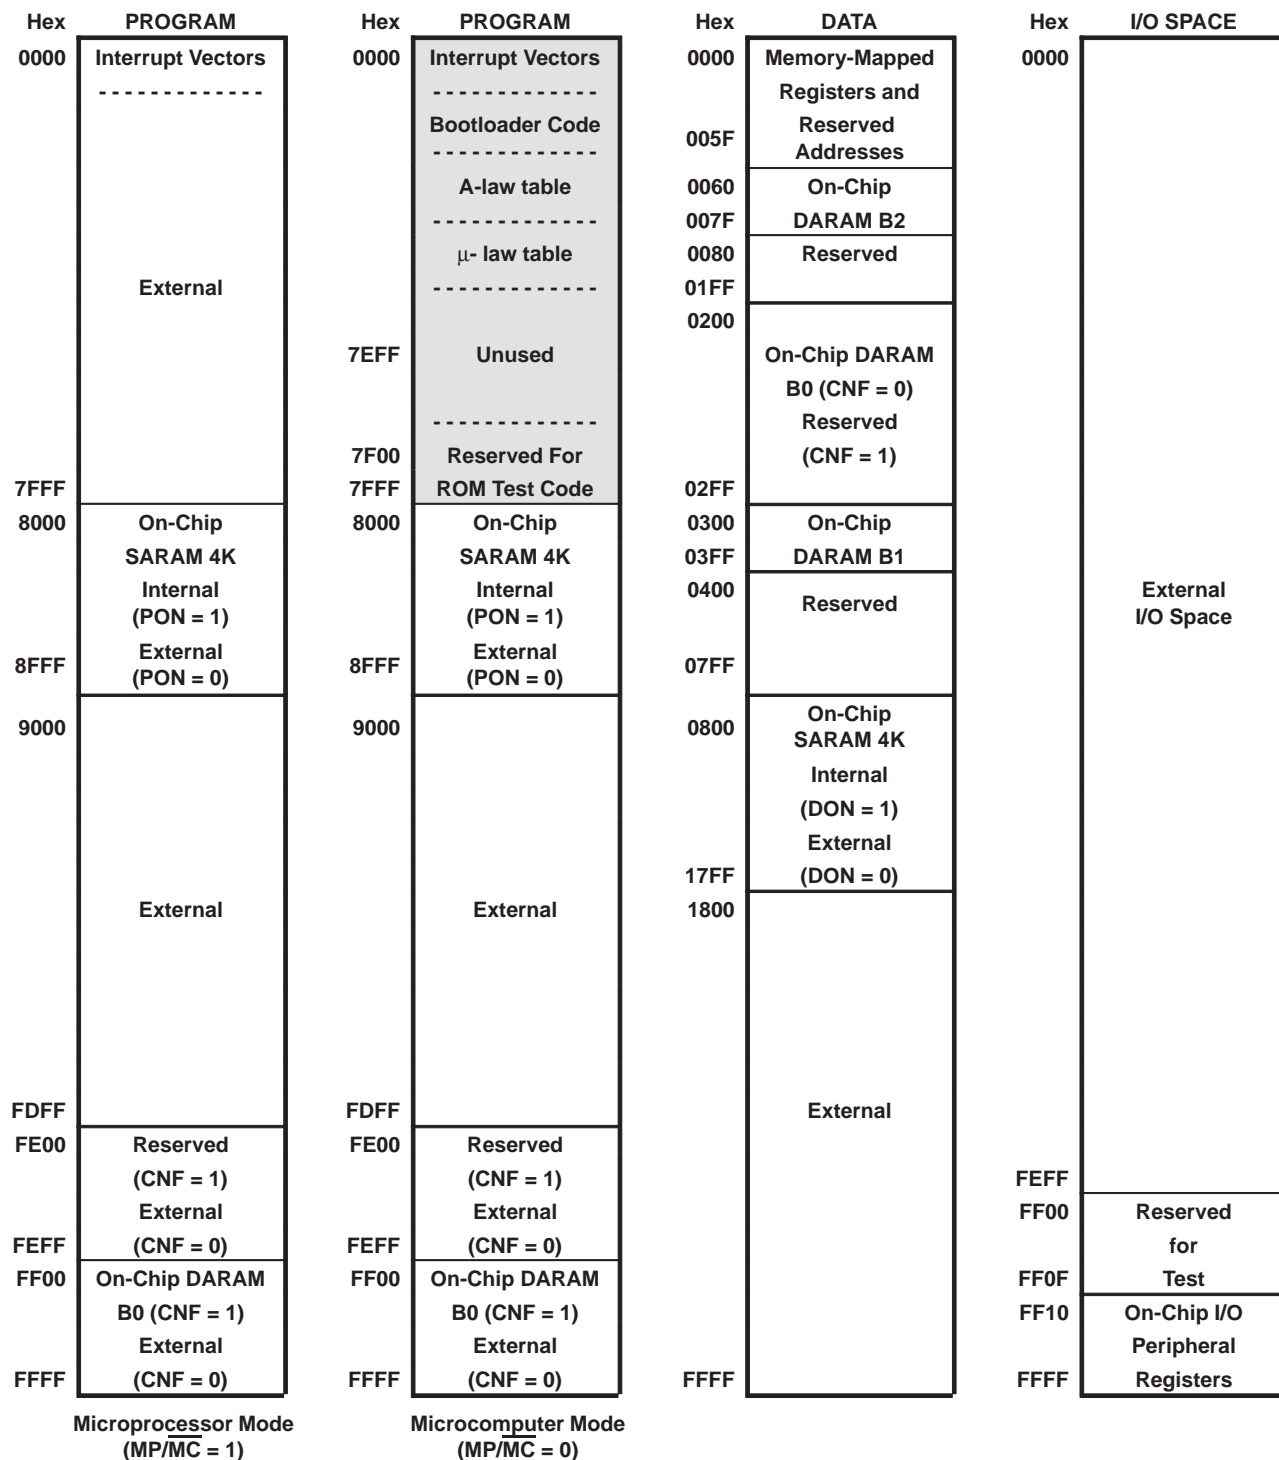

The on-chip memory of the 'C206 includes 544 x 16 words of dual-access RAM (DARAM), 4K x 16 single-access RAM (SARAM), and 32K x 16 program ROM memory. Table 6 shows the mapping of these memory blocks and the appropriate control bits and pins. Figure 2 shows the effects of the memory control pin $\overline{MP/MC}$ and the control bit CNF on the mapping of the respective memory spaces to on-chip or off-chip. The PON and DON bits select the SARAM (4K) mapping in program, data, or both. See Table 9 for details on the PMST register, the PON bit, and the DON bit. At reset, these bits are 11, and the on-chip SARAM is mapped in both the program and data space. The SARAM addresses (800h in data and 8000h in program memory) are accessible in external memory space, if the on-chip SARAM is not enabled.

At reset, if the $\overline{MP/MC}$ pin is held high, the device starts in microprocessor mode and branches to 0000h in external program space. The $\overline{MP/MC}$ pin status is latched in the PMST register (bit 0). As long as this bit remains high, the device is in microprocessor mode. PMST register bits can be read and modified in software. If bit 0 is cleared to 0, the device enters microcomputer mode and program memory addresses from 0000h to 7FFFh map to on-chip ROM.

