![ANALOG DEVICES]

14-Bit, 3 GSPS, JESD204B, Dual Analog-to-Digital Converter

Data Sheet

AD9208

FEATURES

JESD204B (Subclass 1) coded serial digital outputs
   Support for lane rates up to 16 Gbps per lane
1.65 W total power per channel at 3 GSPS (default settings)
Performance at −2 dBFS amplitude, 2.6 GHz input
   SFDR = 70 dBFS
   SNR = 57.2 dBFS
Performance at −9 dBFS amplitude, 2.6 GHz input
   SFDR = 78 dBFS
   SNR = 59.5 dBFS
Integrated input buffer
Noise density = −152 dBFS/Hz
0.975 V, 1.9 V, and 2.5 V dc supply operation
9 GHz analog input full power bandwidth (−3 dB)
Amplitude detect bits for efficient AGC implementation
2 integrated, wideband digital processors per channel
   48-bit NCO
   4 cascaded half-band filters
Phase coherent NCO switching
Up to 4 channels available
Serial port control
   Integer clock with divide by 2 and divide by 4 options
   Flexible JESD204B lane configurations
On-chip dither

APPLICATIONS

Diversity multiband and multimode digital receivers
3G/4G, TD-SCDMA, W-CDMA, and GSM, LTE, LTE-A
Electronic test and measurement systems
Phased array radar and electronic warfare
DOCSIS 3.0 CMTS upstream receive paths
HFC digital reverse path receivers

REVISION HISTORY

4/2017—Revision 0: Initial Version

GENERAL DESCRIPTION

The AD9208 is a dual, 14-bit, 3 GSPS analog-to-digital converter (ADC). The device has an on-chip buffer and a sample-and-hold circuit designed for low power, small size, and ease of use. This product is designed to support communications applications capable of direct sampling wide bandwidth analog signals of up to 5 GHz. The −3 dB bandwidth of the ADC input is 9 GHz. The AD9208 is optimized for wide input bandwidth, high sampling rate, excellent linearity, and low power in a small package.

The dual ADC cores feature a multistage, differential pipelined architecture with integrated output error correction logic. Each ADC features wide bandwidth inputs supporting a variety of user-selectable input ranges. An integrated voltage reference eases design considerations. The analog input and clock signals are differential inputs. The ADC data outputs are internally connected to four digital downconverters (DDCs) through a crossbar mux. Each DDC consists of up to five cascaded signal processing stages: a 48-bit frequency translator (numerically controlled oscillator (NCO)), and up to four half-band decimation filters. The NCO has the option to select preset bands over the general-purpose input/output (GPIO) pins, which enables the selection of up to three bands. Operation of the AD9208 between the DDC modes is selectable via SPI-programmable profiles.

In addition to the DDC blocks, the AD9208 has several functions that simplify the automatic gain control (AGC) function in a communications receiver. The programmable threshold detector allows monitoring of the incoming signal power using the fast detect control bits in Register 0x0245 of the ADC. If the input signal level exceeds the programmable threshold, the fast detect indicator goes high. Because this threshold indicator has low latency, the user can quickly turn down the system gain to avoid an overrange condition at the ADC input. In addition to the fast detect outputs, the AD9208 also offers signal monitoring

capability. The signal monitoring block provides additional information about the signal being digitized by the ADC.

The user can configure the Subclasss 1 JESD204B-based high speed serialized output in a variety of one-lane, two-lane, four-lane, and eight-lane configurations, depending on the DDC configuration and the acceptable lane rate of the receiving logic device. Multidevice synchronization is supported through the SYSREF± and SYNCINB± input pins.

The AD9208 has flexible power-down options that allow significant power savings when desired. All of these features can be programmed using a 3-wire serial port interface (SPI).

The AD9208 is available in a Pb-free, 196-ball BGA, specified over the −40°C to +85°C ambient temperature range. This product is protected by a U.S. patent.

Note that throughout this data sheet, multifunction pins, such as FD_A/GPIO_A0, are referred to either by the entire pin name or by a single function of the pin, for example, FD_A, when only that function is relevant.

PRODUCT HIGHLIGHTS

1. Wide, input −3 dB bandwidth of 9 GHz supports direct radio frequency (RF) sampling of signals up to about 5 GHz.
2. Four integrated, wideband decimation filter and NCO blocks supporting multiband receivers.
3. Fast NCO switching enabled through the GPIO pins.
4. A SPI controls various product features and functions to meet specific system requirements.
5. Programmable fast overrange detection and signal monitoring.
6. On-chip temperature diode for system thermal management.
7. 12 mm × 12 mm, 196-ball BGA.

SPECIFICATIONS

DC SPECIFICATIONS

AVDD1 = 0.975 V, AVDD1_SR = 0.975 V, AVDD2 = 1.9 V, AVDD3 = 2.5 V, DVDD = 0.975 V, DRVDD1 = 0.975 V, DRVDD2 = 1.9 V, SPIVDD = 1.9 V, specified maximum sampling rate, 1.7 V p-p full-scale differential input, input amplitude (A_{IN}) = −2.0 dBFS, L = 8, M = 2, F = 1, −10°C ≤ T_J ≤ +120°C,[1] unless otherwise noted. Typical specifications represent performance at T_J = 70°C (T_A = 25°C).

Table 1.

Parameter	Min	Typ	Max	Unit
RESOLUTION	14			Bits
ACCURACY				
No Missing Codes		Guaranteed		
Offset Error		0		%FSR
Offset Matching		0		%FSR
Gain Error	−5.89	±1	+5.89	%FSR

Common-Mode Voltage(V_{CM})	1.32	1.35	1.52	V
Differential Input Resistance		200		Ω
Differential Input Capacitance		0.25		pF
Differential Input Return Loss at 2.1 GHz[2]		−7		dB
−3 dB Bandwidth		9		GHz
POWER SUPPLY				
AVDD1	0.95	0.975	1.0	V
AVDD2	1.85	1.9	1.95	V
AVDD3	2.44	2.5	2.56	V
AVDD1_SR	0.95	0.975	1.0	V
DVDD	0.95	0.975	1.0	V
DRVDD1	0.95	0.975	1.0	V
DRVDD2	1.85	1.9	1.95	V
SPIVDD	1.85	1.9	1.95	V
I_{AVDD1}		640	765	mA
I_{AVDD2}		790	885	mA
I_{AVDD3}		110	120	mA
I_{AVDD1_SR}		24	50	mA
I_{DVDD}		480	1020	mA
I_{DRVDD1}[3]		320	590	mA
I_{DRVDD2}		30	35	mA
I_{SPIVDD}		1	5	mA
POWER CONSUMPTION				
Total Power Dissipation (Including Output Drivers)[4]		3.3		W
Power-Down Dissipation		300		mW
Standby[5]		1.65		mW

[1] The junction temperature (T_J) range of −10°C to +120°C translates to an ambient temperature (T_A) range of −40°C to +85°C.
[2] For more information, see the Analog Input Considerations section.
[3] All lanes running. Power dissipation on DRVDD1 changes with lane rate and number of lanes used.
[4] Default mode. No DDCs used.
[5] Can be controlled by the SPI.

AC SPECIFICATIONS

AVDD1 = 0.975 V, AVDD1_SR = 0.975 V, AVDD2 = 1.9 V, AVDD3 = 2.5 V, DVDD = 0.975 V, DRVDD1 = 0.975 V, DRVDD2 = 1.9 V, SPIVDD = 1.9 V, specified maximum sampling rate, 1.7 V p-p full-scale differential input, default SPI settings, −10°C ≤ T_J ≤ +120°C,[1] unless otherwise noted. Typical specifications represent performance at T_J = 70°C (T_A = 25°C).

Table 2.

f_{IN1} = 2.62 GHz, f_{IN2} = 2.69 GHz, A_{IN1} and A_{IN2} = −15.0 dBFS; V_{FS} = 1.13 V p-p					−111		dBFS
CROSSTALK[4]		>90			>90		dB
Overrange Condition[5]		>90			>90		dB
ANALOG INPUT BANDWIDTH, FULL POWER[6]		5			5		GHz

[1] The junction temperature (T_J) range of −10°C to +120°C translates to an ambient temperature (T_A) range of −40°C to+ 85°C.
[2] See the AN-835 Application Note, *Understanding High Speed ADC Testing and Evaluation*, for definitions and for details on how these tests were completed.
[3] Noise density is measured at a low analog input frequency (30 MHz).
[4] Crosstalk is measured at 950 MHz with a −1.0 dBFS analog input on one channel, and no input on the adjacent channel.
[5] The overrange condition is specified with 3 dB of the full-scale input range.
[6] Full power bandwidth is the bandwidth of operation in which proper ADC performance can be achieved.

DIGITAL SPECIFICATIONS

AVDD1 = 0.975 V, AVDD1_SR = 0.975 V, AVDD2 = 1.9 V, AVDD3 = 2.5 V, DVDD = 0.975 V, DRVDD1 = 0.975 V, DRVDD2 = 1.9 V, SPIVDD = 1.9 V, specified maximum sampling rate, 1.7 V p-p full-scale differential input, A_{IN} = −2.0 dBFS, L = 8, M = 2, F = 1, −10°C ≤ T_J ≤ +120°C,[1] unless otherwise noted. Typical specifications represent performance at T_J = 70°C (T_A = 25°C).

Table 3.

Parameter	Min	Typ	Max	Unit
CLOCK INPUTS (CLK+, CLK−)				
Logic Compliance		LVDS/LVPECL		
Differential Input Voltage	300	800	1800	mV p-p
Input Common-Mode Voltage		0.675		V

Logic Compliance		LVDS/LVPECL		
Differential Input Voltage	400	800	1800	mV p-p
Input Common-Mode Voltage		0.675	2.0	V
Input Resistance (Differential)		18		kΩ
Input Capacitance		1		pF
SYNCINB+ INPUT				
Logic Compliance		CMOS		
Logic 1 Voltage	0.9 × DRVDD1		2 × DRVDD1	V
Logic 0 Voltage			0.1 × DRVDD1	V
Input Resistance		2.6		kΩ
DIGITAL OUTPUTS (SERDOUTx±, x = 0 TO 7)				
Logic Compliance		SST		
Differential Output Voltage	360	560	770	mV p-p
Differential Termination Impedance	80	100	120	Ω

[1] The junction temperature (T_J) range of −10°C to +120°C translates to an ambient temperature (T_A) range of −40°C to+85°C.
[2] Reference impedance = 100 Ω.

SWITCHING SPECIFICATIONS

AVDD1 = 0.975 V, AVDD1_SR = 0.975 V, AVDD2 = 1.9 V, AVDD3 = 2.5 V, DVDD = 0.975 V, DRVDD1 = 0.975 V, DRVDD2 = 1.9 V, SPIVDD = 1.9 V, specified maximum sampling rate, 1.7 V p-p full-scale differential input, A_{IN} = −2.0 dBFS, default SPI settings, −10°C ≤ T_J ≤ +120°C,[1] unless otherwise noted. Typical specifications represent performance at T_J = 70°C (T_A = 25°C).

Table 4.

Parameter	Min	Typ	Max	Unit
CLOCK				
Clock Rate (at CLK+/CLK− Pins)		3	6	GHz
Sample Rate[2]	2500	3000	3100	MSPS
Clock Pulse Width High	161.29	166.67	192.31	ps
Clock Pulse Width Low	161.29	166.67	192.31	ps
OUTPUT PARAMETERS				
Unit Interval (UI)[3]	62.5	66.67	592.6	ps
Rise Time (t_R) (20% to 80% into 100 Ω Load)		26		ps
Fall Time (t_F) (20% to 80% into 100 Ω Load)		26		ps
Phase-Locked Loop (PLL) Lock Time		5		ms
Data Rate per Channel (Nonreturn to Zero)[4]	1.6875	15	16	Gbps
LATENCY[5]				
Pipeline Latency[6]		75		Clock cycles
Fast Detect Latency		26		Clock cycles
WAKE-UP TIME				
Standby		400		µs
Power-Down		15		ms
NCO CHANNEL SELECTION TO OUTPUT			8	Clock cycles
APERTURE				
Aperture Delay (t_A)		250		ps
Aperture Uncertainty (Jitter, t_J)		55		fs rms
Out of Range Recovery Time		1		Clock cycles

[1] The junction temperature (T_J) range of −10°C to +120°C translates to an ambient temperature (T_A) range of −40°C to +85°C.
[2] The maximum sample rate is the clock rate after the divider.
[3] Baud rate = 1/UI. A subset of this range can be supported.
[4] Default L = 8. This number can be changed based on the sample rate and decimation ratio.
[5] No DDCs used. L = 8, M = 2, and F = 1.
[6] Refer to the Latency section for more details.

TIMING SPECIFICATIONS

Table 5.

Parameter	Description	Min	Typ	Max	Unit
CLK+ to SYSREF+ TIMING REQUIREMENTS					
t_{SU_SR}	Device clock to SYSREF+ setup time		−65		ps
t_{H_SR}	Device clock to SYSREF+ hold time		95		ps
SPI TIMING REQUIREMENTS					
t_{DS}	Setup time between the data and the rising edge of SCLK	2			ns
t_{DH}	Hold time between the data and the rising edge of SCLK	2			ns
t_{CLK}	Period of the SCLK	40			ns
t_S	Setup time between CSB and SCLK	2			ns
t_H	Hold time between CSB and SCLK	2			ns
t_{HIGH}	Minimum period that SCLK must be in a logic high state	10			ns
t_{LOW}	Minimum period that SCLK must be in a logic low state	10			ns
t_{ACCESS}	Maximum time delay between the falling edge of SCLK and output data valid for a read operation		6	10	ns
t_{DIS_SDIO}	Time required for the SDIO pin to switch from an output to an input, relative to the SCLK rising edge (not shown in Figure 4)	10			ns

ABSOLUTE MAXIMUM RATINGS

Table 6.

Parameter	Rating
Electrical	
AVDD1 to AGND	1.05 V
AVDD1_SR to AGND	1.05 V
AVDD2 to AGND	2.0 V
AVDD3 to AGND	2.70 V
DVDD to DGND	1.05 V
DRVDD1 to DRGND	1.05 V
DRVDD2 to DRGND	2.0 V
SPIVDD to DGND	2.0 V
AGND to DRGND	−0.3 V to +0.3 V
AGND to DGND	−0.3 V to +0.3 V
DGND to DRGND	−0.3 V to +0.3 V
VIN±x to AGND	AGND − 0.3 V to AVDD3 + 0.3 V
CLK± to AGND	AGND − 0.3 V to AVDD1 + 0.3 V
SCLK, SDIO, CSB to DGND	DGND − 0.3 V to SPIVDD + 0.3 V
PDWN/STBY to DGND	DGND − 0.3 V to SPIVDD + 0.3 V
SYSREF± to AGND	2.5 V
SYNCINB± to DRGND	2.5 V
Junction Temperature Range (T_J)	−40°C to +125°C
Storage Temperature Range, Ambient (T_A)	−65°C to +150°C

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

THERMAL RESISTANCE

Thermal performance is directly linked to printed circuit board (PCB) design and operating environment. Close attention to PCB thermal design is required. $θ_{JA}$ is the natural convection junction-to-ambient thermal resistance measured in a one cubic foot sealed enclosure. $θ_{JC}$ is the junction to case thermal resistance.

Table 7. Thermal Resistance

Package Type	$θ_{JA}$	$θ_{JC\_TOP}$	$Ψ_{JB}$	$Ψ_{JT}$	Unit
BP-196-4[1]	16.26	1.4	5.44	1.68	°C/W

[1] Test Condition 1: Thermal impedance simulated values are based on JEDEC 2S2P thermal test board with 190 thermal vias. See JEDEC JESD51.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

Table 8. Pin Function Descriptions[1]

Pin No.	Mnemonic	Type	Description
Power Supplies			
A3, A12, B3, B12, C3, C12	AVDD1	Power	Analog Power Supply (0.975 V Nominal).
A4, A5, A10, A11, B4, B11	AVDD1[2]	Power	Analog Power Supply for the Clock Domain (0.975 V Nominal).
A1, A2, A13, A14, B1, B2, B13, B14, C1, C2, C13, C14	AVDD2	Power	Analog Power Supply (1.9 V Nominal).
D1, D14, G1, G14	AVDD3	Power	Analog Power Supply (2.5 V Nominal).
E7	AVDD1_SR	Power	Analog Power Supply for SYSREF± (0.975 V Nominal).
L3, L10	SPIVDD	Power	Digital Power Supply for SPI (1.9 V Nominal).
M14, N1, N2, N14, P1, P2, P14	DVDD	Power	Digital Power Supply (0.975 V Nominal).
M5 to M8, M11	DRVDD1	Power	Digital Driver Power Supply (0.975 V Nominal).
M13	DRVDD2	Power	Digital Driver Power Supply (1.9 V Nominal).
B5, B10, C4, C5, C10, C11, D2 to D6, D9 to D13, E2 to E5, E9 to E13, F2 to F6, F9 to F13, G2 to G13, H1 to H9, H11 to H14, J1 to J14	AGND	Ground	Analog Ground. These pins connect to the analog ground plane.
A6, A9, B6 to B9, C6 to C9, D7, D8	AGND[2]	Ground	Ground Reference for the Clock Domain.
E6, E8	AGND[3]	Ground	Ground Reference for SYSREF±.
K1 to K14	AGND[4]	Ground	Isolation Ground.
L1, L12 to L14, M1, M2	DGND	Ground	Digital Control Ground Supply. These pins connect to the digital ground plane.
M3, M4, M9, M10, M12, N3, N12, P3, P12	DRGND	Ground	Digital Driver Ground Supply. These pins connect to the digital driver ground plane.
Analog			
E1, F1	VIN−B, VIN+B	Input	ADC B Analog Input Complement/True.
E14, F14	VIN−A, VIN+A	Input	ADC A Analog Input Complement/True.
A7, A8	CLK+, CLK−	Input	Clock Input True/Complement.
H10	VREF	Input/DNC	0.50 V Reference Voltage Input/Do Not Connect. This pin is configurable through the SPI as a no connect or an input. Do not connect this pin if using the internal reference. This pin requires a 0.50 V reference voltage input if using an external voltage reference source.
CMOS Inputs/Outputs			
L2	GPIO_B1	Input/output	GPIO B1.
L4	FD_B/GPIO_B0	Input/output	Fast Detect Outputs for Channel B/GPIO B0.
L9	FD_A/GPIO_A0	Input/output	Fast Detect Outputs for Channel A/GPIO A0.
L11	GPIO_A1	Input/output	GPIO A1.
Digital Inputs			
F7, F8	SYSREF+, SYSREF−	Input	Active High JESD204B LVDS System Reference Input True/Complement.
N13	SYNCINB+	Input	Active Low JESD204B LVDS/CMOS Sync Input True.
P13	SYNCINB−	Input	Active Low JESD204B LVDS Sync Input Complement.
Data Outputs			
N4, P4	SERDOUT7+, SERDOUT7−	Output	Lane 7 Output Data True/Complement.
N5, P5	SERDOUT6+, SERDOUT6−	Output	Lane 6 Output Data True/Complement.
N6, P6	SERDOUT5+, SERDOUT5−	Output	Lane 5 Output Data True/Complement.
N7, P7	SERDOUT4+, SERDOUT4−	Output	Lane 4 Output Data True/Complement.
N8, P8	SERDOUT3+, SERDOUT3−	Output	Lane 3 Output Data True/Complement.
N9, P9	SERDOUT2+, SERDOUT2−	Output	Lane 2 Output Data True/Complement.
N10, P10	SERDOUT1+, SERDOUT1−	Output	Lane 1 Output Data True/Complement.
N11, P11	SERDOUT0+, SERDOUT0−	Output	Lane 0 Output Data True/Complement.

Pin No.	Mnemonic	Type	Description
Digital Controls			
L8	PDWN/STBY	Input	Power-Down Input (Active High). The operation of this pin depends on the SPI mode and can be configured as power-down or standby.
L5	CSB	Input	SPI Chip Select (Active Low).
L6	SCLK	Input	SPI Serial Clock.
L7	SDIO	Input/output	SPI Serial Data Input/Output.

[1] See the Theory of Operation section and the Applications Information section for more information on isolating the planes for optimal performance.
[2] Denotes clock domain.
[3] Denotes SYSREF± domain.
[4] Denotes isolation domain.