If the $\overline{MP/MC}$ pin is held low during reset, the device starts in microcomputer mode and branches to 0000h in the on-chip ROM mapped in program space. The on-chip ROM could either contain the bootloader or customer-specific application code which is then executed.

The on-chip data memory blocks B0 and B1 are 256×16 words each. When CNF = 0, B0 is mapped in data space at addresses 0200–02FFh. When CNF = 1, B0 is mapped in program space at addresses 0FF00–0FFFFh. The B1 block is always mapped in data space at addresses 0300–03FFh, and B2 block is always mapped in a data space at addresses 60–7Fh.

memory (continued)

† Standard ROM devices will come with boot code and the A-law, μ -law table.

Figure 2. TMS320C206/TMS320LC206 Memory Map Configurations

memory (continued)

Table 6. TMS320C206/TMS320LC206 Memory Map

DESCRIPTION OF MEMORY BLOCK	DATA MEMORY ADDRESS	PROG MEMORY ADDRESS	MP/MC†	DON†	PON†	CNF BIT†
256 x 16 word dual-access RAM (DARAM) (B0)	200h – 2FFh	–	x	x	x	0
256 x 16 word DARAM (B0)	–	FF00h – FFFFh	x	x	x	1

† The “x” denotes a “don’t care” condition.

‡ The single 4K on-chip SARAM block is accessible from both data and program memory space.

on-chip ROM

The mask-programmable ROM is located in program memory space. Customers can arrange to have this ROM programmed with contents unique to any particular application. The ROM is enabled or disabled by the state of the MP/MC control input upon resetting the device. In microcomputer mode (MP/MC = 0), the ROM occupies the block of program memory from addresses 0000–7FFFh. (Note: the last 100h words, 7F00–7FFFh, are reserved for test.) When in microprocessor mode (MP/MC = 1), addresses 0000h–7FFFh are located in the device’s external program memory space.

bootloader

A bootloader is available in the standard 'C206/LC206 on-chip ROM. This bootloader can be used to automatically transfer user code from an external source to program memory at power up. If MP/MC of the device is sampled low during a hardware reset, execution begins at location 0000h of the on-chip ROM. This location contains a branch instruction to the start of the bootloader program. User code can be transferred to the DSP program memory using any one of the following options:

- 8-bit transfer through the Synchronous Serial Port (SSP)
- 8-bit transfer through the Asynchronous Serial Port (ASP)
- 8/16-bit external EPROM
- 8/16-bit parallel port mapped to I/O space address 0001h of the DSP
- Warm boot option

The standard 'C206/LC206 on-chip ROM also contains the A-law, μ -law table in addition to the bootloader. (The A-law table starts at 0400h, and the μ -law table starts at 0500h.)

bootloader (continued)

The required option is chosen by the state of the EXT8 pin during power up and with the help of a boot routine selection (BRS) word, which is read from I/O address 0000h. The lower 8 bits of the word specify which bootloader option is to be executed. The BRS word uses a 6-bit source address field (SRCE_AD) in parallel EPROM mode and a 6-bit entry address field (ADDR_bb) in warm boot mode to arrive at the starting address of the code. The state of the MP/MC and EXT8 pins is copied into the PMST register. Table 7 describes the bootloader options that can be chosen by the EXT8 pin. Table 8 describes the options available in the 'C206 enhanced bootloader and the bit values of the BRS word to select modes.

Table 7. Bootloader Pin Configurations

MP/MC	EXT8	OPTION	MODES
0	0	Use 'C203 style bootloader	1
0	1	Use 'C206 enhanced bootloader	2 to 9
1	0	EXT8 has no effect	–
1	1	EXT8 has no effect	–

Table 8. 'C206 Bootloader Options

BRS WORD AT I/O 0000h			BOOTLOADER OPTION	MODE
xxxxxxx	xxx0	0000	8-bit serial SSP, ext FSX, CLKX	2
xxxxxxx	xxx0	0100	16-bit serial SSP, ext FSX, CLKX	3
xxxxxxx	xxx0	1000	8-bit parallel I/O	4
xxxxxxx	xxx0	1100	16-bit parallel I/O	5
xxxxxxx	xxx1	0000	8-bit ASP/UART	6

on-chip registers

The TMS320C206/TMS320LC206 includes three registers mapped to internal data space and sixteen (16) registers mapped to internal I/O space. Table 9 describes these registers and shows their respective addresses. In the table, DS[†] refers to data space and IS[†] refers to I/O space.

Table 9. On-Chip Memory and I/O Mapped Registers

NAME	ADDRESS†	VALUE AT RESET‡	DESCRIPTION															
IMR	DS@0004	0000h	Interrupt-mask register. This seven-bit register individually masks or enables the seven interrupts. Bit 0 shares external interrupt <u>INT1</u> and <u>HOLD</u> . <u>INT2</u> and <u>INT3</u> share bit 1. Bit 2 ties to the timer interrupt, <u>TINT</u> . Bits 3 and 4, <u>RINT</u> and <u>XINT</u> , respectively, are for the synchronous serial port, SSP. Bit 5, <u>TXRXINT</u> , shares the transmit and receive interrupts for the asynchronous serial port, ASP. Bit 6 is reserved for monitor-mode-emulation operations and must always be set to 0 except in conjunction with emulation-monitor operations. Bits 7 – 15 are not used in the TMS320C206/TMS320LC206. IMR is set to 0 at reset. A bit value of 0 disables an interrupt, and a value of 1 enables an interrupt.															
GREG	DS@0005	0000h	Global-memory allocation register. This 8-bit register specifies the size of the global memory space. GREG is set to 0 at reset.															
IFR	DS@0006	0000h	Interrupt-flag register. The seven-bit IFR indicates that the TMS320C206/TMS320LC206 has latched an interrupt from one of the seven maskable interrupts. Bit 0 shares external interrupt <u>INT1</u> and <u>HOLD</u> . <u>INT2</u> and <u>INT3</u> share bit 1. Bit 2 ties to the timer interrupt, <u>TINT</u> . Bits 3 and 4, <u>RINT</u> and <u>XINT</u> , respectively, are for the SSP. Bit 5, <u>TXRXINT</u> , shares the transmit and receive interrupts for the ASP. Bit 6 is reserved for monitor-mode-emulation operations and must always be set to 0 except in conjunction with emulation-monitor operations. Writing a 1 to the respective interrupt bit clears an active flag and the respective pending interrupt. Writing a 1 to an inactive flag has no effect. Bits 7 – 15 are not used in the TMS320C206/TMS320LC206. IFR is set to 0 at reset.															
PMST	IS@FFE4	0006h	<p>Bit 0 - Processor mode status bit (PMST). latches in the <u>MP/MC</u> pin at reset. This bit can be written to configure microprocessor (1) or microcomputer mode (0). Bits 1 and 2 configure the SARAM mapping either in program memory, data memory, or both. At reset, these bits are 11, the SARAM is mapped in both program and data space.</p> <table><tr><td>DON (bit 2)</td><td>PON (bit 1)</td><td></td></tr><tr><td>0</td><td>0</td><td>- SARAM not mapped, address in external memory</td></tr><tr><td>0</td><td>1</td><td>- SARAM in on-chip program memory at 0x8000h</td></tr><tr><td>1</td><td>0</td><td>- SARAM in on-chip data memory at 0x800h</td></tr><tr><td>1</td><td>1</td><td>- SARAM in on-chip program and data memory (reset value)</td></tr></table> <p>Bit 3 - <u>LEVEXT8</u> bit. This bit captures the status of the EXT8 pin 1 at reset only.</p> <p>Bit 15 – Fast <u>RD</u>, <u>FRDN</u>. This bit provides software control to select an inverted <u>R/W</u> signal in place of the <u>RD</u> signal (pin 45). This is intended to help achieve zero wait-state memory interface with slow memory devices. At reset, this bit is 0 and selects <u>RD</u> as the signal at pin 45. If the <u>FRDN</u> bit is written with a 1, the read signal at pin 45 is replaced with the inverted <u>R/W</u> signal.</p>	DON (bit 2)	PON (bit 1)		0	0	- SARAM not mapped, address in external memory	0	1	- SARAM in on-chip program memory at 0x8000h	1	0	- SARAM in on-chip data memory at 0x800h	1	1	- SARAM in on-chip program and data memory (reset value)
DON (bit 2)	PON (bit 1)																	
0	0	- SARAM not mapped, address in external memory																
0	1	- SARAM in on-chip program memory at 0x8000h																
1	0	- SARAM in on-chip data memory at 0x800h																
1	1	- SARAM in on-chip program and data memory (reset value)																
CLK	IS@FFE8	0000h	CLKOUT1 on or off. At reset, this bit is configured as a zero for the CLKOUT1 pin to be active. If this bit is a 1, CLKOUT1 pin is turned off.															
ICR	IS@FFEC	0000h	<u>Interrupt-control</u> register. This register is used to <u>determine which</u> interrupt is active since <u>INT1</u> and <u>HOLD</u> share the same interrupt vector as <u>INT2</u> and <u>INT3</u> . A portion of this register is for mask/unmask (similar to IFR). At reset, all bits are zeroed, thereby allowing the <u>HOLD</u> mode to be enabled. The <u>MODE</u> bit is used by the hold-generating circuit to determine if a <u>HOLD</u> or <u>INT1</u> is active.															