TYPICAL PERFORMANCE CHARACTERISTICS

AVDD1 = 0.975 V, AVDD1_SR = 0.975 V, AVDD2 = 1.9 V, AVDD3 = 2.5 V, DVDD = 0.975 V, DRVDD1 = 0.975 V, DRVDD2 = 1.9 V, SPIVDD = 1.9 V, sampling rate = 3000 MHz, 1.7 V p-p full-scale differential input, DDC decimation rate = 8, default buffer current settings, T_A = 25°C, 128,000 fast Fourier transform (FFT) sample, unless otherwise noted. See Table 10 for the recommended settings.

THEORY OF OPERATION

The AD9208 has two analog input channels and up to eight JESD204B output lane pairs. The ADC samples wide bandwidth analog signals of up to 5 GHz. The actual −3 dB roll-off of the analog inputs is 9 GHz. The AD9208 is optimized for wide input bandwidth, high sampling rate, excellent linearity, and low power in a small package.

The dual ADC cores feature a multistage, differential pipelined architecture with integrated output error correction logic. Each ADC features wide bandwidth inputs supporting a variety of user-selectable input ranges. An integrated voltage reference eases design considerations.

The AD9208 has several functions that simplify the AGC function in a communications receiver. The programmable threshold detector allows monitoring of the incoming signal power using the fast detect output bits of the ADC. If the input signal level exceeds the programmable threshold, the fast detect indicator goes high. Because this threshold indicator has low latency, the user can quickly turn down the system gain to avoid an overrange condition at the ADC input.

The Subclass 1 JESD204B-based high speed serialized output data lanes can be configured in one-lane (L = 1), two-lane (L = 2), four-lane (L = 4), and eight-lane (L = 8) configurations, depending on the sample rate and the decimation ratio. Multiple device synchronization is supported through the SYSREF± and SYNCINB± input pins. The SYSREF± pin in the AD9208 can also be used as a timestamp of data as it passes through the ADC and out of the JESD204B interface.

ADC ARCHITECTURE

The architecture of the AD9208 consists of an input buffered pipelined ADC. The input buffer provides a termination impedance to the analog input signal. This termination impedance is set to 200 Ω. The equivalent circuit diagram of the analog input termination is shown in Figure 29. The input buffer is optimized for high linearity, low noise, and low power across a wide bandwidth.

The input buffer provides a linear high input impedance (for ease of drive) and reduces kickback from the ADC. The quantized outputs from each stage are combined into a final 14-bit result in the digital correction logic. The pipelined architecture permits the first stage to operate with a new input sample; at the same time, the remaining stages operate with the preceding samples. Sampling occurs on the rising edge of the clock.

ANALOG INPUT CONSIDERATIONS

The analog input to the AD9208 is a differential buffer. The internal common-mode voltage of the buffer is 1.35 V. The clock signal alternately switches the input circuit between sample mode and hold mode.

Either a differential capacitor or two single-ended capacitors (or a combination of both) can be placed on the inputs to provide a matching passive network. These capacitors ultimately create a low-pass filter that limits unwanted broadband noise. For more information, refer to the *Analog Dialogue* article "Transformer-Coupled Front-End for Wideband A/D Converters" (Volume 39, April 2005). In general, the precise front-end network component values depend on the application.

Figure 53 shows the differential input return loss curve for the analog inputs across a frequency range of 100 MHz to 10 GHz. The reference impedance is 100 Ω.

m1
FREQUENCY = 100MHz
SDD11 = 0.301/−8.069

IMPEDANCE = Z0 × (0.379 − j0.347)

m5
FREQUENCY = 5GHz
SDD11 = 0.475/79.360
IMPEDANCE= Z0 × (0.737 − j0.889)
Figure 53. Differential Input Return Loss

For best dynamic performance, the source impedances driving VIN+x and VIN−x must be matched such that common-mode settling errors are symmetrical. These errors are reduced by the common-mode rejection of the ADC. An internal reference buffer creates a differential reference that defines the span of the ADC core.

Maximum SNR performance is achieved by setting the ADC to the largest span in a differential configuration. For the AD9208, the available span is programmable through the SPI port from 1.13 V p-p to 2.04 V p-p differential, with 1.7 V p-p differential being the default.

Differential Input Configurations

There are several ways to drive the AD9208, either actively or passively. Optimum performance is achieved by driving the analog input differentially.

For applications where SNR and SFDR are key parameters, differential transformer coupling is the recommended input configuration (see Figure 54 and Table 9) because the noise performance of most amplifiers is not adequate to achieve the true performance of the AD9208.

For low to midrange frequencies, a double balun or double transformer network (see Figure 54 and Table 9) is recommended for optimum performance of the AD9208. For higher frequencies

in the second or third Nyquist zones, it is recommended to remove some of the front-end passive components to ensure wideband operation (see Figure 55 and Table 9).
NOTES:
1. SEE TABLE 9 FOR COMPONENT VALUES

Figure 54. Differential Transformer Coupled Configuration for the AD9208
Figure 55. Input Network Configuration for Frequencies > 5 GHz

Table 9. Differential Transformer-Coupled Input Configuration Component Values

Frequency Range	Transformer	R1	R2	R3	C1	C2	C3	C4
<5000 MHz	BAL-0006	25 Ω	25 Ω	10 Ω	0.1 µF	0.1 µF	0.4 pF	0.4 pF

Input Common Mode

The analog inputs of the AD9208 are internally biased to the common-mode voltage, as shown in Figure 57. The common-mode buffer has a limited range in that the performance suffers greatly if the common-mode voltage drops by more than 50 mV on either side of the nominal value.

For dc-coupled applications, the recommended operation procedure is to export the common-mode voltage to the VREF pin using the SPI writes listed in this section. The common-mode voltage must be set by the exported value to ensure proper ADC operation. Disconnect the internal common-mode buffer from the analog input using Register 0x1908.

When performing SPI writes for dc coupling operation, use the following register settings in order:

8. Set Register 0x1908, Bit 2 to disconnect the internal common-mode buffer from the analog input. Note that this is a local register.
9. Set Register 0x18A6 to 0x00 to turn off the voltage reference.

10. Set Register 0x18E6 to 0x00 to turn off the temperature diode export.
11. Set Register 0x18E3, Bit 6 to 1 to turn on the V_{CM} export.
12. Set Register 0x18E3, Bits[5:0] to the buffer current setting (Register 0x1A4C and Register 0x1A4D) to improve the accuracy of the common-mode export.

Figure 56 shows the block diagram representation of a dc-coupled application.
Figure 56. DC-Coupled Application Using the AD9208

Analog Input Buffer Controls and SFDR Optimization
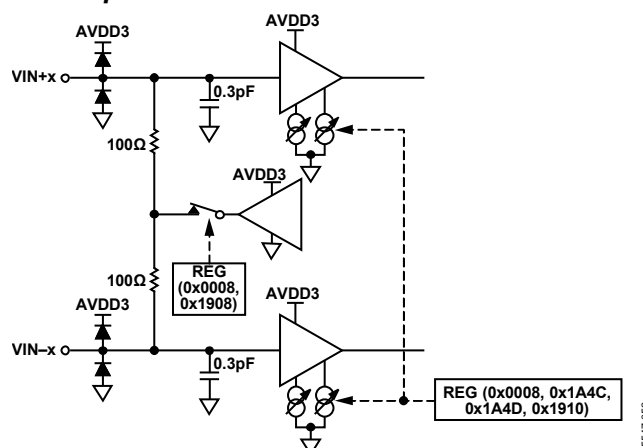

Figure 57. Analog Input Controls

The AD9208 input buffer offers flexible controls for the analog inputs, such as buffer current, dc coupling, and input full-scale adjustment. All the available controls are shown in Figure 57.

Using Register 0x1A4C and Register 0x1A4D, the buffer behavior on each channel can be adjusted to optimize the SFDR over various input frequencies and bandwidths of interest. Use Register 0x1910 to change the internal reference voltage. Changing the internal reference voltage results in a change in the input full-scale voltage.

When the input buffer current in Register 0x1A4C and Register 0x1A4D is set, the amount of current required by the AVDD3 supply changes. This relationship is shown in Figure 58. For a complete list of buffer current settings, see Table 46.
Figure 58. AVDD3 Current (I_{AVDD3}) vs. Buffer Current Setting (Buffer Control 1 Setting in Register 0x1A4C and Buffer Control 2 Setting in Register 0x1A4D)

Table 10 shows the recommended values for the buffer current for various Nyquist zones.

Table 10. SFDR Optimization for Input Frequencies

Frequency	Register 0x1A4C and Register 0x1A4D
DC to 1500 MHz	400 µA/500 µA
1500 MHz to 3000 MHz	500 µA
>3000 MHz	500 µA/700 µA

Dither

The AD9208 has internal on-chip dither circuitry that improves the ADC linearity and SFDR, particularly at smaller signal levels. A known but random amount of white noise is injected into the input of the AD9208. This dither improves the small signal linearity within the ADC transfer function and is precisely subtracted out digitally. The dither is turned on by default and does not reduce the ADC input dynamic range. The data sheet specifications and limits are obtained with the dither turned on.

The dither is on by default. It is not recommended to turn it off.

Absolute Maximum Input Swing

The absolute maximum input swing allowed at the inputs of the AD9208 is 5.8 V p-p differential. Signals operating near or at this level can cause permanent damage to the ADC. See Table 6 for more information.
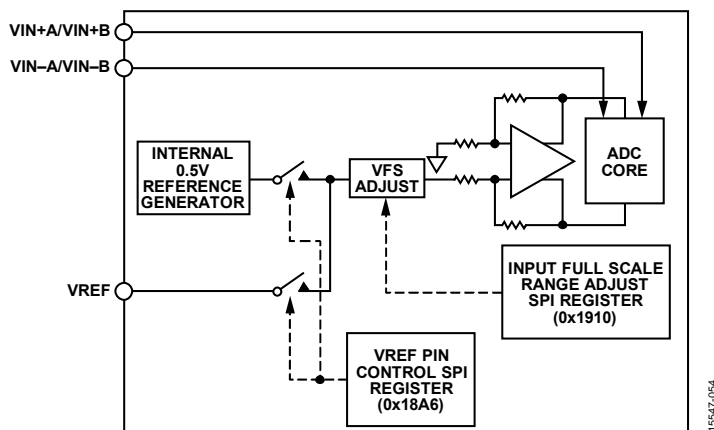

Figure 59. Internal Reference Configuration and Controls
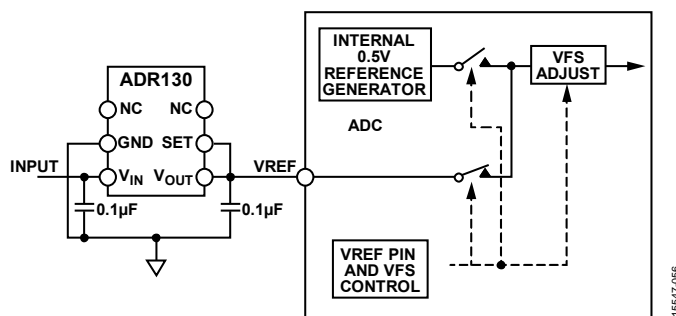

Figure 60. External Reference Using the ADR130

VOLTAGE REFERENCE

A stable and accurate 0.5 V voltage reference is built into the AD9208. This internal 0.5 V reference sets the full-scale input range of the ADC. The full-scale input range can be adjusted via the ADC input full-scale control register (Register 0x1910). For more information on adjusting the input swing, see Table 46. Figure 59 shows the block diagram of the internal 0.5 V reference controls.

The SPI Register 0x18A6 enables the user to either use this internal 0.5 V reference, or to provide an external 0.5 V reference. When using an external voltage reference, provide a 0.5 V reference. The full-scale adjustment is made using the SPI, irrespective of the reference voltage. For more information on adjusting the full-scale level of the AD9208, refer to the Memory Map section.

The SPI writes required to use the external voltage reference, in order, are as follows:

1. Set Register 0x18E3 to 0x00 to turn off the V_{CM} export.
2. Set Register 0x18E6 to 0x00 to turn off the temperature diode export.
3. Set Register 0x18A6 to 0x01 to turn on the external voltage reference.

The use of an external reference may be necessary, in some applications, to enhance the gain accuracy of the ADC or to improve thermal drift characteristics. Figure 61 shows the typical drift characteristics of the internal 0.5 V reference.
Figure 61. Typical V_{REF} Drift

The external reference must be a stable 0.5 V reference. The ADR130 is a sufficient option for providing the 0.5 V reference. Figure 60 shows how the ADR130 can be used to provide the external 0.5 V reference to the AD9208. The dashed lines show unused blocks within the AD9208 while using the ADR130 to provide the external reference.

DC OFFSET CALIBRATION

The AD9208 contains a digital filter to remove the dc offset from the output of the ADC. For ac-coupled applications, this filter can be enabled by writing 0x86 to Register 0x0701. The filter computes the average dc signal and it is digitally subtracted from the ADC output. As a result, the dc offset is improved to better than 70 dBFS at the output. Because the filter does not distinguish between the source of dc signals, this feature can be used when the signal content at dc is not of interest. The filter corrects dc up to ±512 codes and saturates beyond that.

CLOCK INPUT CONSIDERATIONS

For optimum performance, drive the AD9208 sample clock inputs (CLK+ and CLK−) with a differential signal. This signal is ac-coupled to the CLK+ and CLK− pins via a transformer or clock drivers. These pins are biased internally and require no additional biasing.

Figure 62 shows the differential input return loss curve for the clock inputs across a frequency range of 100 MHz to 6 GHz. The reference impedance is 100 Ω.

FREQUENCY (100MHz TO 6GHz)
m1
FREQUENCY = 2.503GHz
SDD11 = 0.313/−173.307
IMPEDANCE = Z0 × (0.524 − j0.042)

m2
FREQUENCY = 2.996GHz
SDD11 = 0.337/169.383
IMPEDANCE = Z0 × (0.499 − j0.070)

m3
FREQUENCY = 3.104GHz
SDD11 = 0.332/165.502
IMPEDANCE = Z0 × (0.508 − j0.095)

m4
FREQUENCY = 6GHz
SDD11 = 0.271/54.790
IMPEDANCE = Z0 × (1.218 − j0.581)

Figure 62. Differential Input Return Loss for the CLK± Inputs

Figure 63 shows a preferred method for clocking the AD9208. The low jitter clock source is converted from a single-ended signal to a differential signal using an RF transformer.
Figure 63. Transformer-Coupled Differential Clock

Another option is to ac couple a differential CML or LVPECL signal to the sample clock input pins, as shown in Figure 64 and Figure 65.
Figure 64. Differential LVPECL Sample Clock
Figure 65. Differential CML Sample Clock
Figure 66. Clock Output Clocking the AD9208

Clock Duty Cycle Considerations

Typical high speed ADCs use both clock edges to generate a variety of internal timing signals. The AD9208 contains an internal clock divider and a duty cycle stabilizer comprised of DCS1 and DCS2, which is enabled by default. In applications where the clock duty cycle cannot be guaranteed to be 50%, a higher multiple frequency clock along with the usage of the clock divider is recommended.

When it is not possible to provide a higher frequency clock, it is recommended to turn on the DCS using Register 0x011C and Register 0x011E. Figure 67 shows the different controls to the AD9208 clock inputs. The output of the divider offers a 50% duty cycle, high slew rate (fast edge) clock signal to the internal ADC. See the Memory Map section for more details on using this feature.

Input Clock Divider

The AD9208 contains an input clock divider with the ability to divide the input clock by 1, 2, or 4. Select the divider ratios using Register 0x0108 (see Figure 67).

The maximum frequency at the CLK± inputs is 6 GHz, which is the limit of the divider. In applications where the clock input is a multiple of the sample clock, take care to program the appropriate divider ratio into the clock divider before applying the clock signal; this ensures that the current transients during device startup are controlled.
Figure 67. Clock Divider Circuit

The AD9208 clock divider can be synchronized using the external SYSREF± input. A valid SYSREF± signal causes the clock divider to reset to a programmable state. This synchronization feature allows multiple devices to have their clock dividers aligned to guarantee simultaneous input sampling. See the Memory Map Register Details section for more information.

Input Clock Divider ½ Period Delay Adjust

The input clock divider in the AD9208 provides phase delay in increments of ½ the input clock cycle. Program Register 0x0109 to enable this delay independently for each channel. Changing this register does not affect the stability of the JESD204B link.

Clock Fine Delay and Superfine Delay Adjust

Adjust the AD9208 sampling edge instant by writing to Register 0x0110, Register 0x0111, and Register 0x0112. Bits[2:0] of Register 0x0110 enable the selection of the fine delay, or the fine delay with superfine delay. The fine delay allows the user to delay the clock edges with 16 step or 192 step delay options. The superfine delay is an unsigned control to adjust the clock delay in superfine steps of 0.25 ps each.

Register 0x0112, Bits[7:0] offer the user the option to delay the clock in 192 delay steps. Register 0x0111, Bits[7:0] offer the user the option to delay the clock in 128 superfine steps. These values can be programmed individually for each channel. To use the superfine delay option, set the clock delay control in Register 0x0110, Bits[2:0] to 0x2 or 0x6. Figure 68 shows the controls available to the clock dividers within AD9208. It is recommended to apply the same delay settings to the digital delay circuits as are applied to the analog delay circuits to maintain sample accuracy through the pipe.
Figure 68. Clock Divider Phase and Delay Controls

The clock delay adjustment takes effect immediately when it is enabled via SPI writes. Enabling the clock fine delay adjust in Register 0x0110 causes a datapath reset. However, the contents of Register 0x0111 and Register 0x0112 can be changed without affecting the stability of the JESD204B link.

Clock Coupling Considerations

The AD9208 has many different domains within the analog supply that control various aspects of the data conversion. The clock domain is supplied by Pin A4, Pin A5, Pin A10, Pin A11, Pin B4, and Pin B11 on the analog supply, AVDD1 (0.975 V) and Pin A6, Pin A9, Pin B6, Pin B7, Pin B8, Pin B9, Pin C6, Pin C7, Pin C8, Pin C9, Pin D7, and Pin D8 on the ground (AGND) side. To minimize coupling between the clock supply domain and the other analog domains, it is recommended to add a supply Q factor reduction circuitry (de-Q) for Pin A4 and Pin A11, as well as Pin B4 and Pin B11, as shown in Figure 69.
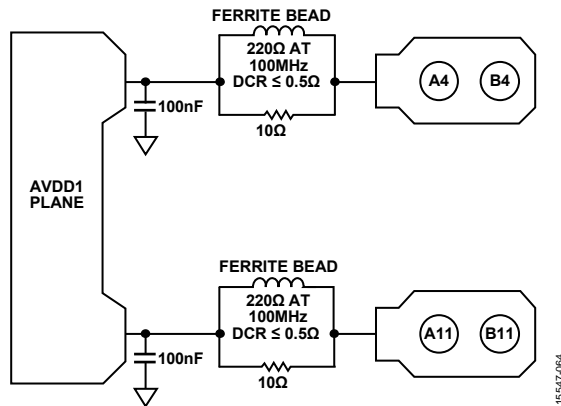

Figure 69. De-Q Network Recommendation for the Clock Domain Supply

Clock Jitter Considerations

High speed, high resolution ADCs are sensitive to the quality of the clock input. Calculate the degradation in SNR at a given input frequency (f_A) due only to aperture jitter (t_J) by

$$SNR_{JITTER} = -20 \times \log_{10}(2 \times \pi \times f_A \times t_J)$$

In this equation, the rms aperture jitter represents the root mean square of all jitter sources, including the clock input, analog input signal, and ADC aperture jitter specifications.

IF undersampling applications are particularly sensitive to jitter (see Figure 70).
Figure 70. Ideal SNR vs. Input Frequency and Jitter

Treat the clock input as an analog signal when aperture jitter may affect the dynamic range of the AD9208. Separate power supplies for clock drivers from the ADC output driver supplies to avoid modulating the clock signal with digital noise. If the clock is generated from another type of source (by gating, dividing, or other methods), retime the clock by the original clock at the last step. Refer to the AN-501 Application Note and the AN-756 Application Note for more in depth information about jitter performance as it relates to ADCs.

Figure 71 shows the estimated SNR of the AD9208 across input frequency for different clock induced jitter values. Estimate the SNR by using the following equation:

$$SNR \text{ (dBFS)} = -10\log_{10}\left(10^{\left(\frac{-SNR_{ADC}}{10}\right)} + 10^{\left(\frac{-SNR_{JITTER}}{10}\right)}\right)$$
Figure 71. Estimated SNR Degradation for the AD9208 vs. Input Frequency and RMS Jitter

POWER-DOWN/STANDBY MODE

The AD9208 has a PDWN/STBY pin that can be used to configure the device in power-down or standby mode. The default operation is PDWN. The PDWN/STBY pin is a logic high pin. When in power-down mode, the JESD204B link is disrupted. The power-down option can also be set via Register 0x003F and Register 0x0040.

In standby mode, the JESD204B link is not disrupted and transmits zeros for all converter samples. Change this transmission using Register 0x0571, Bit 7 to select /K/ characters.

TEMPERATURE DIODE

The AD9208 contains diode-based temperature sensors. The diodes output voltages commensurate to the temperature of the silicon. There are multiple diodes on the die, but the results established using the temperature diode at the central location of the die can be regarded as representative of the entire die. However, in applications where only one channel is used (the other channel being in a power-down state), it is recommended to read the temperature diode corresponding to the channel that is on. The Figure 72 shows the locations of the diodes in the AD9208 with voltages that can be output to the VREF pin. In each location, there is a pair of diodes, one of which is 20× the size of the other. It is recommended to use both diodes in a location to obtain an accurate estimate of the die temperature. For more information, see the AN-1432 Application Note, *Practical Thermal Modeling and Measurements in High Power ICs*.
Figure 72. Temperature Diode Locations in the Die

The temperature diode voltages can be exported to the VREF pin using the SPI. Use Register 0x18E6 to enable or disable diodes. It is important to note that other voltages may be exported to the VREF pin at the same time, which can result in undefined behavior. To ensure a proper readout, switch off all other voltage exporting circuits as described in this section. Figure 73 shows the block diagram of the controls that are required to enable the diode voltage readout.
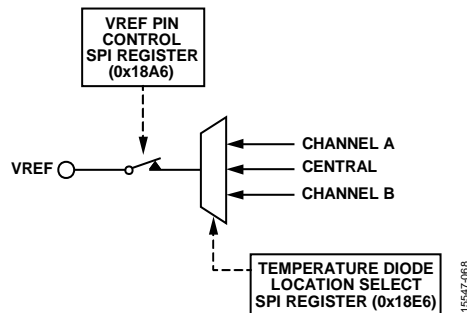

Figure 73. Register Controls to Output Temperature Diode Voltage on the VREF Pin

The SPI writes required to export the central temperature diode are as follows (see Table 46 for more information):

1. Set Register 0x0008 to 0x03 to select both channels.
2. Set Register 0x18E3 to 0x00 to turn off V_{CM} export.
3. Set Register 0x18A6 to 0x00 to turn off voltage reference export.
4. Set Register 0x18E6 to 0x01 to turn on voltage export of the central 1× temperature diode. The typical voltage response of the temperature diode is shown in Figure 74. Although this voltage represents the die temperature, it is recommended to take measurements from a pair of diodes for improved accuracy. The following step explains how to enable the 20× diode.
5. Set Register 0x18E6 to 0x02 to turn on the second central temperature diode of the pair, which is 20× the size of the first. For the method using two diodes simultaneously to achieve a more accurate result, see the AN-1432 Application Note, *Practical Thermal Modeling and Measurements in High Power ICs*.
Figure 74. Typical Voltage Response of the 1× Temperature Diode

The relationship between the measured delta voltage (ΔV) and the junction temperature in °C is shown in Figure 75.
Figure 75. Junction Temperature vs. ΔV (mV)

ADC OVERRANGE AND FAST DETECT

In receiver applications, it is desirable to have a mechanism to reliably determine when the converter is about to be clipped. The standard overrange bit in the JESD204B outputs provides information on the state of the analog input that is of limited usefulness. Therefore, it is helpful to have a programmable threshold below full scale that allows time to reduce the gain before the clip actually occurs. In addition, because input signals can have significant slew rates, the latency of this function is of major concern. Highly pipelined converters can have significant latency. The AD9208 contains fast detect circuitry for individual channels to monitor the threshold and assert the FD_A and FD_B pins.

ADC OVERRANGE

The ADC overrange indicator is asserted when an overrange is detected on the input of the ADC. The overrange indicator can be embedded within the JESD204B link as a control bit (when CSB > 0). The latency of this overrange indicator matches the sample latency.

The AD9208 also records any overrange condition in any of the eight virtual converters. For more information on the virtual converters, refer to Figure 84. The overrange status of each virtual converter is registered as a sticky bit in Register 0x0563. The contents of Register 0x0563 can be cleared using Register 0x0562, by toggling the bits corresponding to the virtual converter to set and reset position.

FAST THRESHOLD DETECTION (FD_A AND FD_B)

The FD_A or FD_B pin is immediately set whenever the absolute value of the input signal exceeds the programmable upper threshold level. The FD bit is only cleared when the absolute value of the input signal drops below the lower threshold level for greater than the programmable dwell time. This feature provides hysteresis and prevents the FD bit from excessively toggling.

The operation of the upper threshold and lower threshold registers, along with the dwell time registers, is shown in Figure 76.

The FD indicator is asserted if the input magnitude exceeds the value programmed in the fast detect upper threshold registers, located at Register 0x0247 and Register 0x0248. The selected threshold register is compared with the signal magnitude at the output of the ADC. The fast upper threshold detection has a latency of 28 clock cycles (maximum). The approximate upper threshold magnitude is defined by

Upper Threshold Magnitude (dBFS) = 20log(*Threshold Magnitude*/2^{13})

The FD indicators are not cleared until the signal drops below the lower threshold for the programmed dwell time. The lower threshold is programmed in the fast detect lower threshold registers, located at Register 0x0249 and Register 0x024A. The fast detect lower threshold register is a 13-bit register that is compared with the signal magnitude at the output of the ADC. This comparison is subject to the ADC pipeline latency, but is accurate in terms of converter resolution. The lower threshold magnitude is defined by

Lower Threshold Magnitude (dBFS) = 20log(*Threshold Magnitude*/2^{13})

For example, to set an upper threshold of −6 dBFS, write 0xFFF to Register 0x0247 and Register 0x0248. To set a lower threshold of −10 dBFS, write 0xA1D to Register 0x0249 and Register 0x024A.

The dwell time can be programmed from 1 to 65,535 sample clock cycles by placing the desired value in the fast detect dwell time registers, located at Register 0x024B and Register 0x024C. See Register 0x0040 and Register 0x0245 to Register 0x024C in the Memory Map section (see Table 46) for more details.
Figure 76. Threshold Settings for the FD_A and FD_B Signals

ADC APPLICATION MODES AND JESD204B Tx CONVERTER MAPPING

The AD9208 contains a configurable signal path that allows different features to be enabled for different applications. These features are controlled using the chip application mode register, Register 0x0200. The chip operating mode is controlled by Bits[3:0] in this register, and the chip Q ignore is controlled by Bit 5.

The AD9208 contains the following modes:

- Full bandwidth mode: two 14-bit ADC cores running at full sample rate.
- DDC mode: up to four digital downconverter (DDC) channels.

After the chip application mode is selected, the output decimation ratio is set using the chip decimation ratio in Register 0x0201, Bits[3:0]. The output sample rate = ADC sample rate/the chip decimation ratio.

To support the different application layer modes, the AD9208 treats each sample stream (real, I, or Q) as originating from separate virtual converters.

Table 11 shows the number of virtual converters required and the transport layer mapping when channel swapping is disabled. Figure 77 shows the virtual converters and their relationship to the DDC outputs when complex outputs are used.

Each DDC channel outputs either two sample streams (I/Q) for the complex data components (real + imaginary), or one sample stream for real (I) data. The AD9208 can be configured to use up to eight virtual converters, depending on the DDC configuration.

The I/Q samples are always mapped in pairs with the I samples mapped to the first virtual converter and the Q samples mapped to the second virtual converter. With this transport layer mapping, the number of virtual converters are the same whether a single real converter is used along with a digital downconverter block producing I/Q outputs, or whether an analog downconversion is used with two real converters producing I/Q outputs.

Figure 78 shows a block diagram of the two scenarios described for I/Q transport layer mapping.

Table 11. Virtual Converter Mapping

Number of Virtual Converters Supported	Chip Operating Mode (Reg. 0x0200, Bits[3:0])	Chip Q Ignore (0x0200, Bit 5)	Virtual Converter Mapping							
			0	1	2	3	4	5	6	7

PROGRAMMABLE FIR FILTERS

SUPPORTED MODES

The AD9208 supports the following modes of operation (the asterisk symbol (*) denotes convolution):

- Real 48-tap filter for each I/Q channel (see Figure 79)
  - DOUT_I[n] = DIN_I[n] * XY_I[n]
  - DOUT_Q[n] = DIN_Q[n] * XY_Q[n]
- Real 96-tap filter for on either I or Q channel (see Figure 80)
  - DOUT_I[n] = DIN_I[n] * XY_I[n]
  - DOUT_Q[n] = DIN_Q[n] * XY_Q[n]
- Real set of two cascaded 24-tap filters for each I/Q channel (see Figure 81)
  - DOUT_I[n] = DIN_I[n] * X_I[n] * Y_I[n]
  - DOUT_Q[n] = DIN_Q[n] * X_Q[n] * Y_Q[n]

- Half complex filter using two real 48-tap filters for the I/Q channels (see Figure 82)
  - DOUT_I[n] = DIN_I[n]
  - DOUT_Q[n] = DIN_Q[n] * XY_Q[n] + DIN_I[n] * XY_I[n]
- Full complex filter using four real 24-tap filters for the I/Q channels (see Figure 83)
  - DOUT_I[n] = DIN_I[n] * X_I[n] + DIN_Q[n] * Y_Q[n]
  - DOUT_Q[n] = DIN_Q[n] * X_Q[n] + DIN_I[n] * Y_I[n]

PROGRAMMING INSTRUCTIONS

Use the following procedure to set up the programmable FIR filter:

1. Enable the sample clock to the device.
2. Configure the mode registers as follows:
   a. Set the device index to Channel A (I path) (Register 0x0008 = 0x01).
   b. Set the I path mode (I mode) and gain in Register 0x0DF8 and Register 0x0DF9 (see Table 12 and Table 13).
   c. Set the device index to Channel B (Q path) (Register 0x0008 = 0x02).
   d. Set the Q path mode (Q mode) and gain in Register 0x0DF8 and Register 0x0DF9.
3. Wait at least 5 μs to allow the programmable filter to power up.
4. Program the I path coefficients to the internal shadow registers as follows:
   a. Set the device index to Channel A (I path) (Register 0x0008 = 0x01).
   b. Program the XI coefficients in Register 0x0E00 to Register 0x0E2F (see Table 14 and Table 15).
   c. Program the YI coefficients in Register 0x0F00 to Register 0x0F2F (see Table 14 and Table 15).
   d. Program the tapped delay in Register 0x0F30 (note that this step is optional).
5. Program the Q path coefficients to the internal shadow registers as follows:
   a. Set the device index to Channel B (Q path) (Register 0x0008 = 0x02).
   b. Set the Q path mode and gain in Register 0x0DF8 and Register 0x0DF9 (see Table 12 and Table 13).
   c. Program the XQ coefficients in Register 0x0E00 to Register 0x0E2F (see Table 14 and Table 15)
   d. Program the YQ coefficients in Register 0x0F00 to Register 0x0F2F (see Table 14 and Table 15)
   e. Program the tapped delay in Register 0x0F30 (note that this step is optional).
6. Set the chip transfer bit using either of the following methods (note that setting the chip transfer bit applies the programmed shadow coefficients to the filter):
   a. Via the register map using the write the chip transfer bit (Register 0x000F = 0x01).
   b. Via a GPIO pin, as follows:
      i. Configure one of the GPIO pins as the chip transfer bit in Register 0x0040 to Register 0x0042.
      ii. Toggle the GPIO pin to initiate the chip transfer (the rising edge is triggered).
7. When the I or Q path mode register changes in Register 0x0DF8, all coefficients must be reprogrammed.

Table 12. Register 0x0DF8 Definition

Bit(s)	Description
[7:3]	Reserved
[2:0]	Filter mode (I mode or Q mode)
	000: filters bypassed
	001: real 24-tap filter (X only)
	010: real 48-tap filter (X and Y together)
	100: real set of two cascaded 24-tap filters (X then Y cascaded)
	101: full complex filter using four real 24-tap filters for the A/B channels (opposite channel must also be set to 101)
	110: half complex filter using two real 48-tap filters + 48-tap delay line (X and Y together) (opposite channel must also be set to 010)
	111: real 96-tap filter (XI, YI, XQ, and YQ together) (opposite channel must be set to 000)

Table 13. Register 0x0DF9 Definition

Bit(s)	Description

DIGITAL DOWNCONVERTER (DDC)

The AD9208 includes four digital downconverters (DDC0 to DDC3) that provide filtering and reduce the output data rate. This digital processing section includes an NCO, multiple decimating FIR filters, a gain stage, and a complex to real conversion stage. Each of these processing blocks has control lines that allow it to be independently enabled and disabled to provide the desired processing function. The digital downconverter can be configured to output either real data or complex output data.

The DDCs output a 16-bit stream. To enable this operation, the converter number of bits, N, is set to a default value of 16, even though the analog core only outputs 14 bits. In full bandwidth operation, the ADC outputs are the 14-bit word followed by two zeros, unless the tail bits are enabled.

DDC I/Q INPUT SELECTION

The AD9208 has two ADC channels and four DDC channels. Each DDC channel has two input ports that can be paired to support both real and complex inputs through the I/Q crossbar mux. For real signals, both DDC input ports must select the same ADC channel (that is, DDC Input Port I = ADC Channel A and DDC Input Port Q = ADC Channel A). For complex signals, each DDC input port must select different ADC channels (that is, DDC Input Port I = ADC Channel A and DDC Input Port Q = ADC Channel B).

The inputs to each DDC are controlled by the DDC input selection registers (Register 0x0311, Register 0x0331, Register 0x0351, and Register 0x0371). See Table 46 for information on how to configure the DDCs.

DDC I/Q OUTPUT SELECTION

Each DDC channel has two output ports that can be paired to support both real and complex outputs. For real output signals, only the DDC Output Port I is used (the DDC Output Port Q is invalid). For complex I/Q output signals, both DDC Output Port I and DDC Output Port Q are used.

The I/Q outputs to each DDC channel are controlled by the DDC complex to real enable bit, Bit 3, in the DDC control registers (Register 0x0310, Register 0x0330, Register 0x0350, and Register 0x0370).

The chip Q ignore bit in the chip mode register (Register 0x0200, Bit 5) controls the chip output muxing of all the DDC channels. When all DDC channels use real outputs, set this bit high to ignore all DDC Q output ports. When any of the DDC channels are set to use complex I/Q outputs, the user must clear this bit to use both DDC Output Port I and DDC Output Port Q. For more information, see Figure 101.

DDC GENERAL DESCRIPTION

The four DDC blocks are used to extract a portion of the full digital spectrum captured by the ADC(s). They are intended for IF sampling or oversampled baseband radios requiring wide bandwidth input signals.

Each DDC block contains the following signal processing stages:

- Frequency translation stage (optional)
- Filtering stage
- Gain stage (optional)
- Complex to real conversion stage (optional)

DDC Frequency Translation Stage (Optional)

This stage consists of a phase coherent NCO and quadrature mixers that can be used for frequency translation of both real or complex input signals. The phase coherent NCO allows an infinite number of frequency hops that are all referenced back to a single synchronization event. It also includes 16 shadow registers for fast switching applications. This stage shifts a portion of the available digital spectrum down to baseband.

DDC Filtering Stage

After shifting down to baseband, this stage decimates the frequency spectrum using multiple low-pass finite impulse response (FIR) filters for rate conversion. The decimation process lowers the output data rate, which in turn reduces the output interface rate.

DDC Gain Stage (Optional)

Because of losses associated with mixing a real input signal down to baseband, this stage compensates by adding an additional 0 dB or 6 dB of gain.

DDC Complex to Real Conversion Stage (Optional)

When real outputs are necessary, this stage converts the complex outputs back to real by performing an $f_S/4$ mixing operation plus a filter to remove the complex component of the signal.

Figure 84 shows the detailed block diagram of the DDCs implemented in the AD9208.

Figure 85 shows an example usage of one of the four DDC channels with a real input signal and four half-band filters (HB4 + HB3 + HB2 + HB1) used. It shows both complex (decimate by 16) and real (decimate by 8) output options.
Figure 84. DDC Detailed Block Diagram
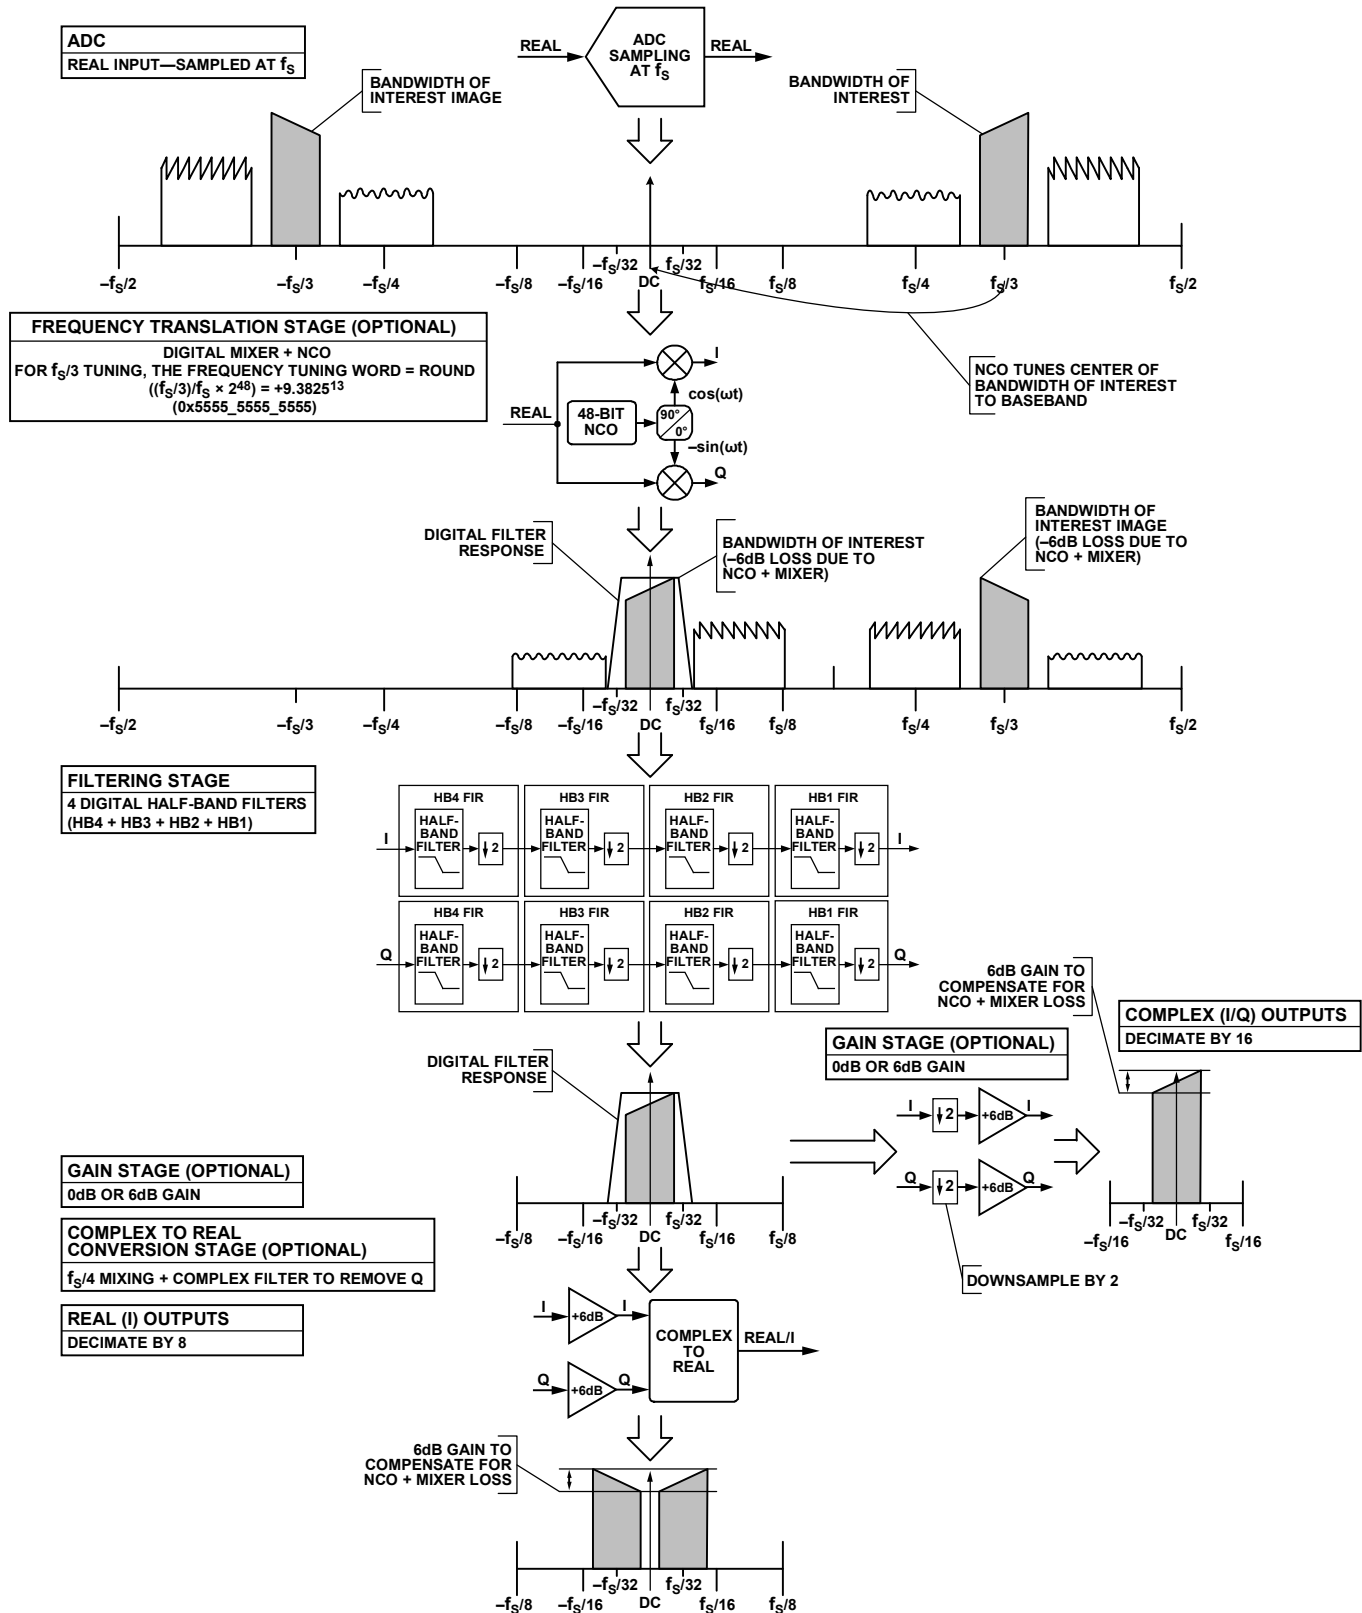