[†] DS = data space and IS = input/output ports

[‡] 'x' indicates undefined or value based on the pin levels at reset.

on-chip registers (continued)

Table 9. On-Chip Memory and I/O Mapped Registers (Continued)

NAME	ADDRESS†	VALUE AT RESET‡	DESCRIPTION
SDTR	IS@FFF0	xxxxh	Synchronous serial port (SSP) transmit and receive register
SSPCR	IS@FFF1	0030h	Synchronous serial-port control register. This register controls serial-port operation as defined by the register bits.
SSPST	IS@FFF2	0000h	Synchronous serial-port status register
SSPMC	IS@FFF3	0000h	Synchronous serial-port multichannel register
ADTR	IS@FFF4	xxxxh	Asynchronous serial port (ASP) transmit and receive register
ASPCR	IS@FFF5	0000h	Asynchronous serial-port control register. This register controls the asynchronous serial-port operation.
IOSR	IS@FFF6	18xxh	I/O-status register. IOSR is used for detecting current levels on pins IO0–IO3 when defined as inputs.
BRD	IS@FFF7	0001h	Baud-rate generator. 16-bit register used to determine baud rate of UART. No data is transmitted/received if BRD is zero.
TCR	IS@FFF8	0000h	Timer-control register. This ten-bit register contains the control bits that define the divide-down ratio, start/stop the timer, and reload the period. Also contained in this register is the current count in the prescaler. Reset initializes the timer divide-down ratio to 0 and starts the timer.
PRD	IS@FFF9	FFFFh	Timer-period register. This 16-bit register contains the 16-bit period that is loaded into the timer counter when the counter borrows or when the reload bit is activated. Reset initializes the PRD to 0xFFFF.
TIM	IS@FFFA	FFFFh	Timer-counter register. This 16-bit register contains the current 16-bit count of the timer. Reset initializes the TIM to 0xFFFF.
SSPCT	IS@FFFB	0000h	Synchronous serial-port counter register.
WSGR	IS@FFFC	0FFFh	Wait-state generator register. This register contains 12 control bits to enable 0 to 7 wait states to program, data, and I/O space. Reset initializes WSGR to 0x0FFFh.

† DS = data space and IS = input/output ports

‡ 'x' indicates undefined or value based on the pin levels at reset.

external interface

The 'C206 devices can address up to $64K \times 16$ words of memory (or registers) in each of the program, data, and I/O spaces. On-chip memory, when enabled, occupies some of this off-chip range. In data space, the high 32K words can be mapped dynamically either locally or globally using the GREG register as described in the *TMS320C20x User's Guide* (literature number SPRU127). A data-memory access that is mapped as global asserts \overline{BR} low (with timing similar to the address bus).

The CPU of the 'C206 schedules a program fetch, data read, and data write on the same machine cycle. This is because from on-chip memory, the CPU can execute all three of these operations in the same cycle. However, the external interface multiplexes the internal buses to one address and one data bus. The external interface sequences these operations to complete first the data write, then the data read, and finally the program read.

The 'C206 supports a wide range of system-interfacing requirements. Program, data, and I/O address spaces provide interface to memory and I/O, thus maximizing system throughput. The full 16-bit address and data bus, along with the \overline{PS} , \overline{DS} , and \overline{IS} space-select signals, allow addressing of 64K 16-bit words in each of the three spaces.

I/O design is simplified by having I/O treated the same way as memory. I/O devices are mapped into the I/O address space using the processor's external address and data buses in the same manner as memory-mapped devices.

external interface (continued)

The 'C206 external parallel interface provides various control signals to facilitate interfacing to the device. The $\overline{R/W}$ output signal is provided to indicate whether the current cycle is a read or a write. The \overline{STRB} output signal provides a timing reference for all external cycles. For convenience, the device also provides the \overline{RD} and the \overline{WE} output signals, which indicate a read and a write cycle, respectively, along with timing information for those cycles. The availability of these signals minimizes external gating necessary for interfacing external devices to the 'C206.

Interface to memory and I/O devices of varying speeds is accomplished by using the READY line. When transactions are made with slower devices, the 'C206 processor waits until the other device completes its function and then signals the processor via the READY line. Once a ready indication is provided back to the 'C206 from the external device, execution continues.

The bus request (\overline{BR}) signal is used in conjunction with the other 'C206 interface signals to arbitrate external global memory accesses. Global memory is external data-memory space in which the \overline{BR} signal is asserted at the beginning of the access. When an external global memory device receives the bus request, it responds by asserting the READY signal after the global memory access is arbitrated and the global access is completed.

The TMS320C206/TMS320LC206 supports zero-wait-state reads on the external interface. However, to avoid bus conflicts, writes take two cycles. This allows the TMS320C206/TMS320LC206 to buffer the transition of the data bus from input to output (or from output to input) by a half cycle. In most systems, TMS320C206/TMS320LC206 ratio of reads to writes is significantly large to minimize the overhead of the extra cycle on writes.