Figure 85. DDC Theory of Operation Example (Real Input)

DDC FREQUENCY TRANSLATION

DDC Frequency Translation General Description

Frequency translation is accomplished by using a 48-bit complex NCO with a digital quadrature mixer. This stage translates either a real or complex input signal from an IF to a baseband complex digital output (carrier frequency = 0 Hz).

The frequency translation stage of each DDC can be controlled individually and supports four different IF modes using Bits[5:4] of the DDC control registers (Register 0x0310, Register 0x0330, Register 0x0350, and Register 0x0370). These IF modes are

- Variable IF mode
- 0 Hz IF or zero IF (ZIF) mode
- $f_S/4$ Hz IF mode
- Test mode

Variable IF Mode

In this mode, the NCO and mixers are enabled. NCO output frequency can be used to digitally tune the IF frequency.

0 Hz IF (ZIF) Mode

In this mode, the mixers are bypassed, and the NCO is disabled.

$f_S/4$ Hz IF Mode

In this mode, the mixers and the NCO are enabled in downmixing by $f_S/4$ mode to save power.

Test Mode

In this mode, input samples are forced to 0.999 to positive full scale. The NCO is enabled. This test mode allows the NCOs to directly drive the decimation filters.

Figure 86 and Figure 87 show examples of the frequency translation stage for both real and complex inputs.
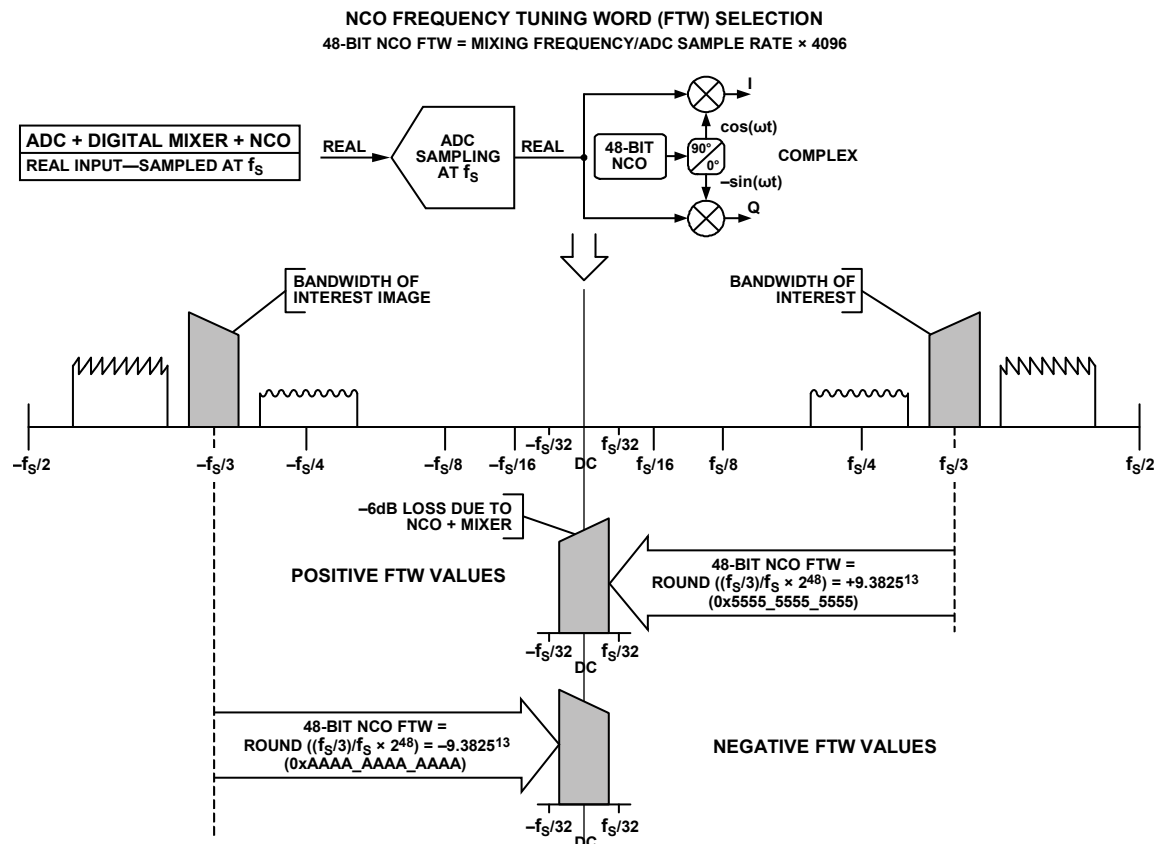

Figure 86. DDC NCO Frequency Tuning Word Selection—Real Inputs

NCO FREQUENCY TUNING WORD (FTW) SELECTION
48-BIT NCO FTW = MIXING FREQUENCY/ADC SAMPLE RATE × 2^{48}
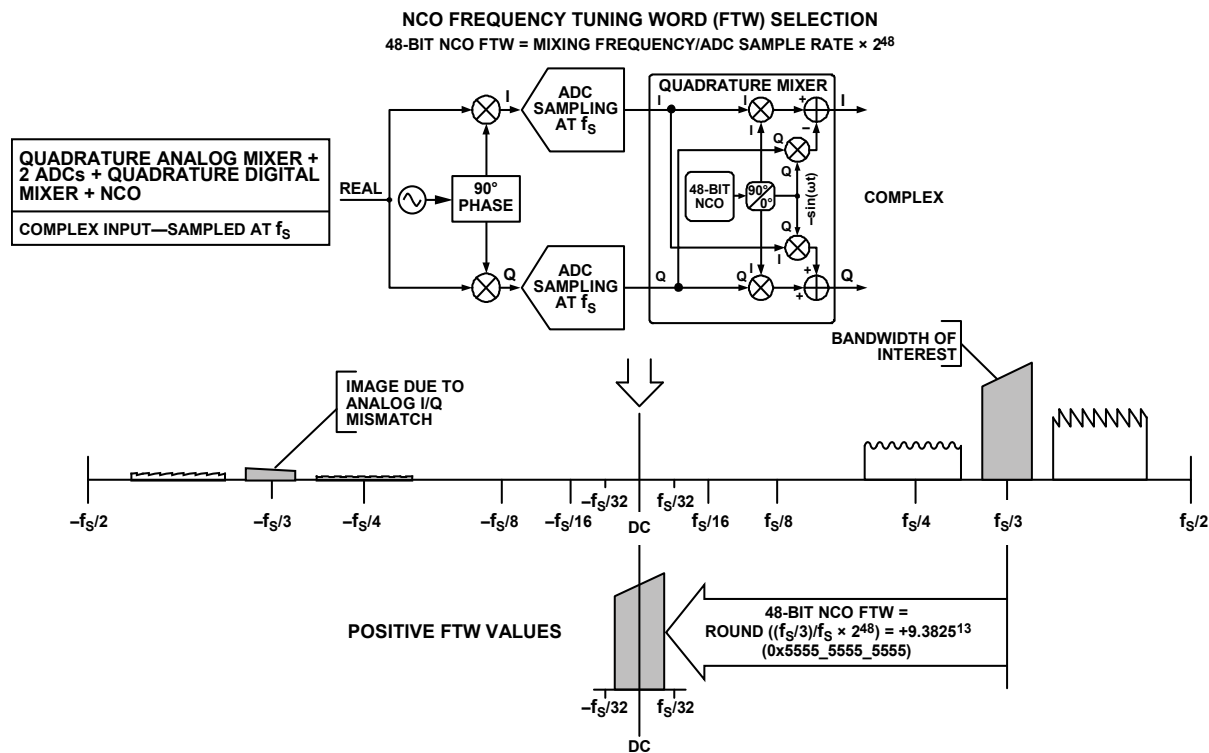

Figure 87. DDC NCO Frequency Tuning Word Selection—Complex Inputs

DDC NCO Description

Each DDC contains one NCO. Each NCO enables the frequency translation process by creating a complex exponential frequency ($e^{-j\omega ct}$), which can be mixed with the input spectrum to translate the desired frequency band of interest to dc, where it can be filtered by the subsequent low-pass filter blocks to prevent aliasing.

When placed in variable IF mode, the NCO supports two different additional modes.

DDC NCO Programmable Modulus Mode

This mode supports >48-bit frequency tuning accuracy for applications that require exact rational (M/N) frequency synthesis at a single carrier frequency. In this mode, the NCO is set up by providing the following:

- 48-bit frequency tuning word (FTW)
- 48-bit Modulus A word (MAW)
- 48-bit Modulus B word (MBW)
- 48-bit phase offset word (POW)

DDC NCO Coherent Mode

This mode allows an infinite number of frequency hops where the phase is referenced to a single synchronization event at time 0. This mode is useful when phase coherency must be maintained when switching between different frequency bands. In this mode, the user can switch to any tuning frequency without the need to reset the NCO. Although only one FTW is required, the NCO contains 16 shadow registers for fast-switching applications. Selection of the shadow registers is controlled by the CMOS GPIO pins or through the register map of the SPI. In this mode, the NCO can be set up by providing the following:

- Up to sixteen 48-bit FTWs.
- Up to sixteen 48-bit POWs.
- The 48-bit MAW must be set to zero in coherent mode.

Figure 88 shows a block diagram of one NCO and its connection to the rest of the design. The coherent phase accumulator block contains the logic that allows an infinite number of frequency hops. The gray lines in Figure 88 represent SPI control lines.

FTW = FREQUENCY TUNING WORD
POW = PHASE OFFSET WORD
MAW = MODULUS A WORD (NUMERATOR)
MBW = MODULUS B WORD (DENOMINATOR)
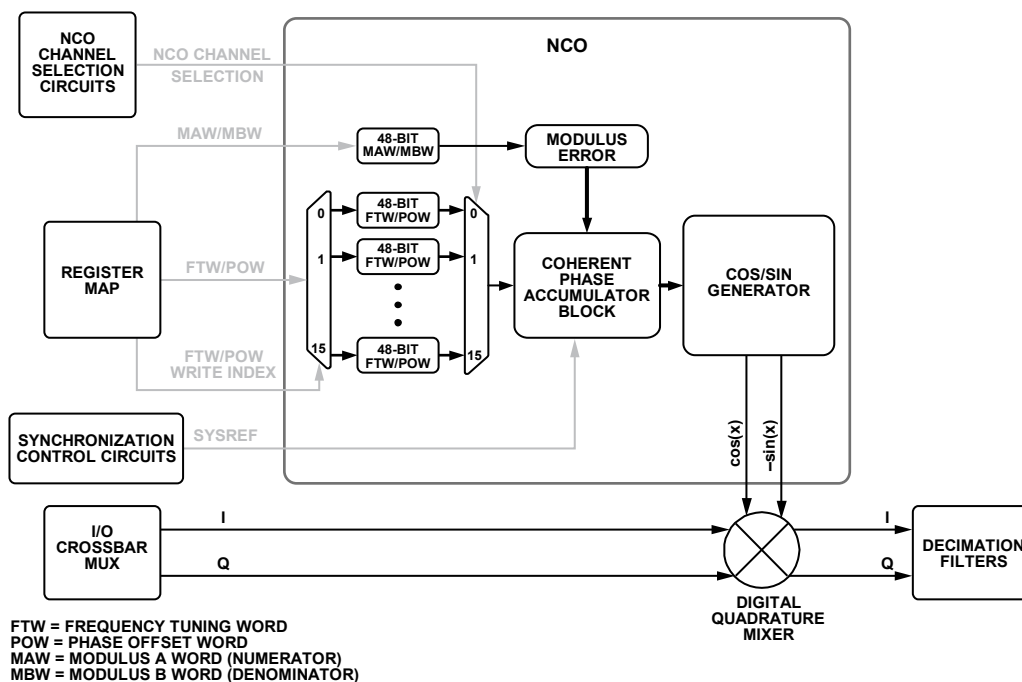

Figure 88. NCO + Mixer Block Diagram

NCO FTW/POW/MAW/MAB Description

The NCO frequency value is determined by the following settings:

- 48-bit twos complement number entered in the FTW
- 48-bit unsigned number entered in the MAW
- 48-bit unsigned number entered in the MBW

Frequencies between $-f_S/2$ and $+f_S/2$ ($f_S/2$ excluded) are represented using the following values:

- FTW = 0x8000_0000_0000 and MAW = 0x0000_0000_0000 represents a frequency of $-f_S/2$.
- FTW = 0x0000_0000_0000 and MAW = 0x0000_0000_0000 represents dc (frequency is 0 Hz).
- FTW = 0x7FFF_FFFF_FFFF and MAW = 0x0000_0000_0000 represents a frequency of $+f_S/2$.

NCO FTW/POW/MAW/MAB Programmable Modulus Mode

For programmable modulus mode, the MAW must be set to a nonzero value (not equal to 0x0000_0000_0000). This mode is only needed when frequency accuracy of >48 bits is required. One example of a rational frequency synthesis requirement that requires >48 bits of accuracy is a carrier frequency of 1/3 the sample rate. When frequency accuracy of ≤48 bits is required, coherent mode must be used (see the NCO FTW/POW/ MAW/MAB Coherent Mode section).

In programmable modulus mode, the FTW, MAW, and MBW must satisfy the following four equations (for a detailed description of the programmable modulus feature, see the DDS architecture described in the AN-953 Application Note):

$$\frac{\mathrm{mod}(f_c, f_s)}{f_s} = \frac{M}{N} = \frac{FTW + \dfrac{MAW}{MBW}}{2^{48}} \qquad (1)$$

$$FTW = \mathrm{floor}(2^{48}\frac{\mathrm{mod}(f_c, f_s)}{f_s}) \qquad (2)$$

$$MAW = \mathrm{mod}(2^{48} \times M, N) \qquad (3)$$

$$MBW = N \qquad (4)$$

where:
f_C is the desired carrier frequency.
f_S is the ADC sampling frequency.
M is the integer representing the rational numerator of the frequency ratio.
N is the integer representing the rational denominator of the frequency ratio.
FTW is the 48-bit twos complement number representing the NCO FTW.
MAW is the 48-bit unsigned number representing the NCO MAW (must be $<2^{47}$).
MBW is the 48-bit unsigned number representing the NCO MBW.
$\mathrm{mod}(x)$ is a remainder function. For example, $\mathrm{mod}(110,100) = 10$ and for negative numbers, $\mathrm{mod}(-32,10) = -2$.
$\mathrm{floor}(x)$ is defined as the largest integer less than or equal to x. For example, $\mathrm{floor}(3.6) = 3$.

Note that Equation 1 to Equation 4 apply to the aliasing of signals in the digital domain (that is, aliasing introduced when digitizing analog signals).

M and N are integers reduced to their lowest terms. MAW and MBW are integers reduced to their lowest terms. When MAW is set to zero, the programmable modulus logic is automatically disabled.

For example, if the ADC sampling frequency (f_S) is 3000 MSPS and the carrier frequency (f_C) is 1001.5 MHz, then,

$$\frac{\mathrm{mod}(1001.5, 3000)}{3000} = \frac{M}{N} = \frac{2003}{6000}$$

$$FTW = \mathrm{floor}(2^{48}\frac{\mathrm{mod}(1001.5, 3000)}{3000})$$
$$= \text{0x5576\_19F0\_FB38}$$

$$MAW = \mathrm{mod}(2^{48} \times 2003, 6000) = \text{0x0000\_0000\_0F80}$$

$$MBW = \text{0x0000\_0000\_1770}$$

The actual carrier frequency can be calculated based on the following equation:

$$f_{C\_ACTUAL} = \frac{FTW + \dfrac{MAW}{MBW} \times f_S}{2^{48}}$$

For the previous example, the actual carrier frequency (f_{C_ACTUAL}) is

$$f_{C\_ACTUAL}$$
$$= \frac{\text{0x5576\_19F0\_FB38} \times \dfrac{\text{0x0000\_0000\_0F80}}{\text{0x0000\_0000\_1770}}}{2^{48}}$$
$$= 1001.5\,\mathrm{MHz}$$

A 48-bit POW is available for each NCO to create a known phase relationship between multiple chips or individual DDC channels inside the chip.

While in programmable modulus mode, the FTW and POW registers can be updated at any time while still maintaining deterministic phase results in the NCO. However, the following procedure must be followed to update the MAW and/or MBW registers to ensure proper operation of the NCO:

1. Write to the MAW and MBW registers for all the DDCs.
2. Synchronize the NCOs either through the DDC soft reset bit accessible through the SPI or through the assertion of the SYSREF± pin (see the Memory Map section).

NCO FTW/POW/MAW/MAB Coherent Mode

For coherent mode, the NCO MAW must be set to zero (0x0000_0000_0000). In this mode, the NCO FTW can be calculated by the following equation:

$$FTW = \text{round}(2^{48}\frac{\text{mod}(f_c, f_s)}{f_s}) \qquad (5)$$

where:
FTW is the 48-bit twos complement number representing the NCO FTW.
f_s is the ADC sampling frequency.
f_C is the desired carrier frequency.
$\text{mod}(x)$ is a remainder function. For example $\text{mod}(110,100) = 10$ and for negative numbers, $\text{mod}(-32,10) = -2$.
$\text{round}(x)$ is a rounding function. For example $\text{round}(3.6) = 4$ and for negative numbers, $\text{round}(-3.4) = -3$.

Note that Equation 5 applies to the aliasing of signals in the digital domain (that is, aliasing introduced when digitizing analog signals). The MAW must be set to zero to use coherent mode. When MAW is zero, the programmable modulus logic is automatically disabled.

For example, if the ADC sampling frequency (f_S) is 3000 MSPS and the carrier frequency (f_C) is 416.667 MHz, then,

$$NCO\_FTW$$
$$= \text{round}(2^{48}\frac{\text{mod}(416.667, 3000)}{3000})$$
$$= 0x2EC6\_C03A\_8E23$$

The actual carrier frequency can be calculated based on the following equation:

$$f_{C\_ACTUAL} = \frac{FTW \times f_S}{2^{48}}$$

For the previous example, the actual carrier frequency (f_{C_ACTUAL}) is

$$f_{C\_ACTUAL} = \frac{416.667 \times 3000}{2^{48}} = 416.66699 \text{ MHz}$$

A 48-bit POW is available for each NCO to create a known phase relationship between multiple chips or individual DDC channels inside the chip.

While in coherent mode, the FTW and POW registers can be updated at any time while still maintaining deterministic phase results in the NCO.

NCO Channel Selection

When configured in coherent mode, only one FTW is required in the NCO. In this mode, the user can switch to any tuning frequency without the need to reset the NCO by writing to the FTW directly. However, for fast-switching applications, where either all FTWs are known beforehand or it is possible to queue up the next set of FTWs, the NCO contains 16 additional shadow registers (see Figure 88). These shadow registers are hereafter referred to as the NCO channels.

Figure 89 shows a simplified block diagram of the NCO channel selection block. The gray lines in Figure 89 represent SPI control lines.
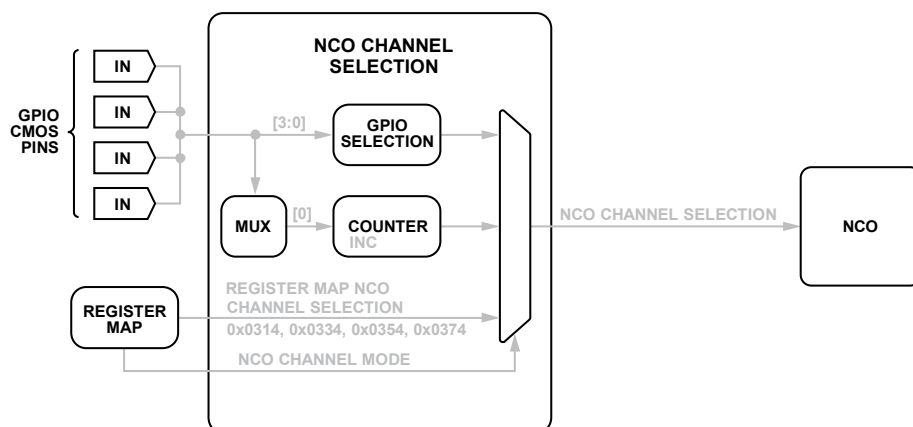

Figure 89. NCO Channel Selection Block

Only one NCO channel is active at a time and NCO channel selection is controlled either by the CMOS GPIO pins or through the register map.

Each NCO channel selector supports three different modes, described as follows:

- GPIO level control mode. In this mode, the GPIO pins determine the exact NCO channel selected.
- GPIO edge control mode. A low to high transition on a single GPIO pin determines the exact NCO channel selected. The internal channel selection counter is reset by either SYSREF± or by the DDC soft reset.
- Register map mode. In this mode, the NCO channel selected is determined directly through the register map.

The following procedure must be followed to use GPIO level control mode for NCO channel selection:

1. Configure one or more GPIO pins as NCO channel selection inputs. The GPIO pins not configured as NCO channel selection inputs are internally tied low.
   a. To use GPIO_A0, write Bits[2:0] in Register 0x0040 to 0x6 and Bits[3:0] in Register 0x0041 to 0x0.
   b. To use GPIO_B0, write Bits[5:3] in Register 0x0040 to 0x6 and Bits[7:4] in Register 0x0041 to 0x0.
   c. To use GPIO_A1, write Bits[3:0] in Register 0x0042 to 0x0.
   d. To use GPIO_B1, write Bits[7:4] in Register 0x0042 to 0x0.
2. Configure the NCO channel selector in GPIO level control mode by setting Bits[7:4] in the NCO control registers (Register 0x0314, Register 0x0334, Register 0x0354, and Register 0x0374) to 0x1 through 0x6, depending on the desired GPIO pin order.
3. Select the desired NCO channel through the GPIO pins.

The following procedure must be followed to use GPIO edge control mode for NCO channel selection:

1. Configure one or more GPIO pins as NCO channel selection inputs.
   a. To use GPIO_A0, write Bits[2:0] in Register 0x0040 to 0x6 and Bits[3:0] in Register 0x0041 to 0x0.
   b. To use GPIO_B0, write Bits[5:3] in Register 0x0040 to 0x6 and Bits[7:4] in Register 0x0041 to 0x0.
   c. To use GPIO_A1, write Bits[3:0] in Register 0x0042 to 0x0.
   d. To use GPIO_B1, write Bits[7:4] in Register 0x0042 to 0x0.
2. Configure the NCO channel selector in GPIO edge control mode by setting Bits[7:4] in the NCO control registers (Register 0x0314, Register 0x0334, Register 0x0354, and Register 0x0374) to 0x8 through 0xB, depending on the desired GPIO pin.
3. Configure the wrap point for the NCO channel selection by setting Bits[3:0] in the NCO control registers (Register 0x0314, Register 0x0334, Register 0x0354, and Register 0x0374). A value of 4 causes the channel selection to wrap at Channel 4 (for example, 0, 1, 2, 3, 4, 0, 1, 2, 3, 4).
4. Transition the selected GPIO pin from low to high to increment the NCO channel selection.

Figure 90 shows an example use case for coherent mode using three NCO channels. In this example, NCO Channel 0 is actively downconverting Bandwidth 0 (B0), while NCO Channel 1 and Channel 2 are in standby mode and are tuned to Bandwidth 1 and Bandwidth 2 (B1 and B2), respectively.
Figure 90. NCO Coherent Mode with Three NCO Channels (B0 Selected)

The phase coherent NCO switching feature allows an infinite number of frequency hops that are all phase coherent. The initial phase of the NCO is established at time, t_0, from SYSREF± synchronization. Switching the NCO FTW does not affect the phase. With this feature, only one FTW is required, but the user may wish to use all 16 channels to queue up the next hop.

After SYSREF± synchronization at startup, all NCOs across multiple chips are inherently synchronized.

Setting Up the Multichannel NCO Feature

The first step to configure the multichannel NCO is to program the FTWs. The AD9208 memory map has an FTW index register for each DDC. This index determines which NCO channel receives the FTW from the register map. The following sequence describes the method for programming the FTWs:

1. Write the FTW index register with the desired DDC channel.
2. Write the FTW with the desired value. This value is applied to the NCO channel index mentioned in Step 1.
3. Repeat Step 1 and Step 2 for other NCO channels.

After setting the FTWs, the user must then select an active NCO channel. This selection can be performed either through the SPI registers or through the external GPIO pins. The following sequence describes the method for selecting the active NCO channel using the SPI:

1. Set the NCO channel select mode bits (Bits[7:4] in Register 0x0314, Register 0x0334, Register 0x0354, and Register 0x0374) to 0x0 to enable SPI selection.
2. Choose the active NCO channel using Bits[3:0] in Register 0x0314, Register 0x0334, Register 0x0354, and Register 0x0374.

The following sequence describes the method for selecting the active NCO channel using the GPIO CMOS pins:

1. Set the NCO channel select mode bits (Bits[7:4] in Register 0x0314, Register 0x0334, Register 0x0354, and Register 0x0374) to a nonzero value to enable GPIO pin selection.
2. Configure the GPIO pins as NCO channel selection inputs by writing to Register 0x0040, Register 0x0041, and Register 0x0042.
3. NCO switching is performed by externally controlling the GPIO CMOS pins.

NCO Synchronization

Each NCO contains a separate phase accumulator word (PAW). The initial reset value of each PAW is set to zero and incremented every clock cycle. The instantaneous phase of the NCO is calculated using the PAW, FTW, MAW, MBW, and POW. Due to this architecture, the FTW and POW registers can be updated at any time while still maintaining deterministic phase results in the PAW of the NCO.

Two methods can be used to synchronize multiple PAWs within the chip:

- Using the SPI. Use the DDC soft reset bit in the DDC synchronization control register (Register 0x0300, Bit 4) to reset all the PAWs in the chip. This reset is accomplished by setting the DDC soft reset bit high, and then setting this bit low. Note that this method can only be used to synchronize DDC channels within the same chip.
- Using the SYSREF± pin. When the SYSREF± pin is enabled in the SYSREF control registers (Register 0x0120 and Register 0x0121), and the DDC synchronization is enabled in the DDC synchronization control register (Register 0x0300, Bits[1:0]), any subsequent SYSREF± event resets all the PAWs in the chip. Note that this method can be used to synchronize DDC channels within the same chip or DDC channels within separate chips.

NCO Multichip Synchronization

In some applications, it is necessary to synchronize all the NCOs and local multiframe clocks (LMFCs) within multiple devices in a system. For applications requiring multiple NCO tuning frequencies in the system, a designer likely needs to generate a single SYSREF pulse at all devices simultaneously. For many systems, generating
or receiving a single-shot SYSREF pulse at all devices is challenging because of the following factors:

- Enabling or disabling the SYSREF pulse is often an asynchronous event.
- Not all clock generation chips support this feature.

For these reasons, the AD9208 contains a synchronization triggering mechanism that allows the following:

- Multichip synchronization of all NCOs and LMFCs at system startup.
- Multichip synchronization of all NCOs after applying new tuning frequencies during normal operation.

The synchronization triggering mechanism uses a master/slave arrangement, as shown in Figure 91.

MNTO = MASTER NEXT TRIGGER OUTPUT (CMOS)
SNTI = SLAVE NEXT TRIGGER INPUT (CMOS)
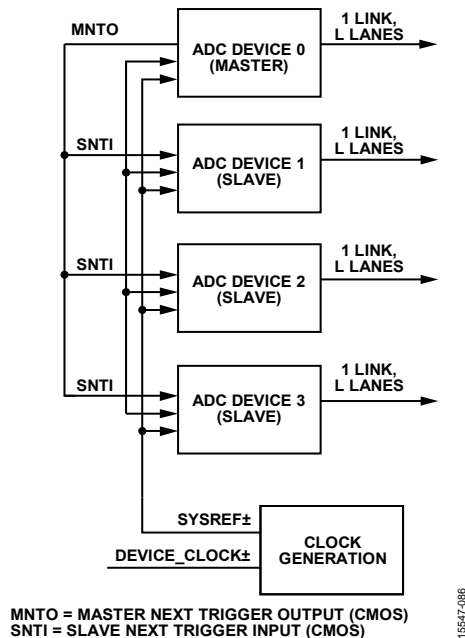

Figure 91. System Using Master/Slave Synchronization Triggering

Each device has an internal next synchronization trigger enable (NSTE) signal that controls whether the next SYSREF signal causes a synchronization event. Slave ADC devices must source their NSTE from an external slave next trigger input (SNTI) pin. Master devices can either use an external master next trigger output (MNTO) pin (default setting), or use an external SNTI pin.

See Table 46 (Register 0x0041 and Register 0x0042) to configure the FD/GPIO pins for this operation.

NCO Multichip Synchronization at Startup

Figure 92 shows a timing diagram along with the required sequence of events for NCO multichip synchronization using triggering and SYSREF at startup. Using this startup sequence synchronizes all the NCOs and LMFCs in the system at once.

NCO Multichip Synchronization During Normal Operation

See the Setting Up the Multichannel NCO Feature section.

MNTO = MASTER NEXT TRIGGER OUTPUT (CMOS)
SNTI = SLAVE NEXT TRIGGER INPUT (CMOS)
NSTE = NEXT SYNCHRONIZATION TRIGGER ENABLE
LMFC = LOCAL MULTIFRAME CLOCK
NCO = NUMERICALLY CONTROLLED OSCILLATOR
Figure 92. NCO Multichip Synchronization at Startup (Using Triggering and SYSREF)

DDC Mixer Description

When not bypassed (Register 0x0200 ≠ 0x00), the digital quadrature mixer performs a similar operation to an analog quadrature mixer. It performs the downconversion of input signals (real or complex) by using the NCO frequency as a local oscillator. For real input signals, a real mixer operation (with two multipliers) is performed. For complex input signals, a complex mixer operation (with four multipliers and two adders) is performed. The selection of real or complex inputs can be controlled individually for each DDC block using Bit 7 of the DDC control registers (Register 0x0310, Register 0x0330, Register 0x0350, and Register 0x0370).

DDC NCO + Mixer Loss and SFDR

When mixing a real input signal down to baseband, −6 dB of loss is introduced in the signal due to filtering of the negative image. An additional −0.05 dB of loss is introduced by the NCO. The total loss of a real input signal mixed down to baseband is −6.05 dB. For this reason, it is recommended that the user compensate for this loss by enabling the 6 dB of gain in the gain stage of the DDC to recenter the dynamic range of the signal within the full scale of the output bits (see the DDC Gain Stage (Optional) section).

When mixing a complex input signal (where I and Q DDC inputs come from the different ADCs) down to baseband, the maximum value each I/Q sample is able to reach is 1.414 × full scale, after the sample passes through the complex mixer. To avoid overrange of the I/Q samples and to keep the data bit widths aligned with real mixing, −3.06 dB of loss is introduced in the mixer for complex signals. An additional −0.05 dB of loss is introduced by the NCO. The total loss of a complex input signal mixed down to baseband is −3.11 dB.

The worst case spurious signal from the NCO is greater than 102 dBc SFDR for all output frequencies.

DDC DECIMATION FILTERS

After the frequency translation stage, there are multiple decimation filter stages that reduce the output data rate. After the carrier of interest is tuned down to dc (carrier frequency = 0 Hz), these filters efficiently lower the sample rate, while providing sufficient alias rejection from unwanted adjacent carriers around the bandwidth of interest.

Figure 93 shows a simplified block diagram of the decimation filter stage, and Table 16 describes the filter characteristics of the different finite impulse response (FIR) filter blocks.

Table 17 and Table 18 show the different filter configurations selectable by including different filters. In all cases, the DDC filtering stage provides 80% of the available output bandwidth, <±0.005 dB of passband ripple and >100 dB of stop band alias rejection.
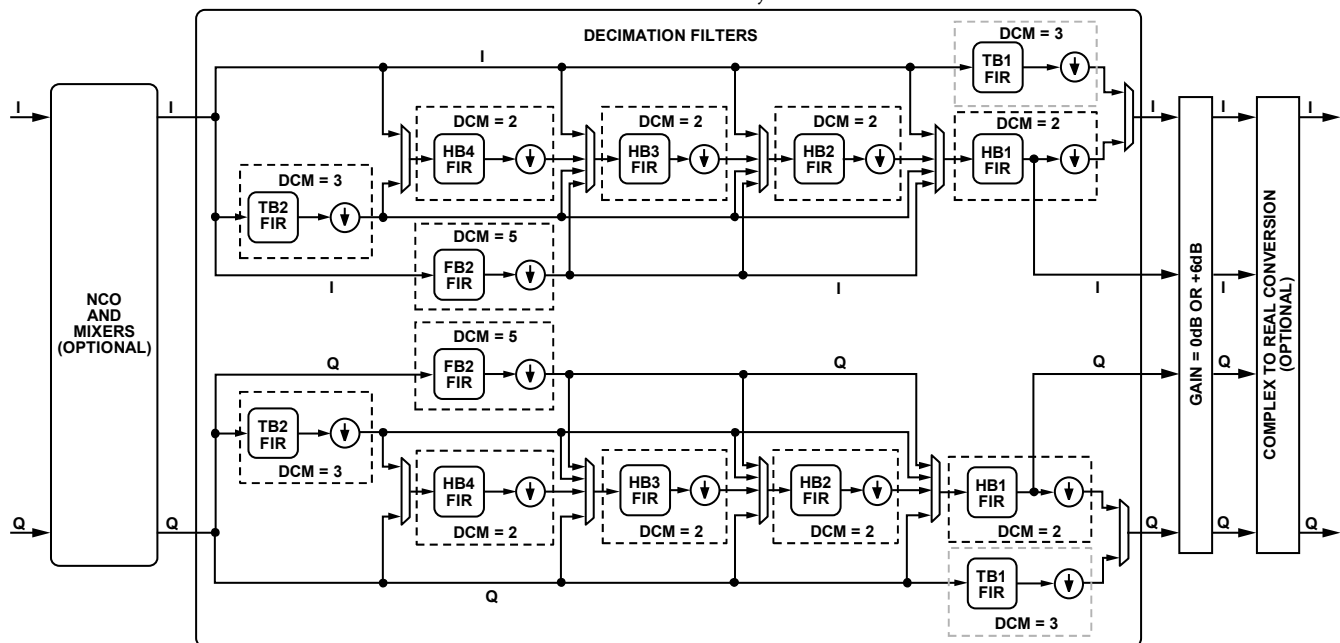

FIR = FINITE IMPULSE RESPONSE FILTER
DCM = DECIMATION

NOTES
1. TB1 IS ONLY SUPPORTED IN DDC0 AND DDC1

Figure 93. DDC Decimation Filter Block Diagram

Table 16. DDC Decimation Filter Characteristics

Filter Name	Filter Type	Decimation Ratio	Pass Band (rad/sec)	Stop Band (rad/sec)	Pass-Band Ripple (dB)	Stop-Band Attenuation (dB)
HB4	FIR low-pass	2	0.1 x π/2	1.9 x π/2	<±0.001	>100
HB3	FIR low-pass	2	0.2 x π/2	1.8 x π/2	<±0.001	>100
HB2	FIR low-pass	2	0.4 x π/2	1.6 x π/2	<±0.001	>100
HB1	FIR low-pass	2	0.8 x π/2	1.2 x π/2	<±0.001	>100
TB2	FIR low-pass	3	0.4 x π/3	1.6 x π/3	<±0.002	>100

[1] N/A means not applicable.
[2] TB1 is only supported in in DDC0 and DDC1.

HB4 Filter Description

The first decimate by 2, half-band, low-pass, FIR filter (HB4) uses an 11-tap, symmetrical, fixed coefficient filter implementation that is optimized for low power consumption. The HB4 filter is only used when complex outputs (decimate by 16) or real outputs (decimate by 8) are enabled; otherwise, it is bypassed. Table 19 and Figure 94 show the coefficients and response of the HB4 filter.

Table 19. HB4 Filter Coefficients

HB4 Coefficient Number	Normalized Coefficient	Decimal Coefficient (15-Bit)
C1, C11	0.006042	99
C2, C10	0	0
C3, C9	−0.049377	−809
C4, C8	0	0
C5, C7	0.293304	4806
C6	0.5	8192
Figure 94. HB4 Filter Response

HB3 Filter Description

The second decimate by 2, half-band, low-pass, FIR filter (HB3) uses an 11-tap, symmetrical, fixed coefficient filter implementation that is optimized for low power consumption. The HB3 filter is only used when complex outputs (decimate by 8 or 16) or real outputs (decimate by 4 or 8) are enabled; otherwise, it is bypassed. Table 20 and Figure 95 show the coefficients and response of the HB3 filter.

Table 20. HB3 Filter Coefficients

Figure 95. HB3 Filter Response

HB2 Filter Description

The third decimate by 2, half-band, low-pass, FIR filter (HB2) uses a 19-tap, symmetrical, fixed coefficient filter implementation that is optimized for low power consumption.

The HB2 filter is only used when complex or real outputs (decimate by 4, 8, or 16) is enabled; otherwise, it is bypassed.

Table 21 and Figure 96 show the coefficients and response of the HB2 filter.

Table 21. HB2 Filter Coefficients

HB1 Filter Description

The fourth and final decimate by 2, half-band, low-pass, FIR filter (HB1) uses a 63-tap, symmetrical, fixed coefficient filter implementation that is optimized for low power consumption. The HB1 filter is always enabled and cannot be bypassed. Table 22 and Figure 97 show the coefficients and response of the HB1 filter.

Figure 100. FB2 Filter Response

DDC GAIN STAGE

Each DDC contains an independently controlled gain stage. The gain is selectable as either 0 dB or 6 dB. When mixing a real input signal down to baseband, it is recommended that the user enable the 6 dB of gain to recenter the dynamic range of the signal within the full scale of the output bits.