Wait states can be generated when accessing slower external resources. The wait states operate on machine-cycle boundaries and are initiated either by using READY or by using the software wait-state generator. READY can be used to generate any number of wait states.

interrupts and subroutines

The 'C206 implements three general-purpose interrupts, $\overline{INT3}$ – $\overline{INT1}$, along with reset (\overline{RS}), and the nonmaskable interrupt (\overline{NMI}), which are available for external devices to request the attention of the processor. Internal interrupts are generated by the synchronous serial port (RINT and XINT), by the timer (TINT), UART, (TXRXINT), and by the software-interrupt (TRAP, INTR and NMI) instructions. Interrupts are prioritized, with \overline{RS} having the highest priority, (followed by \overline{NMI}), and UART having the lowest priority. Additionally, any interrupt except \overline{RS} and \overline{NMI} can be individually masked with a dedicated bit in the interrupt mask register (IMR) and can be cleared, set, or tested using its own dedicated bit in the interrupt flag register (IFR). The reset and NMI functions are not maskable.

All interrupt vector locations are on two-word boundaries so that branch instructions can be accommodated in those locations if desired.

A built-in mechanism protects multicycle instructions from interrupts. If an interrupt occurs during a multicycle instruction, the interrupt is not processed until the instruction completes execution. This mechanism applies to instructions that are repeated (using the RPT instruction) and to instructions that become multicycle because of wait states.

Each time an interrupt is serviced or a subroutine is entered, the program counter (PC) is pushed onto an internal hardware stack, providing a mechanism for returning to the previous context. The stack contains eight locations, allowing interrupts or subroutines to be nested up to eight levels deep.

reset

The 'C206 utilizes an active-low reset (\overline{RS} and \overline{PLLRS}) input for the core, peripherals, and PLL.

A minimum pulse duration of six cycles ensures that an asynchronous reset signal properly resets the device. The 'C206 fetches its first instruction approximately sixteen cycles after the rising edge of \overline{RS} .

The reset action halts all operations whether they are complete or not; therefore, the state of the system and its data cannot be maintained through the reset operation. For example, if the device is writing to an external resource when the reset is initiated, the write is aborted; this may corrupt the contents or configuration of system resources. Therefore, it is necessary to reinitialize the system after a reset.

power-down modes

The 'C206 implements a power-down mode in which the 'C206 core enters a dormant state and dissipates less power. The power-down mode is invoked by executing an IDLE instruction. While the device is in power-down mode, the on-chip peripherals continue to operate.

While the 'C206 is in a power-down mode, all of its internal contents are maintained; this allows operation to continue unaltered when the power-down mode is terminated. All CPU activities are halted when the IDLE instruction is executed, but the CLKOUT1 pin remains active depending on the status of the CLKOUT1-pin control register (CLK). The peripheral circuits continue to operate, allowing peripherals such as serial ports and timers to take the CPU out of its powered-down state. The power-down mode, when initiated by an IDLE instruction, is terminated upon receipt of an interrupt.

software-controlled wait-state generator

Due to the fast cycle time of the 'C206 devices, it is often necessary to operate with wait states to interface with external logic or memory. For many systems, one wait state is adequate.

The software wait-state generator can be programmed to generate between zero and seven wait states for a given space. Software wait states are configured by way of the wait-state generator register (WSGR). The WSGR includes four 3-bit fields to configure wait states for the following external memory spaces: data space (DSWS), upper program space (PSUWS), lower program space (PSLWS), and I/O space (ISWS). The wait-state generator enables wait states for a given memory space based on the value of the corresponding three bits, regardless of the condition of the READY signal. The READY signal can be used to generate additional wait states. All bits of the WSGR are set to 1 at reset, so that the device can operate from slow memory immediately after reset. The WSGR register (shown in Figure 4) resides at I/O port FFFCh. See Table 7 for the bit settings of the various fields in the WSGR for wait-state programming. See Table 8 for a description of the various WSGR fields.

001	1
010	2
011	3
100	4
101	5
110	6
111	7

Table 11. 'C206 Wait-State Generator Register (WSGR)

BITS	NAME	DESCRIPTION
2–0	PSLWS	External program-space wait states (lower). PSLWS determines that between 0 to 7 wait states are applied to all reads and writes to off-chip lower program-space address (0h–7FFFh). The memory cycle can be further extended using the READY signal. The READY signal does not override the wait states generated by PSLWS. These bits are set to 1 (active) by reset (\overline{RS}).
5–3	PSUWS	External program-space wait states (upper). PSUWS determines that between 0 to 7 wait states are applied to all reads and writes to off-chip upper program space address (8000h–0FFFFh). The memory cycle can be further extended using the READY signal. The READY signal does not override the wait states generated by PSUWS. These bits are set to 1 (active) by reset (\overline{RS}).
8–6	DSWS	External data space wait states. DSWS determines that between 0 to 7 wait states are applied to all reads and writes to off-chip data space. The memory cycle can be further extended using the READY signal. The READY signal does not override the wait states generated by DSWS. These bits are set to 1 (active) by reset (\overline{RS}).
11–9	ISWS	External input / output-space wait state. ISWS determines that between 0 to 7 wait states are applied to all reads and writes to off-chip I/O space. The memory cycle can be further extended using the READY signal. The READY signal does not override the wait states generated by ISWS. These bits are set to 1 (active) by reset (\overline{RS}).
15–12	Reserved	Don't care. Always read as 0.

timer

The TMS320C206/TMS320LC206 includes a 20-bit timer, implemented with a 16-bit main counter (TIM), and a 4-bit prescaler counter (PSC). The count values are written into the 16-bit period register (PRD), and the 4-bit timer divide-down register (TDDR). The TIM and the PRD are 16-bit registers mapped to I/O space, while the PSC and the TDDR are 4-bit fields of the timer control register (TCR). The TCR is an I/O mapped register which also includes other control bits for the timer (see Table 9).

When the timer is started, the TIM is loaded with the contents of PRD, and the PSC is loaded with the contents of the TDDR. The PSC is decremented by one at each CLKOUT1 cycle. On the CLKOUT1 cycle after the PSC decrements to zero, the PSC is reloaded with the contents of TDDR, and the TIM is decremented by one. That is, every (TDDR+1) CLKOUT1 cycles, the TIM is decremented by one. When the TIM decrements to zero, it is reloaded with the contents of the PRD on the following CLKOUT1 cycle, and a new timer interval begins. Therefore, the timer interrupt rate is defined as follows: $\text{CLKOUT1 frequency} / [(TDDR+1) (PRD+1)]$.

The timer can be used to generate periodic CPU interrupts based on CLKOUT1. Each time the TIM decrements to zero, a timer interrupt (TINT) is generated, and a pulse equal to the duration of a CLKOUT1 cycle is generated on the TOUT pin. The timer provides a convenient means of performing periodic I/O, context switching, or other functions.

input clock options

The TMS320C206/TMS320LC206 provides multiple clock modes of divide-by-two and multiply-by-one, -two, or -four. The clock mode configuration cannot be dynamically changed without executing another reset.

synchronous serial port

A full duplex (bidirectional) 8-bit or 16-bit on-chip synchronous serial port provides direct communication with serial devices such as codecs, serial A/D (analog-to-digital) converters, and other serial systems. The interface signals are compatible with codecs and many other serial devices. The serial port can also be used for intercommunication between processors in multiprocessing applications.

For data transmission, three signals are necessary to connect the transmit pins of the transmitting device with the receive pins of the receiving device. The transmitted serial data signal (DX) sends the actual data. The transmit frame synchronization signal (FSX) initiates the transfer (at the beginning of the packet), and the transmit clock signal (CLKX) clocks the bit transfer. The corresponding pins on the receive device are DR, FSR and CLKR, respectively. When the serial port is not used, the device can be configured to shut off the serial port internal clocks, allowing the device to run in a lower power mode of operation.

The continuous mode of the synchronous serial port (SSP) provides operation that, once initiated, requires no further frame synchronization pulses when transmitting at maximum frequency. Both receive and transmit operations have a four-word deep first-in first-out (FIFO) buffer. The advantage of having a FIFO is to alleviate the CPU from being loaded with the task of servicing a receive- or transmit-data operation after each word, allowing a continuous communications stream of 16-bit data packets. The maximum transmission rate for both transmit and receive operations is CPU divided by two or CLKOUT1(frequency)/2. Therefore, the maximum rate at 40 million instructions per second (MIPS) is 20 megabits per second (Mbps). The serial port is fully static and functions at arbitrarily low clocking frequencies. When the serial ports are in reset, the device can be configured to shut off the serial port internal clocks, allowing the device to run in a lower power mode of operation.

The synchronous serial port also has capabilities to facilitate a glueless interface with multiple codecs and other peripherals. The SSP registers are complemented with three registers—status register (SSPST), multichannel register (SSPMC), and counter register (SSPCT). The SSPST includes control and status bits. Additional control bits are provided in the SSPMC to control the multichannel and prescaled clocks/frames features. The SSPCT register contains the two 8-bit prescalers to provide variable synchronous shift clock (CLKX) and frame syncs (FSX).

asynchronous serial port

The asynchronous serial port is full-duplexed and transmits and receives 8-bit data only. For transmit and receive operations, there is one start bit and one or two configurable stop bits by way of the asynchronous serial-port control register (ASPCR). Double-buffering of transmit/receive data is used in all modes. Baud rate generation is accomplished via the baud rate divisor (BRD) register. This port also features an auto-baud-detection logic.

scan-based emulation

TMS320C206/TMS320LC206 devices incorporate scan-based emulation logic for code-development and hardware-development support. Scan-based emulation allows the emulator to control the processor in the system without the use of intrusive cables to the full pinout of the device. The scan-based emulator communicates with the 'C206 by way of the IEEE 1149.1 compatible (JTAG) interface. The TMS320C206 and TMS320LC206 DSPs, like the TMS320F206, TMS320C203, and TMS320LC203, do not include boundary scan. The scan chain of these devices is useful for emulation function only.

multiprocessing

The flexibility of the 'C206 allows configurations to satisfy a wide range of system requirements; the device can be used in a variety of system configurations, including but not limited to the following:

- A standalone processor
- A multiprocessor with devices in parallel
- A slave/host multiprocessor with global memory space
- A peripheral processor interfaced via processor-controlled signals to another device

For multiprocessing applications, the 'C206 has the capability of allocating global memory space and communicating with that space via the \overline{BR} and ready control signals. Global memory is data memory shared by more than one device. Global-memory access must be arbitrated. The 8-bit memory-mapped global memory allocation register (GREG) specifies part of the 'C206's data memory as global external memory. The contents of the register determine the size of the global memory space. If the current instruction addresses an operand within that space, \overline{BR} is asserted to request control of the bus. The length of the memory cycle is controlled by the READY line.

The TMS320C206/TMS320LC206 supports direct memory access (DMA) to its local (off-chip) program, data, and I/O spaces. Two signals, $\overline{HOLD}/\overline{INT1}$, an input to the device, and \overline{HOLDA} , an output, control this mechanism. The Hold feature is enabled by clearing the mode bit in the interrupt control register (ICR IS@FFEC_h). When the Hold feature is enabled, and $\overline{HOLD}/\overline{INT1}$ is asserted, executing an IDLE instruction puts the address, data, and memory control signals (\overline{PS} , \overline{DS} , \overline{IS} , \overline{STRB} , $\overline{R/W}$, and \overline{WE}) in a high-impedance state. When this occurs, the \overline{HOLDA} signal is asserted, acknowledging that the processor has relinquished control of the external bus. It is important to note that when the mode bit is set to one, the Hold feature is disabled, and the $\overline{HOLD}/\overline{INT1}$ pin functions as a general-purpose interrupt ($\overline{INT1}$). That is, when the Hold feature is disabled, and $\overline{HOLD}/\overline{INT1}$ is asserted, the IDLE instruction does not cause the memory interface signals to enter the high-impedance mode, and it does not cause the assertion of \overline{HOLDA} . At reset, the mode bit is cleared to zero, and the Hold feature is enabled.

instruction set

The 'C206 microprocessor implements a comprehensive instruction set that supports both numeric-intensive signal-processing operations and general-purpose applications, such as multiprocessing and high-speed control. Source code for the 'C1x and 'C2x DSPs is upwardly compatible with the 'C206.

For maximum throughput, the next instruction is prefetched while the current one is being executed. Because the same data lines are used to communicate to external data, program, or I/O space, the number of cycles an instruction requires to execute varies depending upon whether the next data operand fetch is from internal or external memory. Highest throughput is achieved by maintaining data memory on chip and using either internal or fast external program memory.

addressing modes

The 'C206 instruction set provides four basic memory-addressing modes: direct, indirect, immediate, and register.

In direct addressing, the instruction word contains the lower seven bits of the data memory address. This field is concatenated with the nine bits of the data-memory-page pointer (DP) to form the 16-bit data memory address. Thus, in the direct-addressing mode, data memory is effectively paged with a total of 512 pages, each page containing 128 words.

Indirect addressing accesses data memory through the auxiliary registers. In this addressing mode, the address of the instruction operand is contained in the currently selected auxiliary register. Eight auxiliary registers (AR0–AR7) provide flexible and powerful indirect addressing. To select a specific auxiliary register, the auxiliary register pointer (ARP) is loaded with a value from 0 to 7 for AR0 through AR7, respectively.

addressing modes (continued)

There are seven types of indirect addressing: autoincrement or autodecrement, postindexing by either adding or subtracting the contents of AR0, single-indirect addressing with no increment or decrement, and bit-reversed addressing [used in Fast Fourier Transforms (FFTs)] with increment or decrement. All operations are performed on the current auxiliary register in the same cycle as the original instruction, following which the current auxiliary register and ARP can be modified.

In immediate addressing, the actual operand data is provided in a portion of the instruction word or words. There are two types of immediate addressing: long and short. In short-immediate addressing, the data is contained in a portion of the bits in a single-word instruction. In long-immediate addressing, the data is contained in the second word of a two-word instruction. The immediate-addressing mode is useful for data that does not need to be stored or used more than once during the course of program execution, such as initialization values, constants, etc.