When mixing a complex input signal down to baseband, the mixer has already recentered the dynamic range of the signal within the full scale of the output bits, and no additional gain is necessary. However, the optional 6 dB gain compensates for low signal strengths. The downsample by 2 portion of the HB1 FIR filter is bypassed when using the complex to real conversion stage. The TB1 filter does not have the 6 dB gain stage.

DDC COMPLEX TO REAL CONVERSION

Each DDC contains an independently controlled complex to real conversion block. The complex to real conversion block reuses the last filter (HB1 FIR) in the filtering stage along with an $f_S/4$ complex mixer to upconvert the signal. After upconverting the signal, the Q portion of the complex mixer is no longer needed and is dropped. The TB1 filter does not support complex to real conversion.

Figure 101 shows a simplified block diagram of the complex to real conversion.
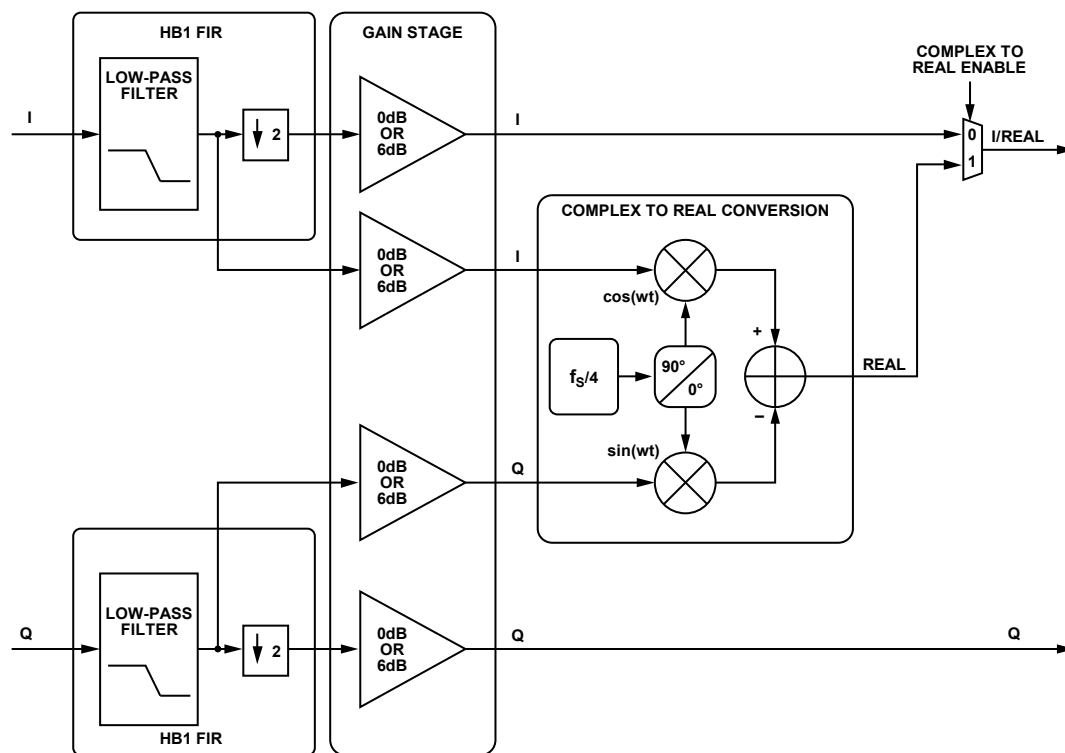

Figure 101. Complex to Real Conversion Block

DDC MIXED DECIMATION SETTINGS

The AD9208 also supports DDCs with different decimation rates. In this scenario, the chip decimation ratio must be set to the lowest decimation ratio of all the DDC channels. Samples of higher decimation ratio DDCs are repeated to match the chip decimation ratio sample rate. Only mixed decimation ratios that are integer multiples of 2 are supported. For example, decimate by 1, 2, 4, 8, or 16 can be mixed together; decimate by 3, 6, 12, 24, or 48 can be mixed together; or decimate by 5, 10, 20, or 40 can be mixed together.

Table 26 shows the DDC sample mapping when the chip decimation ratio is different than the DDC decimation ratio.

For example, if the chip decimation ratio is set to decimate by 4, DDC0 is set to use the HB2 + HB1 filters (complex outputs are decimate by 4) and DDC1 is set to use the HB4 + HB3 + HB2 + HB1 filters (real outputs are decimate by 8), then DDC1 repeats its output data two times for every one DDC0 output. The resulting output samples are shown in Table 27.

Table 26. Sample Mapping when the Chip Decimation Ratio (DCM) Does Not Match DDC DCM

Sample Index	DDC DCM = Chip DCM	DDC DCM = 2 × Chip DCM	DDC DCM = 4 × Chip DCM	DDC DCM = 8 × Chip DCM

SIGNAL MONITOR

The signal monitor block provides additional information about the signal being digitized by the ADC. The signal monitor computes the peak magnitude of the digitized signal. This information can be used to drive an AGC loop to optimize the range of the ADC in the presence of real-world signals.

The results of the signal monitor block can be obtained either by reading back the internal values from the SPI port or by embedding the signal monitoring information into the JESD204B interface as separate control bits. A global, 24-bit programmable period controls the duration of the measurement. Figure 102 shows the simplified block diagram of the signal monitor block.
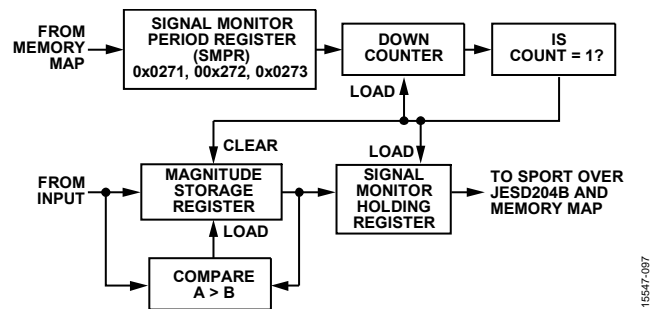

Figure 102. Signal Monitor Block

The peak detector captures the largest signal within the observation period. The detector only observes the magnitude of the signal. The resolution of the peak detector is a 13-bit value, and the observation period is 24 bits and represents converter output samples. The peak magnitude can be derived by using the following equation:

$$Peak\ Magnitude\ (dBFS) = 20log(Peak\ Detector\ Value/2^{13})$$

The magnitude of the input port signal is monitored over a programmable time period, which is determined by the signal monitor period register (SMPR). The peak detector function is enabled by setting Bit 1 in the signal monitor control register (Register 0x0270). The 24-bit SMPR must be programmed before activating this mode.

After enabling peak detection mode, the value in the SMPR is loaded into a monitor period timer, which decrements at the decimated clock rate. The magnitude of the input signal is compared with the value in the internal magnitude storage register (not accessible to the user), and the greater of the two is updated as the current peak level. The initial value of the magnitude storage register is set to the current ADC input signal magnitude. This comparison continues until the monitor period timer reaches a count of 1.

When the monitor period timer reaches a count of 1, the 13-bit peak level value is transferred to the signal monitor holding register, which can be read through the memory map or output through the SPORT over the JESD204B interface. The monitor period timer is reloaded with the value in the SMPR, and the countdown restarts. In addition, the magnitude of the first input sample is updated in the magnitude storage register, and the comparison and update procedure, as explained previously, continues.

SPORT OVER JESD204B

The signal monitor data can also be serialized and sent over the JESD204B interface as control bits. These control bits must be deserialized from the samples to reconstruct the statistical data. The signal control monitor function is enabled by setting Bits[1:0] of Register 0x0279 and Bit 1 of Register 0x027A. Figure 103 shows two different example configurations for the signal monitor control bit locations inside the JESD204B samples. A maximum of three control bits can be inserted into the JESD204B samples; however, only one control bit is required for the signal monitor. Control bits are inserted from MSB to LSB. If only one control bit

is to be inserted (CS = 1), only the most significant control bit is used (see Example Configuration 1 and Example Configuration 2 in Figure 103). To select the SPORT over JESD204B option, program Register 0x0559, Register 0x055A, and Register 0x058F. See Table 46 for more information on setting these bits.

Figure 104 shows the 25-bit frame data that encapsulates the peak detector value. The frame data is transmitted MSB first with five 5-bit subframes. Each subframe contains a start bit that can be used by a receiver to validate the deserialized data. Figure 105 shows the SPORT over JESD204B signal monitor data with a monitor period timer set to 80 samples.

DIGITAL OUTPUTS

INTRODUCTION TO THE JESD204B INTERFACE

The AD9208 digital outputs are designed to the JEDEC standard JESD204B, serial interface for data converters. JESD204B is a protocol to link the AD9208 to a digital processing device over a serial interface with lane rates of up to 16 Gbps. The benefits of the JESD204B interface over LVDS include a reduction in required board area for data interface routing and an ability to enable smaller packages for converter and logic devices.

JESD204B OVERVIEW

The JESD204B data transmit block assembles the parallel data from the ADC into frames and uses 8-bit/10-bit encoding as well as optional scrambling to form serial output data. Lane synchronization is supported through the use of separate control characters during the initial establishment of the link. Additional control characters are embedded in the data stream to maintain synchronization thereafter. A JESD204B receiver is required to complete the serial link. For additional details on the JESD204B interface, refer to the JESD204B standard.

The AD9208 JESD204B data transmit block maps up to two physical ADCs or up to eight virtual converters (when DDCs are enabled) over a link. A link can be configured to use one, two, four, or eight JESD204B lanes. The JESD204B specification refers to a number of parameters to define the link, and these parameters must match between the JESD204B transmitter (the AD9208 output) and the JESD204B receiver (the logic device input).

The JESD204B link is described according to the following parameters:

- L is the number of lanes per converter device (lanes per link); AD9208 value = 1, 2, 4, or 8.
- M is the number of converters per converter device (virtual converters per link); AD9208 value = 1, 2, 4, or 8.
- F is the octets per frame; AD9208 value = 1, 2, 4, 8, or 16.
- N′ is the number of bits per sample (JESD204B word size); AD9208 value = 8 or 16.
- N is the converter resolution; AD9208 value = 7 to 16.
- CS is the number of control bits per sample; AD9208 value = 0, 1, 2, or 3.

- K is the number of frames per multiframe; AD9208 value = 4, 8, 12, 16, 20, 24, 28, or 32.
- S is the samples transmitted per single converter per frame cycle; AD9208 value is set automatically based on L, M, F, and N′.
- HD is the high density mode; the AD9208 mode is set automatically based on L, M, F, and N′.
- CF is the number of control words per frame clock cycle per converter device; AD9208 value = 0.

Figure 106 shows a simplified block diagram of the AD9208 JESD204B link. By default, the AD9208 is configured to use two converters and four lanes. Converter A data is output to SERDOUT0± and/or SERDOUT1±, and Converter B is output to SERDOUT2± and/or SERDOUT3±. The AD9208 allows other configurations such as combining the outputs of both converters onto a single lane, or changing the mapping of the A and B digital output paths. These modes are set up via a quick configuration register in the SPI register map, along with additional customizable options.

By default in the AD9208, the 14-bit converter word from each converter is broken into two octets (eight bits of data). Bit 13 (MSB) through Bit 6 are in the first octet. The second octet contains Bit 5 through Bit 0 (LSB) and two tail bits. The tail bits can be configured as zeros or as a pseudorandom number sequence. The tail bits can also be replaced with control bits indicating overrange, SYSREF±, or fast detect output.

The two resulting octets can be scrambled. Scrambling is optional; however, it is recommended to avoid spectral peaks when transmitting similar digital data patterns. The scrambler uses a self synchronizing, polynomial-based algorithm defined by the equation $1 + x^{14} + x^{15}$. The descrambler in the receiver is a self synchronizing version of the scrambler polynomial.

The two octets are then encoded with an 8-bit/10-bit encoder. The 8-bit/10-bit encoder works by taking eight bits of data (an octet) and encoding them into a 10-bit symbol. Figure 107 shows how the 14-bit data is taken from the ADC, how the tail bits are added, how the two octets are scrambled, and how the octets are encoded into two 10-bit symbols. Figure 107 shows the default data format.

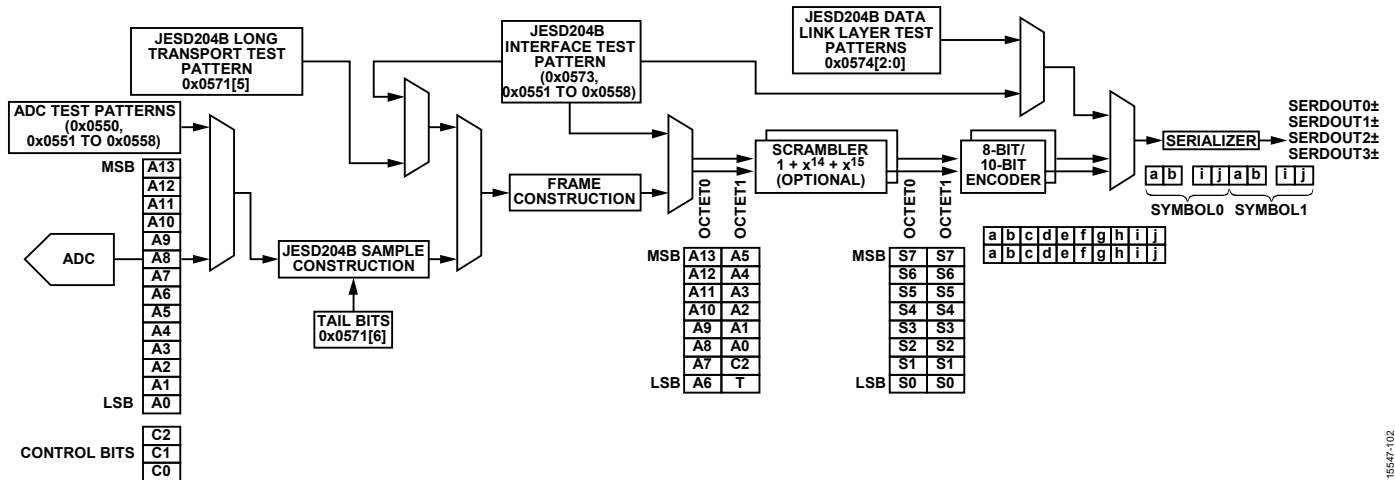

Figure 107. ADC Output Datapath Showing Data Framing
Figure 108. Data Flow

FUNCTIONAL OVERVIEW

The block diagram in Figure 108 shows the flow of data through the JESD204B hardware from the sample input to the physical output. The processing can be divided into layers that are derived from the open source initiative (OSI) model widely used to describe the abstraction layers of communications systems. These layers are the transport layer, data link layer, and physical layer (serializer and output driver).

Transport Layer

The transport layer handles packing the data (consisting of samples and optional control bits) into JESD204B frames that are mapped to 8-bit octets. These octets are sent to the data link layer. The transport layer mapping is controlled by rules derived from the link parameters. Tail bits are added to fill gaps where required. The following equation can be used to determine the number of tail bits within a sample (JESD204B word):

$$T = N' - N - CS$$

Data Link Layer

The data link layer is responsible for the low level functions of passing data across the link. These functions include optionally scrambling the data, inserting control characters for multichip synchronization/lane alignment/monitoring, and encoding 8-bit octets into 10-bit symbols. The data link layer is also responsible for sending the initial lane alignment sequence (ILAS), which contains the link configuration data used by the receiver to verify the settings in the transport layer.

Physical Layer

The physical layer consists of the high speed circuitry clocked at the serial clock rate. In this layer, parallel data is converted into one, two, or four lanes of high speed differential serial data.

JESD204B LINK ESTABLISHMENT

The AD9208 JESD204B transmitter (Tx) interface operates in Subclass 1 as defined in the JEDEC Standard 204B (July 2011 specification). The link establishment process is divided into the following steps: code group synchronization and SYNCINB±, initial lane alignment sequence, and user data and error correction.

Code Group Synchronization (CGS) and SYNCINB±

The CGS is the process by which the JESD204B receiver finds the boundaries between the 10-bit symbols in the stream of data. During the CGS phase, the JESD204B transmit block transmits /K28.5/ characters. The receiver must locate /K28.5/ characters in its input data stream using clock and data recovery (CDR) techniques.

The receiver issues a synchronization request by asserting the SYNCINB± pin of the AD9208 low. The JESD204B Tx then begins sending /K/ characters. After the receiver synchronizes, it waits for the correct reception of at least four consecutive /K/ symbols. It then deasserts SYNCINB±. The AD9208 then transmits an ILAS on the following LMFC boundary.

For more information on the code group synchronization phase, refer to the JEDEC Standard JESD204B, July 2011, Section 5.3.3.1.

The SYNCINB± pin operation can also be controlled by the SPI. The SYNCINB± signal is a differential dc-coupled LVDS mode signal by default, but it can also be driven single-ended. For more information on configuring the SYNCINB± pin operation, refer to Register 0x0572.

The SYNCINB± pins can also be configured to run in CMOS (single-ended) mode, by setting Bit 4 in Register 0x0572. When running SYNCINB± in CMOS mode, connect the CMOS SYNCINB signal to Pin N13 (SYNCINB+) and leave Pin R13 (SYNCINB−) floating.

Initial Lane Alignment Sequence (ILAS)

The ILAS phase follows the CGS phase and begins on the next LMFC boundary. The ILAS consists of four multiframes, with an /R/ character marking the beginning and an /A/ character marking the end. The ILAS begins by sending an /R/ character followed by 0 to 255 ramp data for one multiframe. On the second multiframe, the link configuration data is sent, starting with the third character. The second character is a /Q/ character to confirm that the link configuration data is to follow. All undefined data slots are filled with ramp data. The ILAS sequence is never scrambled.

The ILAS sequence construction is shown in Figure 109. The four multiframes include the following:

- Multiframe 1 begins with an /R/ character (/K28.0/) and ends with an /A/ character (/K28.3/).
- Multiframe 2 begins with an /R/ character followed by a /Q/ character (/K28.4/), followed by link configuration parameters over 14 configuration octets (see Table 30) and ends with an /A/ character. Many of the parameter values are of the value − 1 notation.
- Multiframe 3 begins with an /R/ character (/K28.0/) and ends with an /A/ character (/K28.3/).
- Multiframe 4 begins with an /R/ character (/K28.0/) and ends with an /A/ character (/K28.3/).

User Data and Error Detection

After the initial lane alignment sequence is complete, the user data is sent. Normally, within a frame, all characters are considered user data. However, to monitor the frame clock and multiframe clock synchronization, there is a mechanism for replacing characters with /F/ or /A/ alignment characters when the data meets certain conditions. These conditions are different for unscrambled and scrambled data. The scrambling operation is enabled by default; however, it can be disabled using the SPI.

For scrambled data, any 0xFC character at the end of a frame is replaced by an /F/, and any 0x7C character at the end of a multiframe is replaced by an /A/. The JESD204B receiver (Rx) checks for /F/ and /A/ characters in the received data stream and verifies that they only occur in the expected locations. If an unexpected /F/ or /A/ character is found, the receiver handles the situation by using dynamic realignment or asserting the SYNCINB± signal for more than four frames to initiate a resynchronization. For unscrambled data, if the final character of two subsequent frames is equal, the second character is replaced with an /F/ if it is at the end of a frame, and an /A/ if it is at the end of a multiframe.

Insertion of alignment characters can be modified using the SPI. The frame alignment character insertion (FACI) is enabled by default. More information on the link controls is available in the Memory Map section, Register 0x0571.

8-Bit/10-Bit Encoder

The 8-bit/10-bit encoder converts 8-bit octets into 10-bit symbols and inserts control characters into the stream when needed. The control characters used in JESD204B are shown in Table 30. The 8-bit/10-bit encoding ensures that the signal is dc balanced by using the same number of ones and zeros across multiple symbols.

The 8-bit/10-bit interface has options that can be controlled via the SPI. These operations include bypass and invert. These options are troubleshooting tools for the verification of the digital front end (DFE). See the Memory Map section, Register 0x0572, Bits[2:1] for information on configuring the 8-bit/10-bit encoder.

Figure 109. Initial Lane Alignment Sequence

Table 30. AD9208 Control Characters used in JESD204B

Abbreviation	Control Symbol	8-Bit Value	10-Bit Value, RD[1] = −1	10-Bit Value, RD[1] = +1	Description
/R/	/K28.0/	000 11100	001111 0100	110000 1011	Start of multiframe
/A/	/K28.3/	011 11100	001111 0011	110000 1100	Lane alignment

[1] RD means running disparity.