The register-addressing mode uses operands in CPU registers either explicitly, such as with a direct reference to a specific register, or implicitly, with instructions that intrinsically reference certain registers. In either case, operand reference is simplified because 16-bit values can be used without specifying a full 16-bit operand address or immediate value.

repeat feature

The repeat function can be used with instructions (as defined in Table 13) such as multiply/accumulates (MAC and MACD), block moves (BLDD and BLPD), I/O transfers (IN/OUT), and table read/writes (TBLR/TBLW). These instructions, although normally multicycle, are pipelined when the repeat feature is used, and they effectively become single-cycle instructions. For example, the table-read instruction may take three or more cycles to execute, but when the instruction is repeated, a table location can be read every cycle.

When using the repeat feature, the repeat counter (RPTC) is loaded with the addressed-data-memory location if direct or indirect addressing is used, or an 8-bit immediate value if short-immediate addressing is used. The RPTC register is loaded by the RPT instruction. This results in a maximum of $N + 1$ executions of a given instruction when RPTC is loaded with N . RPTC is cleared by reset. Once a repeat instruction (RPT) is decoded, all interrupts, including NMI (except reset), are masked until the completion of the repeat loop.

instruction set summary

This section summarizes the opcodes of the instruction set for the 'C206 digital signal processor. This instruction set is a superset of the 'C1x and 'C2x instruction sets. The instructions are arranged according to function and are alphabetized by mnemonic within each category. The symbols in Table 12 are used in the instruction set summary table (Table 13). The Texas Instruments 'C20x assembler accepts 'C2x instructions.

The number of words that an instruction occupies in program memory is specified in column 3 of Table 13. Several instructions specify two values separated by a slash mark (/) for the number of words. In these cases, different forms of the instruction occupy a different number of words. For example, the ADD instruction occupies one word when the operand is a short-immediate value or two words if the operand is a long-immediate value.

The number of cycles that an instruction requires to execute is in column 3 of Table 13. All instructions are assumed to be executed from internal program memory (RAM) and internal data dual-access memory. The cycle timings are for single-instruction execution, not for repeat mode.

instruction set summary (continued)

Table 12. Opcode Symbols

SYMBOL	DESCRIPTION															
A	Address															
ACC	Accumulator															
ACCB	Accumulator buffer															
ARx	Auxiliary register value (0–7)															
BITx	4-bit field specifies which bit to test for the BIT instruction															
BMAR	Block-move address register															
DBMR	Dynamic bit-manipulation register															
I	Addressing-mode bit															
II...II	Immediate operand value															
INTM	Interrupt-mode flag bit															
INTR#	Interrupt vector number															
K	Constant															
PREG	Product register															
PROG	Program memory															
RPTC	Repeat counter															
SHF, SHFT	3/4-bit shift value															
TC	Test-control bit															
T P	Two bits used by the conditional execution instructions to represent the conditions TC, NTC, and BIO. <table><tr><td>T</td><td>P</td><td>Meaning</td></tr><tr><td>0</td><td>0</td><td>$\overline{\text{BIO}}$ low</td></tr><tr><td>0</td><td>1</td><td>TC = 1</td></tr><tr><td>1</td><td>0</td><td>TC = 0</td></tr><tr><td>1</td><td>1</td><td>None of the above conditions</td></tr></table>	T	P	Meaning	0	0	$\overline{\text{BIO}}$ low	0	1	TC = 1	1	0	TC = 0	1	1	None of the above conditions
T	P	Meaning														
0	0	$\overline{\text{BIO}}$ low														
0	1	TC = 1														
1	0	TC = 0														
1	1	None of the above conditions														
TREGn	Temporary register n (n = 0, 1, or 2)															
Z L V C	4-bit field representing the following conditions: <table><tr><td>Z:</td><td>ACC = 0</td></tr><tr><td>L:</td><td>ACC < 0</td></tr><tr><td>V:</td><td>Overflow</td></tr><tr><td>C:</td><td>Carry</td></tr></table> <p>A conditional instruction contains two of these 4-bit fields. The 4-LSB field of the instruction is a 4-bit mask field. A 1 in the corresponding mask bit indicates that the condition is being tested. The second 4-bit field (bits 4–7) indicates the state of the conditions designated by the mask bits as being tested. For example, to test for $\text{ACC} \geq 0$, the Z and L fields are set while the V and C fields are not set. The next 4-bit field contains the state of the conditions to test. The Z field is set to indicate testing of the condition $\text{ACC} = 0$, and the L field is reset to indicate testing of the condition $\text{ACC} \geq 0$. The conditions possible with these 8 bits are shown in the BCND and CC instructions. To determine if the conditions are met, the 4-LSB bit mask is ANDed with the conditions. If any bits are set, the conditions are met.</p>	Z:	ACC = 0	L:	ACC < 0	V:	Overflow	C:	Carry							
Z:	ACC = 0															
L:	ACC < 0															
V:	Overflow															
C:	Carry

development support

Texas Instruments offers an extensive line of development tools for the 'x20x generation of DSPs, including tools to evaluate the performance of the processors, generate code, develop algorithm implementations, and fully integrate and debug software and hardware modules.

The following products support development of 'x20x-based applications:

Software Development Tools:

Assembler/Linker
Simulator
Optimizing ANSI C Compiler
Application Algorithms
C/Assembly Debugger and Code Profiler†

Hardware Development Tools:

Emulator XDS510™ (supports 'x20x multiprocessor system debug)

The *TMS320 Family Development Support Reference Guide* (literature number SPRU011) contains information about development-support products for all TMS320 family member devices, including documentation. Refer to this document for further information about TMS320 documentation or any other TMS320 support products from Texas Instruments. There is also an additional document, the *TMS320 Third-Party Support Reference Guide* (literature number SPRU052), which contains information about TMS320-related products from other companies in the industry. To receive copies of TMS320 literature, contact the Literature Response Center at 800/477-8924.

See Table 14 for complete listings of development-support tools for the 'C20x. For information on pricing and availability, contact the nearest TI field sales office or authorized distributor.

† The Texas Instruments C Source Debugger, Revision 1.00.01, is not compatible with 'C206/'LC206 silicon revisions. Contact TI for more information regarding the most recent debugger revision and release.

XDS510 is a trademark of Texas Instruments Incorporated.

device and development-support tool nomenclature

To designate the stages in the product development cycle, Texas Instruments assigns prefixes to the part numbers of all TMS320 devices and support tools. Each TMS320 member has one of three prefixes: TMX, TMP, and TMS. Texas Instruments recommends two of three possible prefix designators for its support tools: TMDX and TMDS. These prefixes represent evolutionary stages of product development from engineering prototypes (TMX/TMDX) through fully qualified production devices/tools (TMS/TMDS). This development flow is defined below.

Device Development Evolutionary Flow:

- TMX** Experimental device that is not necessarily representative of the final device's electrical specifications
- TMP** Final silicon die that conforms to the device's electrical specifications but has not completed quality and reliability verification
- TMS** Fully qualified production device

Support Tool Development Evolutionary Flow:

- TMDX** Development-support product that has not yet completed Texas Instruments internal qualification testing
- TMDS** Fully qualified development-support product

TMX and TMP devices and TMDX development-support tools are shipped against the following disclaimer:

"Developmental product is intended for internal evaluation purposes."

TMS devices and TMDS development-support tools have been fully characterized, and the quality and reliability of the device have been fully demonstrated. Texas Instruments standard warranty applies.

Predictions show that prototype devices (TMX or TMP) will have a greater failure rate than the standard production devices. Texas Instruments recommends that these devices not be used in any production system

TMS320C206, TMS320LC206 DIGITAL SIGNAL PROCESSORS

SPRS065B – JUNE 1998 – REVISED JANUARY 1999

device and development-support tool nomenclature (continued)

because their expected end-use failure rate is still undefined. Only qualified production devices are to be used. TI device nomenclature also includes a suffix with the device family name. This suffix indicates the package type (for example, PZ) and temperature range (for example, A). The following figures provide a legend for reading the complete device name for any TMS320 family member.

[†] For TMS320C206PZ, TMS320LC206PZ devices with this temperature range, L is not printed on package.

[‡] TQFP = Thin Quad Flat Package

[§] The TMS320C203 is a bootloader device without the B option.

Figure 5. TMS320x20x Device Nomenclature

documentation support

Extensive documentation supports all of the TMS320 family generations of devices from product announcement through applications development. The types of documentation available include: data sheets, such as this document, with design specifications; complete user's guides for all devices and development-support tools; and hardware and software applications.

For general background information on DSPs and TI devices, see the three-volume publication *Digital Signal Processing Applications With the TMS320 Family* (literature numbers SPRA012, SPRA016, and SPRA017). Also available is the *Calculation of TMS320C20x Power Dissipation* application report (literature number SPRA088).

For further information regarding the 'C206 and 'LC206, please refer to the *TMS320C20x User's Guide* (literature number SPRU127) and the *TMS320 DSP Development Support Reference Guide* (literature number SPRU011F).

A series of DSP textbooks is published by Prentice-Hall and John Wiley & Sons to support DSP research and education. The TMS320 newsletter, *Details on Signal Processing*, is published quarterly and distributed to update TMS320 customers on product information. The TMS320 DSP bulletin board service (BBS) provides access to information pertaining to the TMS320 family, including documentation, source code, and object code for many DSP algorithms and utilities. The BBS can be reached at 281/274-2323.

Information regarding TI DSP products is also available on the Worldwide Web at <http://www.ti.com> uniform resource locator (URL).

To send comments regarding the 'C206/'LC206 datasheet (SPRS065B), use the comments@books.sc.ti.com email address, which is a repository for feedback. For questions and support, contact the Product Information Center listed at the back of the datasheet.

absolute maximum ratings over operating free-air temperature range (unless otherwise noted)†

Supply voltage range, V_{DD} (see Note 1)	– 0.3 V to 4.6 V
Supply voltage range, V_{DD5} (see Note 1)	– 0.3 V to 7 V
Input voltage range	– 0.3 V to 4.6 V
Output voltage range, 'LC206	– 0.3 V to 4.6 V
Output voltage range, 'C206	– 0.3 V to 7 V
Operating free-air temperature range, T_A (TMS320C206PZ, TMS320LC206PZ)	0°C to 70°C
(TMS320C206PZA, TMS320LC206PZA)	– 40°C to 85°C
Storage temperature range, T_{stg}	– 55°C to 150°C

† Stresses beyond those listed under “absolute maximum ratings” may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under “recommended operating conditions” is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

NOTE 1: All voltage values are with respect to V_{SS} .

recommended operating conditions‡

			MIN	NOM	MAX	UNIT

PARAMETER MEASUREMENT INFORMATION

Where: I_{OL} = 2 mA (all outputs)
 I_{OH} = 300 μ A (all outputs)
 V_{LOAD} = 1.5 V
 C_T = 40-pF typical load-circuit capacitance

Figure 6. Test Load Circuit

PARAMETER MEASUREMENT INFORMATION

signal-transition levels

The data in this section is shown for the 3.3-V and 5-V versions of the 'x20x. Note that some of the signals use different reference voltages, see the recommended operating conditions table. TTL-output levels are driven to a minimum logic-high level of 2.4 V and to a maximum logic-low level of 0.6 V.

Figure 7 shows the TTL-level outputs.

Figure 7. TTL-Level Outputs

TTL-output transition times are specified as follows:

- For a *high-to-low transition*, the level at which the output is said to be no longer high is below 80% of the total voltage range and lower and the level at which the output is said to be low is 20% of the total voltage range and lower.
- For a *low-to-high transition*, the level at which the output is said to be no longer low is 20% of the total voltage range and higher and the level at which the output is said to be high is 80% of the total voltage range and higher.

Figure 8 shows the TTL-level inputs.

Figure 8. TTL-Level Inputs

TTL-compatible input transition times are specified as follows:

- For a *high-to-low transition* on an input signal, the level at which the input is said to be no longer high is 90% of the total voltage range and lower and the level at which the input is said to be low is 10% of the total voltage range and lower.
- For a *low-to-high transition* on an input signal, the level at which the input is said to be no longer low is 10% of the total voltage range and higher and the level at which the input is said to be high is 90% of the total voltage range and higher.

PARAMETER MEASUREMENT INFORMATION

timing parameter symbology

Timing parameter symbols used are created in accordance with JEDEC Standard 100-A. To shorten the symbols, some of the pin names and other related terminology have been abbreviated as follows:

A	Address or A[15:0]	M	Address, data, and control signals: (A, D, MS, S, \overline{BR} , RD, W, and R/W)
CI	CLKIN/X2	MS	Memory strobe pins \overline{IS} , \overline{DS} , or \overline{PS}
CLKR	Serial-port receive clock	R	READY
CLKX	Serial-port transmit clock	RD	Read cycle or \overline{RD}
CO	CLKOUT1	RS	RESET pins RS or \overline{RS}
D	Data or D[15:0]	S	\overline{STRB} or synchronous
FR	FSR	TP	Transitory phase
FX	FSX	W	Write cycle or \overline{WE}
H	\overline{HOLD}		
HA	\overline{HOLDA}		
IN	INTN: \overline{BIO} , $\overline{INT1}$ – $\overline{INT3}$, \overline{NMI}		
IO	IOx: IO0, IO1, IO2, or IO3		

Lowercase subscripts and their meanings are:

a	access time
c	cycle time (period)
d	delay time
dis	disable time
en	enable time
f	fall time
h	hold time
r	rise time
su	setup time
t	transition time
v	valid time
w	pulse duration (width)

The following letters and symbols and their meanings are:

H	High
L	Low
IV	Invalid
HZ	High impedance
X	Unknown, changing, or don't care level

general notes on timing parameters

All output signals from the TMS320x206 devices (including CLKOUT1) are specified from an internal clock such that all output transitions for a given half cycle occur with a minimum of skewing relative to each other.

The signal combinations shown in the following timing diagrams may not necessarily represent actual cycles. For actual cycle examples, refer to the appropriate cycle description section of this data sheet.

CLOCK CHARACTERISTICS AND TIMING

clock options

PARAMETER	DIV2	DIV1
Internal divide-by-two with external crystal or external oscillator	0	0
PLL multiply-by-one	0	1
PLL multiply-by-two	1	0
PLL multiply-by-four	1	1

internal divide-by-two clock option with external crystal†

The internal oscillator is enabled by connecting a crystal across X1 and CLKIN/X2. The crystal should be in either fundamental or overtone operation and parallel resonant, with an effective series resistance of 30 Ω and a power dissipation of 1 mW; it should be specified at a load capacitance of 20 pF. Note that overtone crystals require an additional tuned-LC circuit. Figure 9 shows an external crystal (fundamental frequency) connected to the on-chip oscillator.