Figure 110. AC-Coupled Digital Output Termination Example

PHYSICAL LAYER (DRIVER) OUTPUTS

Digital Outputs, Timing, and Controls

The AD9208 physical layer consists of drivers that are defined in the JEDEC Standard JESD204B, July 2011. The differential digital outputs are powered up by default. The drivers use a dynamic 100 Ω internal termination to reduce unwanted reflections.

Place a 100 Ω differential termination resistor at each receiver input to result in a nominal 0.85 × DRVDD1 V p-p swing at the receiver (see Figure 110). The swing is adjustable through the SPI registers. AC coupling is recommended to connect to the receiver. See the Memory Map section (Register 0x05C0 to Register 0x05C3 in Table 46) for more details.

The AD9208 digital outputs can interface with custom ASICs and field programmable gate array (FPGA) receivers, providing superior switching performance in noisy environments. Single point-to-point network topologies are recommended with a single differential 100 Ω termination resistor placed as close to the receiver inputs as possible.

If there is no far end receiver termination, or if there is poor differential trace routing, timing errors can result. To avoid such timing errors, it is recommended that the trace length be less than six inches, and that the differential output traces be close together and at equal lengths.

Figure 111 to Figure 113 show an example of the digital output data eye, jitter histogram, and bathtub curve for one AD9208 lane running at 16 Gbps. The format of the output data is twos complement by default. To change the output data format, see the Memory Map section (Register 0x0561 in Table 46).

De-Emphasis

De-emphasis enables the receiver eye diagram mask to be met in conditions where the interconnect insertion loss does not meet the JESD204B specification. Use the de-emphasis feature only when the receiver is unable to recover the clock due to excessive insertion loss. Under normal conditions, it is disabled to conserve power. Additionally, enabling and setting too high a de-emphasis value on a short link can cause the receiver eye diagram to fail. Use the de-emphasis setting with caution because it can increase electromagnetic interference (EMI). See the Memory Map section (Register 0x05C4 to Register 0x05CB in Table 46) for more details.

Phase-Locked Loop (PLL)

The PLL generates the serializer clock, which operates at the JESD204B lane rate. The status of the PLL lock can be checked in the PLL locked status bit (Register 0x056F, Bit 7). This read only bit notifies the user if the PLL achieved a lock for the specific setup. Register 0x056F also has a loss of lock (LOL) sticky bit (Bit 3) that notifies the user that a loss of lock is detected. The sticky bit can be reset by issuing a JESD204B link restart (Register 0x0571 = 0x15, followed by Register 0x0571 = 0x14). Refer to Table 32 for the reinitialization of the link following a link power cycle.

The JESD204B lane rate control, Bits[7:4] of Register 0x056E, must be set to correspond with the lane rate. Table 31 shows the lane rates supported by the AD9208 using Register 0x056E.

Table 31. AD9208 Register 0x056E Supported Lane Rates

Value	Lane Rate
0x00	Lane rate = 6.75 Gbps to 13.5 Gbps
0x10	Lane rate = 3.375 Gbps to 6.75 Gbps
0x30	Lane rate = 13.5 Gbps to 15.5 Gbps (default for AD9208)
0x50	Lane rate = 1.6875 Gbps to 3.375 Gbps

f$_S$ × 4 MODE

f$_S$ × 4 mode adds a separate packing mode on top of a JESD204B transmitter/receiver to fix the serial lane rate at four times the sample rate (f$_S$).

The JESD204B link settings are

- L = 8
- M = 2
- F = 2
- S = 5
- N' = 12
- N = 12
- CS = 0
- CF = 2
- HD = 1

However, CF = 2 is not supported by the design; therefore, the following link parameters are used along with separate packing:

- L = 8
- M = 2
- F = 2
- S = 4
- N' = 16
- N = 16
- CS = 0
- CF = 0
- HD = 0

In f$_S$ × 4 mode, five 12-bit ADC samples (along with an extra 4 bits) are packed into four 16-bit JESD204B samples to create a 64-bit frame.

The following SPI writes are necessary to place the device in f$_S$ × 4 mode:

- Register 0x0570 = 0xFE. This setting places the device in M = 2, L = 8, f$_S$ × 4 mode.
- Register 0x058B = 0x0F. This setting places the device CS = 0, N' = 16 mode.
- Register 0x058F = 0x2F. This setting places the device in Subclass 1 mode, N = 16.

The transmit architecture of f$_S$ × 4 mode is shown in Figure 114 and the receive portion is shown in Figure 115. f$_S$ × 4 mode only works in full bandwidth mode (Register 0x0200 = 0x00).
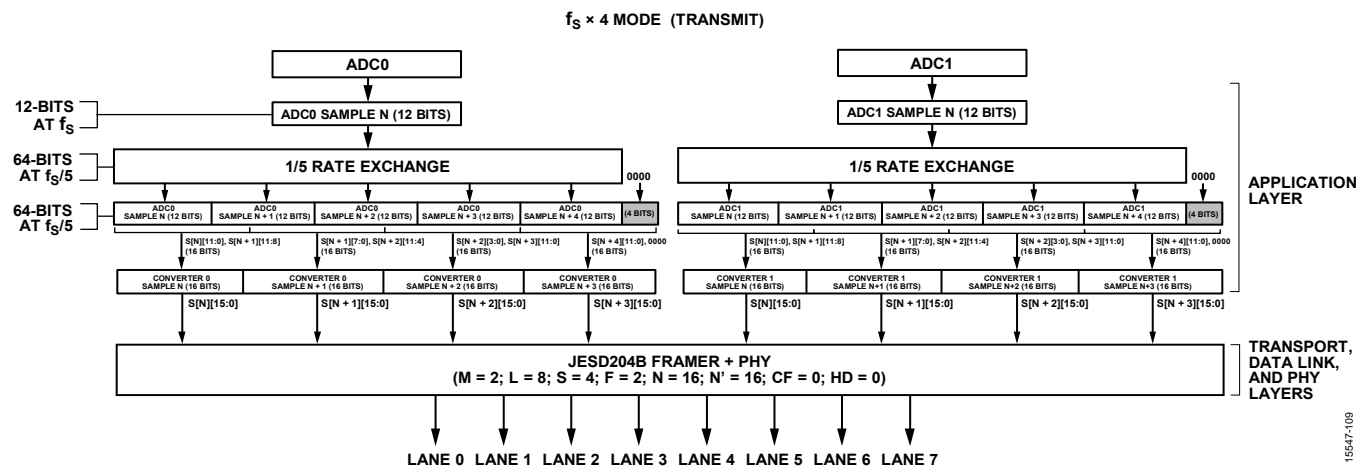

Figure 114. f$_S$ × 4 Mode (Transmit)
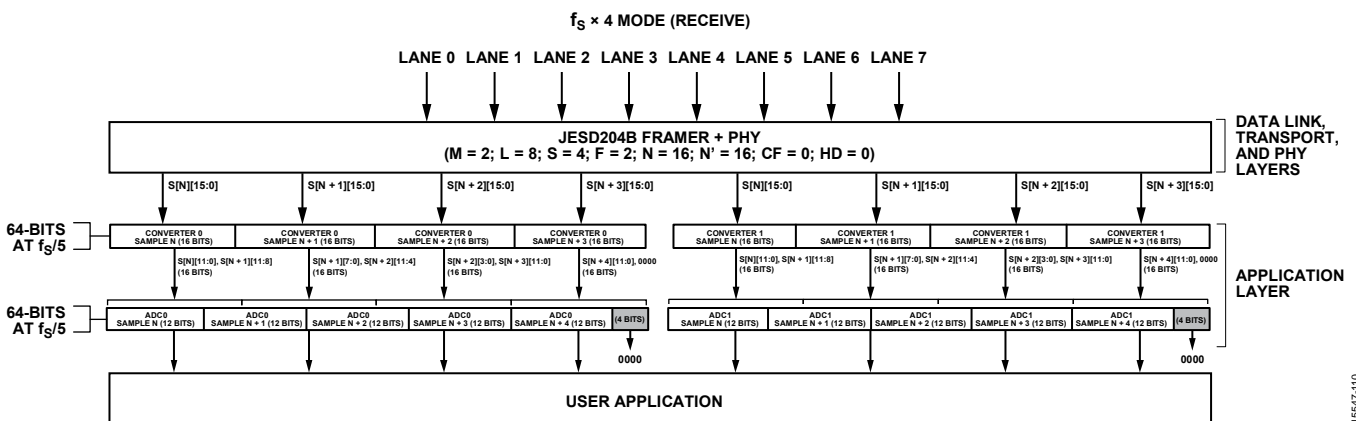

Figure 115. f$_S$ × 4 Mode (Receive)

SETTING UP THE AD9208 DIGITAL INTERFACE

To ensure proper operation of the AD9208 at startup, some SPI writes are required to initialize the link. Additionally, these registers must be written every time the ADC is reset. Any one of the following resets warrants the initialization routine for the digital interface:

- Hard reset, as with power-up.
- Power-up using the PDWN pin.
- Power-up using the SPI via Register 0x0002, Bits[1:0].
- SPI soft reset by setting Register 0x0000 = 0x81.
- Datapath soft reset by setting Register 0x0001 = 0x02.
- JESD204B link power cycle by setting Register 0x0571 = 0x15, then 0x14.

The initialization SPI writes are as shown in Table 32.

Table 32. AD9208 JESD204B Initialization

Register	Value	Comment
0x1228	0x4F	Reset JESD204B start-up circuit
0x1228	0x0F	JESD204B start-up circuit in normal operation
0x1222	0x00	JESD204B PLL force normal operation
0x1222	0x04	Reset JESD204B PLL calibration
0x1222	0x00	JESD204B PLL normal operation
0x1262	0x08	Clear loss of lock bit
0x1262	0x00	Loss of lock bit normal operation

The AD9208 has one JESD204B link. The serial outputs (SERDOUT0± to SERDOUT7±) are considered to be part of one JESD204B link. The basic parameters that determine the link setup are

- Number of lanes per link (L)
- Number of converters per link (M)
- Number of octets per frame (F)

If the internal DDCs are used for on-chip digital processing, M represents the number of virtual converters. The virtual converter mapping setup is shown in Figure 77.

The maximum lane rate allowed by the AD9208 is 16 Gbps. The lane rate is related to the JESD204B parameters using the following equation:

$$Lane\ Rate = \frac{M \times N' \times \left(\frac{10}{8}\right) \times f_{OUT}}{L}$$

where $f_{OUT} = \dfrac{f_{ADC\_CLOCK}}{Decimation\ Ratio}$

The decimation ratio (DCM) is the parameter programmed in Register 0x201.

Use the following procedure to configure the output:

1. Power down the link.
2. Select the JESD204B link configuration options.
3. Configure the detailed options.
4. Set output lane mapping (optional).
5. Set additional driver configuration options (optional).
6. Power up the link.
7. Initialize the JESD204B link by issuing the commands described in Table 32.

If the lane rate calculated is less than 6.25 Gbps, select the low lane rate option by programming a value of 0x10 to Register 0x056E.

Table 33 and Table 34 show the JESD204B output configurations supported for both N′ = 16 and N′ = 8 for a given number of virtual converters. Take care to ensure that the serial lane rate for a given configuration is within the supported range of 3.4 Gbps to 16 Gbps.

Table 33. JESD204B Output Configurations for N′ = 16[1]

[1] Due to the internal clock requirements, only certain decimation rates are supported for certain link parameters.

[2] JESD204B transport layer descriptions are as follows: L is the number of lanes per converter device (lanes per link); M is the number of virtual converters per converter device (virtual converters per link); F is the octets per frame; S is the samples transmitted per virtual converter per frame cycle; HD is the high density mode; N is the virtual converter resolution (in bits); N' is the total number of bits per sample (JESD204B word size); CS is the number of control bits per conversion sample; K is the number of frames per multiframe.

[3] f_{ADC_CLK} is the ADC sample rate; DCM = chip decimation ratio; f_{OUT} is the output sample rate = f_{ADC_CLK}/DCM; SLR is the JESD204B serial lane rate. The following equations must be met due to internal clock divider requirements: SLR ≥ 1.6875 Gbps and SLR ≤ 15.5 Gbps; SLR/40 ≤ f_{ADC_CLK}; least common multiple (20 × DCM × f_{OUT}/SLR, DCM) ≤ 64. When the SLR is ≤ 15500 Mbps and > 13500 Mbps, Register 0x056E must be set to 0x30. When the SLR is ≤ 13500 Mbps and ≥ 6750 Mbps, Register 0x056E must be set to 0x00. When the SLR is < 6750 Mbps and ≥ 3375 Mbps, Register 0x056E must be set to 0x10. When the SLR is < 3375 Mbps and ≥ 1687.5 Mbps, Register 0x056E must be set to 0x50.

[4] Only valid K × F values that are divisible by 4 are supported: for F = 1, K = 20, 24, 28, 32; for F = 2, K = 12, 16, 20, 24, 28, 32; for F = 4, K = 8, 12, 16, 20, 24, 28, 32; for F = 8, K = 4, 8, 12, 16, 20, 24, 28, 32; and for F = 16, K = 4, 8, 12, 16, 20, 24, 28, 32.

[1] Due to the internal clock requirements, only certain decimation rates are supported for certain link parameters.

[2] f_{ADC_CLK} is the ADC sample rate; DCM is the chip decimation ratio; f_{OUT} is the output sample rate = f_{ADC_CLK}/DCM; SLR is the JESD204B serial lane rate. The following equations must be met due to internal clock divider requirements: SLR ≥ 1.6875 Gbps and SLR ≤ 15.5 Gbps; SLR/40 ≤ f_{ADC_CLK}; least common multiple (20 × DCM × f_{OUT}/SLR, DCM) ≤ 64. When the SLR is ≤ 15500 Mbps and > 13500 Mbps, Register 0x056E must be set to 0x30. When the SLR is ≤ 13500 Mbps and ≥ 6750 Mbps, Register 0x056E must be set to 0x00. When the SLR is < 6750 Mbps and ≥ 3375 Mbps, Register 0x056E must be set to 0x10. When the SLR is < 3375 Mbps and ≥ 1687.5 Mbps, Register 0x056E must be set to 0x50.

[3] JESD204B transport layer descriptions are as follows: L is the number of lanes per converter device (lanes per link); M is the number of virtual converters per converter device (virtual converters per link); F is the octets per frame; S is the samples transmitted per virtual converter per frame cycle; HD is the high density mode; N is the virtual converter resolution (in bits); N' is the total number of bits per sample (JESD204B word size); CS is the number of control bits per conversion sample; K is the number of frames per multiframe.

[4] Only valid K × F values that are divisible by 4 are supported: for F = 1, K = 20, 24, 28, 32; for F = 2, K = 12, 16, 20, 24, 28, 32; for F = 4, K = 8, 12, 16, 20, 24, 28, 32; for F = 8, K = 4, 8, 12, 16, 20, 24, 28, 32; and for F = 16, K = 4, 8, 12, 16, 20, 24, 28, 32.

[1] Due to the internal clock requirements, only certain decimation rates are supported for certain link parameters.

[2] f_{ADC_CLK} is the ADC sample rate; DCM is the chip decimation ratio; f_{OUT} is the output sample rate = f_{ADC_CLK}/DCM; SLR is the JESD204B serial lane rate. The following equations must be met due to internal clock divider requirements: SLR ≥ 1.6875 Gbps and SLR ≤ 15.5 Gbps; SLR/40 ≤ f_{ADC_CLK}; least common multiple (20 × DCM × f_{OUT}/SLR, DCM) ≤ 64. When the SLR is ≤ 15500 Mbps and > 13500 Mbps, Register 0x056E must be set to 0x30. When the SLR is ≤ 13500 Mbps and ≥ 6750 Mbps, Register 0x056E must be set to 0x00. When the SLR is < 6750 Mbps and ≥ 3375 Mbps, Register 0x056E must be set to 0x10. When the SLR is < 3375 Mbps and ≥ 1687.5 Mbps, Register 0x056E must be set to 0x50.

[3] JESD204B transport layer descriptions are as follows: L is the number of lanes per converter device (lanes per link); M is the number of virtual converters per converter device (virtual converters per link); F is the octets per frame; S is the samples transmitted per virtual converter per frame cycle; HD is the high density mode; N is the virtual converter resolution (in bits); N' is the total number of bits per sample (JESD204B word size); CS is the number of control bits per conversion sample; K is the number of frames per multiframe.

[4] Only valid K × F values that are divisible by 4 are supported: for F = 1, K = 20, 24, 28, 32; for F = 2, K = 12, 16, 20, 24, 28, 32; for F = 4, K = 8, 12, 16, 20, 24, 28, 32; for F = 8, K = 4, 8, 12, 16, 20, 24, 28, 32; and for F = 16, K = 4, 8, 12, 16, 20, 24, 28, 32.

Example 1—Full Bandwidth Mode

L_Y = LANE Y
S_Z = SAMPLE Z INSIDE A JESD204B FRAME
C = CONTROL BIT (OVERRANGE, AMONG OTHERS)
T = TAIL BIT

Figure 116. Full Bandwidth Mode

The AD9208 is set up as shown in Figure 116, with the following configurations:

- Two 14-bit converters at 2.94912 GSPS.
- Full bandwidth application layer mode.
- Decimation filters bypassed.

The JESD204B output configuration is as follows:

- Two virtual converters required (see Table 33).
- Output sample rate (f_{OUT}) = 2949.12/1 = 2949.12 MSPS.

The JESD204B supported output configurations are as follows (see Table 33):

- N′ = 16 bits.
- N = 14 bits.
- L = 8, M = 2, and F = 1, or L = 8, M = 2, and F = 2.
- CS = 0.
- K = 32.
- Output serial lane rate = 14.7456 Gbps per lane.
- The PLL control register, Register 0x056E, is set to 0x30.

Example 2—ADC with DDC Option (Two ADCs Plus Two DDCs)
Figure 117. Two ADCs Plus Two DDCs Mode (L = 4, M = 4, F = 2, S = 1)

This example shows the flexibility in the digital and lane configurations for the AD9208. The sample rate is 2.94912 GSPS; however, the outputs are all combined in either two or four lanes, depending on the input/output speed capability of the receiving device.

The AD9208 is set up as shown in Figure 117, with the following configuration:

- Two 14-bit converters at 2.94912 GSPS.
- Two DDC application layer mode with complex outputs (I/Q).
- Chip decimation ratio = 8.
- DDC decimation ratio = 8 (see Table 46).

The JESD204B output configuration is as follows:

- Four virtual converters required (see Table 33).
- Output sample rate (f_{OUT}) = 2949.12/8 = 368.64 MSPS.

The JESD204B supported output configurations are as follows (see Table 33):

- N′ = 16 bits.
- N = 14 bits .
- L = 2, M = 4, and F = 4, or L = 4, M = 4, and F = 2.
- CS = 0.
- K = 32.
- Output serial lane rate = 14.7456 Gbps per lane (L = 2) or 7.3728 Gbps per lane (L = 4).

For L = 2, set the PLL control register, Register 0x056E, to 0x30.
For L = 4, set the PLL control register, Register 0x056E, to 0x00.

DETERMINISTIC LATENCY

Both ends of the JESD204B link contain various clock domains distributed throughout each system. Data traversing from one clock domain to a different clock domain can lead to ambiguous delays in the JESD204B link. These ambiguities lead to non-repeatable latencies across the link from one power cycle or link reset to the next. Section 6 of the JESD204B specification addresses the issue of deterministic latency with mechanisms defined as Subclass 1 and Subclass 2.

The AD9208 supports JESD204B Subclass 0 and Subclass 1 operation. Register 0x0590, Bits[7:5] set the subclass mode for the AD9208 and its default is set for Subclass 1 operating mode (Register 0x0590, Bit 5 = 1). If deterministic latency is not a system requirement, Subclass 0 operation is recommended and the SYSREF signal may not be required. Even in Subclass 0 mode, the SYSREF signal may be required in an application where multiple AD9208 devices must be synchronized with each other. This topic is addressed in the Timestamp Mode section.

SUBCLASS 0 OPERATION

If there is no requirement for multichip synchronization while operating in Subclass 0 mode (Register 0x0590, Bits[7:5]= 0), the SYSREF input can be left disconnected. In this mode, the relationship of the JESD204B clocks between the JESD204B transmitter and receiver are arbitrary, but does not affect the ability of the receiver to capture and align the lanes within the link.