NOTE A: Texas Instruments encourages customers to submit samples of the device to the resonator/crystal vendor for full characterization.

Figure 9. Internal Clock Option

† PLL modes can also be used with the on-chip oscillator. However, in this case, the PLL lock time should be based on stable clock from the on-chip oscillator.

timing at $V_{DD} = 3.3 \text{ V}/5 \text{ V}$ with the PLL circuit disabled, divide-by-two mode ('C206, 'LC206)[†]

PARAMETER	TEST CONDITIONS	MIN	NOM	MAX	UNIT
f_x Input clock frequency	$T_A = -40^\circ\text{C to } 85^\circ\text{C}, 3.3 \text{ V}/5 \text{ V}$	0 [†]		80.0	MHz

[†] This device is implemented in static logic and therefore can operate with $t_{c(CI)}$ approaching ∞ . The device is characterized at 340 ns cycle.

switching characteristics over recommended operating conditions [$H = 0.5t_{c(CO)}$] (see Figure 10)

[†] INTN: \overline{BIO} , $\overline{INT1}$ – $\overline{INT3}$, \overline{NMI}

[‡] This parameter assumes the CLKIN to be stable before \overline{RS} goes active.

XF, TOUT, $\overline{\text{RS}}$, $\overline{\text{INT1}} - \overline{\text{INT3}}$, $\overline{\text{NMI}}$, and $\overline{\text{BIO}}$ timing (continued)

Case A. $\overline{\text{RS}}$ and $\overline{\text{PLLRS}}$ Activated at the Same Time During Power-on Reset

Case B. $\overline{\text{PLLRS}}$ Always Tied Low

Case C. Core Reset After Power Up, With $\overline{\text{PLLRS}}$ Tied High

† The value of x depends on the reset condition as follows:

Divide-by-two Mode: In this mode, the PLL is bypassed. Assuming CLKIN is stable, $x=0$. If the internal oscillator is used (i.e. a crystal is connected to X1 and X2 pins), x =oscillator lock-up time. The state of the $\overline{\text{PLLRS}}$ is not applicable for $\div 2$ mode and should always be tied high or low.

PLL enabled: Assuming CLKIN is stable, x =PLL lock-up time. If the internal oscillator is used, x =oscillator lock-up time + PLL lock-up time. In case of resets after power on reset, $x=0$, i.e. $t_{w(RSL)}=12\text{ H ns}$ only.

Figure 16. Reset Timings: Cases A, B, and C

‡ INTN: $\overline{\text{BIO}}$, $\overline{\text{INT1}} - \overline{\text{INT3}}$, $\overline{\text{NMI}}$

PLASTIC QUAD FLATPACK

- NOTES: A. All linear dimensions are in millimeters.
B. This drawing is subject to change without notice.
C. Falls within JEDEC MO-136

Thermal Resistance Characteristics

PARAMETER	DESCRIPTION	°C/W
Θ_{JA}	Junction-to-ambient	58
Θ_{JC}	Junction-to-case	10

IMPORTANT NOTICE

Texas Instruments and its subsidiaries (TI) reserve the right to make changes to their products or to discontinue any product or service without notice, and advise customers to obtain the latest version of relevant information to verify, before placing orders, that information being relied on is current and complete. All products are sold subject to the terms and conditions of sale supplied at the time of order acknowledgement, including those pertaining to warranty, patent infringement, and limitation of liability.

TI warrants performance of its semiconductor products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are utilized to the extent TI deems necessary to support this warranty. Specific testing of all parameters of each device is not necessarily performed, except those mandated by government requirements.

CERTAIN APPLICATIONS USING SEMICONDUCTOR PRODUCTS MAY INVOLVE POTENTIAL RISKS OF DEATH, PERSONAL INJURY, OR SEVERE PROPERTY OR ENVIRONMENTAL DAMAGE ("CRITICAL APPLICATIONS"). TI SEMICONDUCTOR PRODUCTS ARE NOT DESIGNED, AUTHORIZED, OR WARRANTED TO BE SUITABLE FOR USE IN LIFE-SUPPORT DEVICES OR SYSTEMS OR OTHER CRITICAL APPLICATIONS. INCLUSION OF TI PRODUCTS IN SUCH APPLICATIONS IS UNDERSTOOD TO BE FULLY AT THE CUSTOMER'S RISK.

In order to minimize risks associated with the customer's applications, adequate design and operating safeguards must be provided by the customer to minimize inherent or procedural hazards.

TI assumes no liability for applications assistance or customer product design. TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right of TI covering or relating to any combination, machine, or process in which such semiconductor products or services might be or are used. TI's publication of information regarding any third party's products or services does not constitute TI's approval, warranty or endorsement thereof.

Компания «Океан Электроники» предлагает заключение долгосрочных отношений при поставках импортных электронных компонентов на взаимовыгодных условиях!

Наши преимущества:

- Поставка оригинальных импортных электронных компонентов напрямую с производств Америки, Европы и Азии, а так же с крупнейших складов мира;
- Широкая линейка поставок активных и пассивных импортных электронных компонентов (более 30 млн. наименований);
- Поставка сложных, дефицитных, либо снятых с производства позиций;
- Оперативные сроки поставки под заказ (от 5 рабочих дней);
- Экспресс доставка в любую точку России;
- Помощь Конструкторского Отдела и консультации квалифицированных инженеров;
- Техническая поддержка проекта, помощь в подборе аналогов, поставка прототипов;
- Поставка электронных компонентов под контролем ВП;
- Система менеджмента качества сертифицирована по Международному стандарту ISO 9001;
- При необходимости вся продукция военного и аэрокосмического назначения проходит испытания и сертификацию в лаборатории (по согласованию с заказчиком);
- Поставка специализированных компонентов военного и аэрокосмического уровня качества (Xilinx, Altera, Analog Devices, Intersil, Interpoint, Microsemi, Actel, Aeroflex, Peregrine, VPT, Syfer, Eurofarad, Texas Instruments, MS Kennedy, Miteq, Cobham, E2V, MA-COM, Hittite, Mini-Circuits, General Dynamics и др.);

Компания «Океан Электроники» является официальным дистрибьютором и эксклюзивным представителем в России одного из крупнейших производителей разъемов военного и аэрокосмического назначения «JONHON», а так же официальным дистрибьютором и эксклюзивным представителем в России производителя высокотехнологичных и надежных решений для передачи СВЧ сигналов «FORSTAR».

JONHON

«JONHON» (основан в 1970 г.)

Разъемы специального, военного и аэрокосмического назначения:

(Применяются в военной, авиационной, аэрокосмической, морской, железнодорожной, горно- и нефтедобывающей отраслях промышленности)

«FORSTAR» (основан в 1998 г.)

ВЧ соединители, коаксиальные кабели,
кабельные сборки и микроволновые компоненты:

(Применяются в телекоммуникациях гражданского и специального назначения, в средствах связи, РЛС, а так же военной, авиационной и аэрокосмической отраслях промышленности).