SUBCLASS 1 OPERATION

The JESD204B protocol organizes data samples into octets, frames, and multiframes as described in the Transport Layer section. The LMFC is synchronous with the beginnings of these multiframes. In Subclass 1 operation, the SYSREF is used to synchronize the LMFCs for each device in a link or across multiple links (within the AD9208, SYSREF also synchronizes the internal sample dividers), as shown in Figure 118. The JESD204B receiver uses the multiframe boundaries and buffering to achieve consistent latency across lanes (or even multiple devices), and also to achieve a fixed latency between power cycles and link reset conditions.

Deterministic Latency Requirements

Several key factors are required for achieving deterministic latency in a JESD204B Subclass 1 system.

- SYSREF± signal distribution skew within the system must be less than the desired uncertainty for the system.
- SYSREF± setup and hold time requirements must be met for each device in the system.
- The total latency variation across all lanes, links, and devices must be ≤1 LMFC periods (see Figure 118). This includes both variable delays and the variation in fixed delays from lane to lane, link to link, and device to device in the system.
Figure 118. SYSREF and LMFC

Setting Deterministic Latency Registers

The JESD204B receiver in the logic device buffers data starting on the LMFC boundary. If the total link latency in the system is near an integer multiple of the LMFC period, it is possible that from one power cycle to the next, the data arrival time at the receive buffer may straddle an LMFC boundary. To ensure deterministic latency in this case, a phase adjustment of the LMFC at either the transmitter or receiver must be performed. Typically, adjustments to accommodate the receive buffer are made to the LMFC of the receiver. Alternatively, this adjustment can be made in the AD9208 using the LMFC offset register (Register 0x0578, Bits[4:0]). This delays the LMFC in frame clock increments, depending on the F parameter (number of octets per lane per frame). For F = 1, every fourth setting (0, 4, 8, and so on) is valid and results in a four frame clock shift. For F = 2, every other setting (0, 2, 4, and so on) is valid and results in a two frame clock shift. For all other values of F, each setting results in a one frame clock shift. Figure 119 shows that, when the link latency is near an LMFC boundary, the local LMFC of the AD9208 can be adjusted to delay the data arrival time at the receiver. Figure 120 shows how the LMFC of the receiver is delayed to accommodate the receive buffer timing. Consult the applicable JESD204B receiver user guide for details on making

this adjustment. If the total latency in the system is not near an integer multiple of the LMFC period or if the appropriate adjustments have been made to the LMFC phase at the clock source, it is still possible to have variable latency from one power cycle to the next. By design, the AD9208 has circuitry in place to minimize this variation from power-up to power-up. In this case, the user must check for the possibility that the setup and hold time requirements for the SYSREF signal are not being met, by reading the SYSREF setup/hold monitor register (Register 0x0128). This function is fully described in the SYSREF± Setup/Hold Window Monitor section.

If reading Register 0x0128 indicates there may be a timing problem, there are a few adjustments that can made in the AD9208. Changing the SYSREF level that is used for alignment is possible using the SYSREF transition select bit (Register 0x0120, Bit 4). Also, changing which edge of CLK is used to capture SYSREF can be done using the CLK edge select bit (Register 0x0120, Bit 3). Both of these options are described in the SYSREF Control Features section. If neither of these measures helps to achieve an acceptable setup and hold time, adjusting the phase of SYSREF and/or the device clock (CLK±) may be required.
Figure 119. Adjusting the JESD204B Tx LMFC in the AD9208
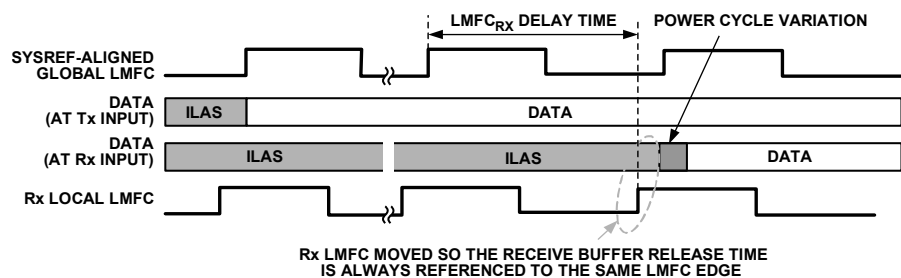

Figure 120. Adjusting the JESD204B Rx LMFC in the Logic Device

MULTICHIP SYNCHRONIZATION

The flowchart in Figure 122 shows the internal mechanism for multichip synchronization in the AD9208. There are two methods by which multichip synchronization can take place, as determined by the chip synchronization mode bit (Register 0x01FF, Bit 0). Each method involves different applications of the SYSREF signal.

NORMAL MODE

The default sate of the chip synchronization mode bit is 0, which configures the AD9208 for normal chip synchronization. The JESD204B standard specifies the use of SYSREF to provide for deterministic latency within a single link. This same concept, when applied to a system with multiple converters and logic devices can also provide multichip synchronization. In Figure 122, this is referred to as normal mode. Following the process in the flowchart ensures that the AD9208 is configured appropriately. The user must also consult the logic devices user IP guide to ensure that the JESD204B receivers are configured appropriately.

TIMESTAMP MODE

For all AD9208 full bandwidth operating modes, the SYSREF input can also be used to timestamp samples. This is another method by which multiple channels and multiple devices can achieve synchronization. This method is especially effective when synchronizing multiple devices to one or more logic devices. The logic devices buffer the data streams, identify the timestamped samples, and align them. When the chip synchronization mode bit (Register 0x01FF, Bit 0) is set to 1, the timestamp method is used for synchronization of multiple channels and/or devices. In this mode, SYSREF resets the sample dividers and the JESD204B clocking. When the chip sync mode is set to 1, the clocks are not reset; instead, the coinciding sample is timestamped using the JESD204B control bits of that sample. To operate in timestamp mode, these additional settings are necessary:

- Continuous or N-shot SYSREF must be enabled (Register 0x0120, Bits[2:1] = 1 or 2).
- At least one control bit must be enabled (Register 0x058F, Bits[7:6] = 1, 2, or 3).
- Set the function for one of the control bits to SYSREF:
  - Register 0x0559, Bits[3:0] = 5 if using Control Bit 0.
  - Register 0x0559, Bits[7:4] = 5 if using Control Bit 1.
  - Register 0x055A, Bits[3:0] = 5 if using Control Bit 2.

Figure 121 shows how the input sample coincident with SYSREF is timestamped and ultimately output of the ADC. In this example, there are two control bits, and Control Bit 0 is the bit indicating which sample was coincident with the SYSREF rising edge. Note that the pipeline latencies for each channel are identical. If so desired, the SYSREF timestamp delay register (Register 0x0123) can be used to adjust the timing of which sample is time stamped.

Note that time stamping is not supported by any AD9208 operating modes that use decimation.
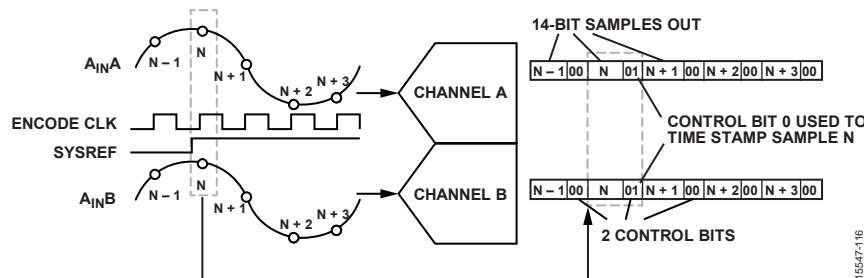

Figure 121. AD9208 Timestamping Example—CS = 2 (Register 0x058F, Bits[7:6] = 2), Control Bit 0 is SYSREF (Register 0x0559, Bits[3:0] = 5)
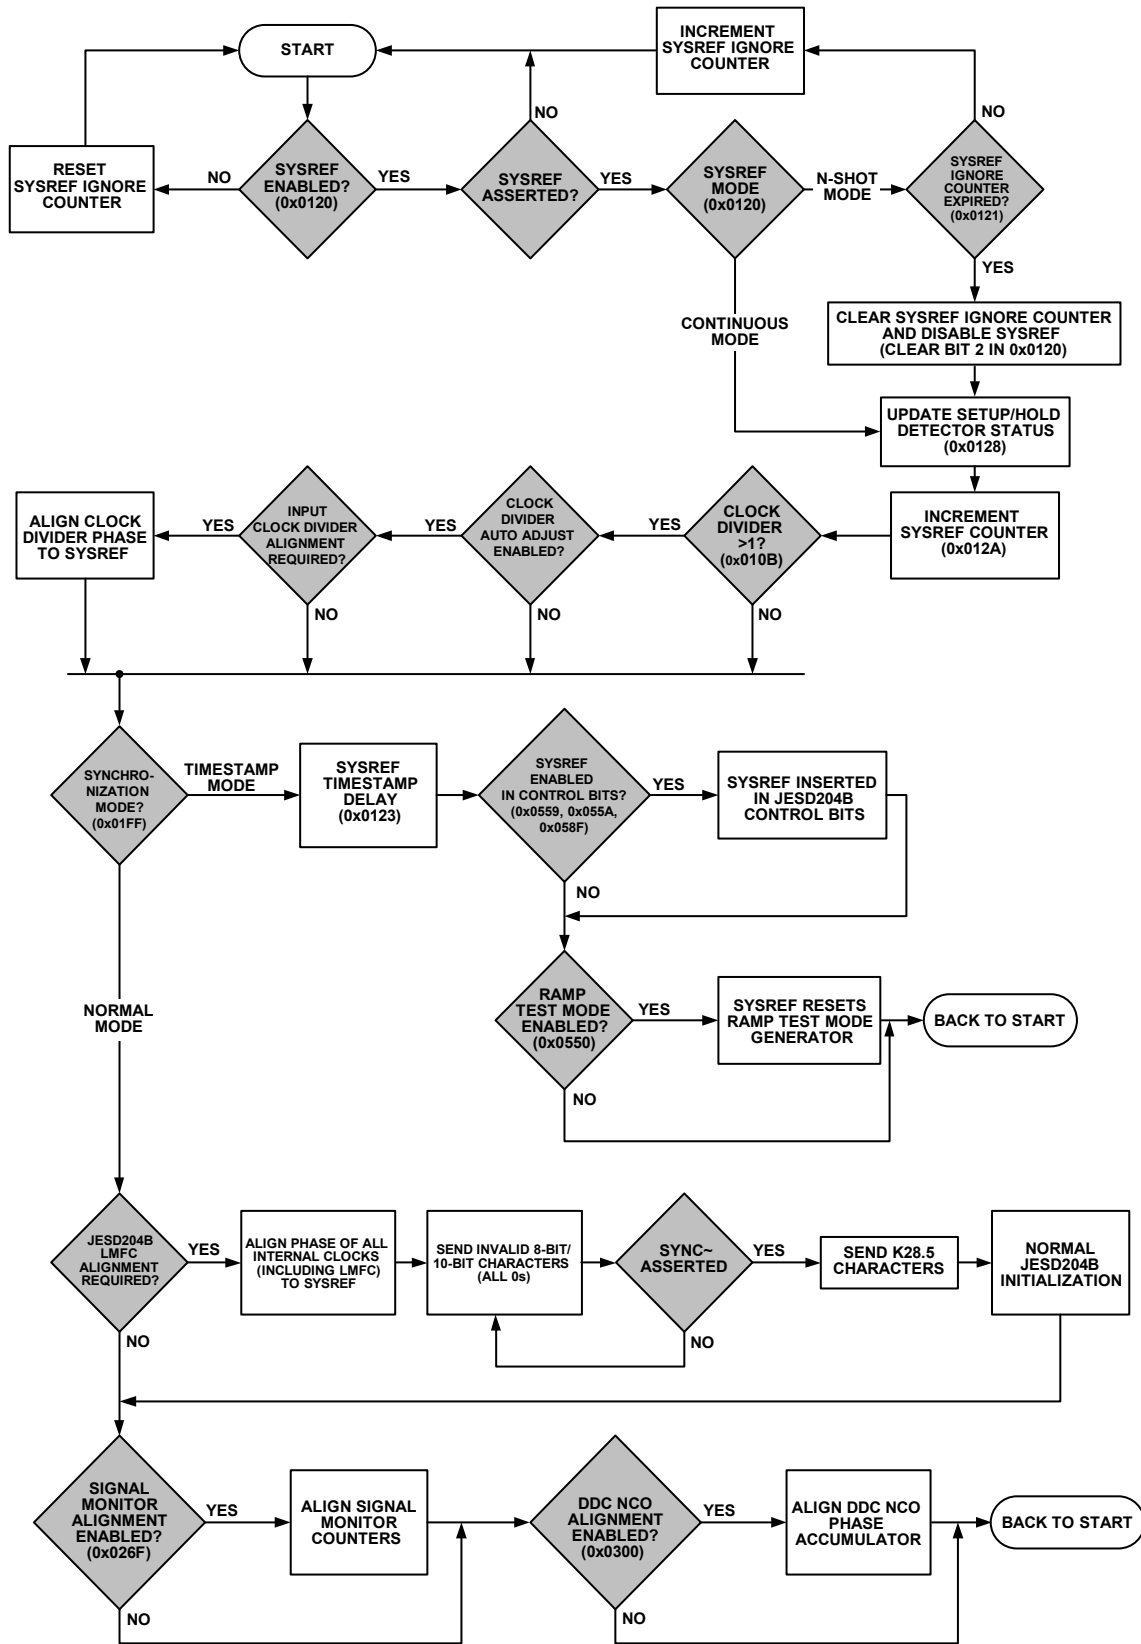

Figure 122. SYSREF Capture Scenarios and Multichip Synchronization

SYSREF INPUT

The SYSREF input signal is used as a high accuracy system reference for deterministic latency and multichip synchronization. The AD9208 accepts a single-shot or periodic input signal. The SYSREF mode select bits (Register 0x0120, Bits[2:1]) select the input signal type and also arm the SYSREF state machine when set. If in single (or N) shot mode (Register 0x0120, Bits[2:1] = 2), the SYSREF mode select bit self clears after the appropriate SYSREF transition is detected. The pulse width must have a minimum width of two CLK± periods. If the clock divider (Register 0x010B, Bits[3:0]) is set to a value other than divide by 1, multiply this minimum pulse width requirement by the divide ratio (that is, if set to divide by 8, the minimum pulse width is 16 CLK± cycles). When using a continuous SYSREF signal (Register 0x0120, Bits[2:1] = 1), the period of the SYSREF signal must be an integer multiple of the LMFC. LMFC can be derived using the following formula:

$$LMFC = ADC\ clock/(S \times K)$$

where:
S is the JESD204B parameter for number of samples per converter.
K is the number of frames per multiframe.

The input clock divider, DDCs, signal monitor block, and JESD204B link are all synchronized using the SYSREF± input when in normal synchronization mode (Register 0x01FF, Bit 0 = 0). The SYSREF± input can also be used to timestamp an ADC sample to provide a mechanism for synchronizing multiple AD9208 devices in a system. For the highest level of timing accuracy, SYSREF± must meet setup and hold requirements relative to the CLK± input. There are several features in the AD9208 that can be used to ensure these requirements are met; these features are described in the SYSREF Control Features section.

SYSREF Control Features

SYSREF is used, along with the input clock (CLK), as part of a source-synchronous timing interface and requires setup and hold timing requirements of −65 ps and 95 ps relative to the input clock (see Figure 123). The AD9208 has several features that aid users in meeting these requirements. First, the SYSREF sample event can be defined as either a synchronous low to high transition or synchronous high to low transition. Second, the AD9208 allows the SYSREF signal to be sampled using either the rising edge or falling edge of the input clock. Figure 123, Figure 124, Figure 125, and Figure 126 show all four possible combinations.

The third SYSREF related feature available is the ability to ignore a programmable number (up to 16) of SYSREF events. The AD9208 is able to ignore N SYSREF events (note that the SYSREF ignore feature is enabled by setting the SYSREF mode register (Register 0x0120, Bits[2:1]) to 2'b10, which is labeled as N-shot mode. This feature is useful for handling periodic SYSREF signals, which need time to settle after startup. Ignoring SYSREF until the clocks in the system have settled can avoid an inaccurate SYSREF trigger. Figure 127 shows an example of the SYSREF ignore feature when ignoring three SYSREF events.
Figure 123. SYSREF Setup and Hold Time Requirements—SYSREF Low to High Transition Using Rising Edge Clock (Default)

Figure 126. SYSREF High to Low Transition Using Falling Edge Clock Capture (Register 0x0120, Bit 4 = 1'b1; Register 0x0120, Bit 3 = 1'b1)

Figure 127. SYSREF Ignore Example (SYSREF Ignore Count, Register 0x0121, Bits[3:0] = 3)

Figure 128. SYSREF Skew Window
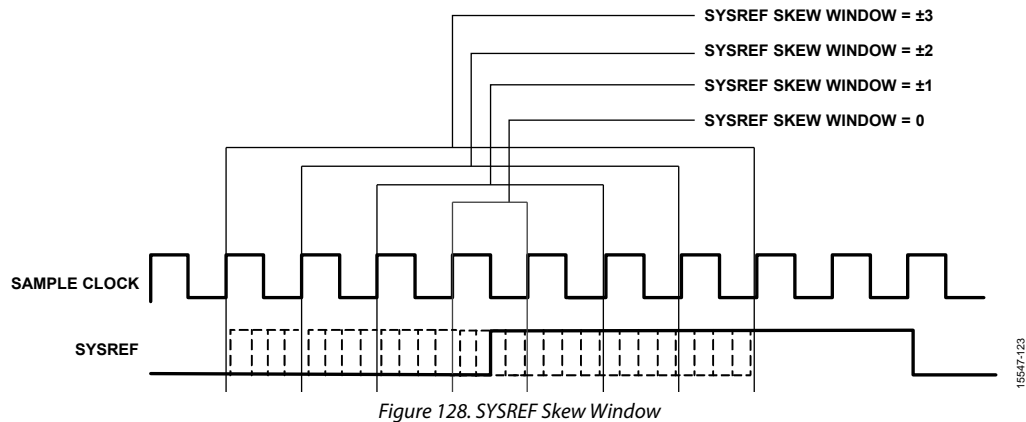

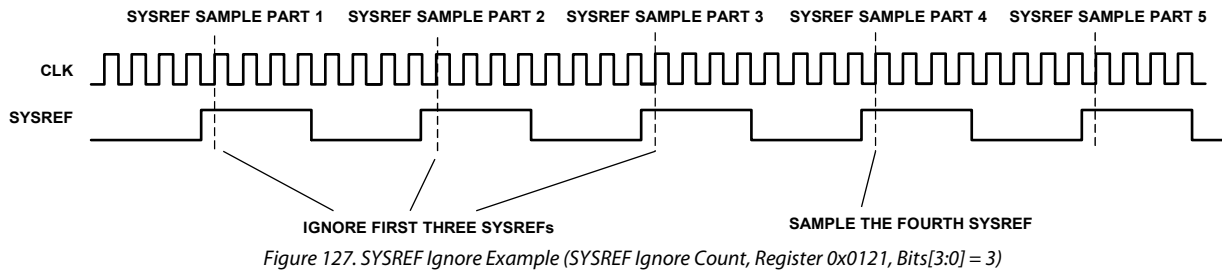

When in continuous SYSREF mode (Register 0x0120, Bits[2:1] = 1), the AD9208 monitors the placement of the SYSREF leading edge compared to the internal LMFC. If the SYSREF is captured with a clock edge other than the one that is aligned with LMFC, the AD9208 initiates a resynchronization of the link. Because input clock rates for AD9208 can be up to 4 GHz, the AD9208 provides another SYSREF related feature that makes it possible to accommodate periodic SYSREF signals where cycle accurate capture is not feasible or not required. For these scenarios, the AD9208 has a programmable SYSREF skew window that allows the internal dividers to remain undisturbed unless SYSREF occurs outside the skew window. The resolution of the SYSREF skew window is set in sample clock cycles. If the SYSREF negative skew window is 1 and the positive skew window is 1, the total skew window is ±1 sample clock cycles, meaning that, as long as

SYSREF is captured within ±1 sample clock cycle of the clock that is aligned with LMFC, the link continues to operate normally. If the SYSREF has jitter, which can cause a misalignment between SYSREF and LMFC, this feature allows the system to continue running without a resynchronization, while still allowing the device to monitor for larger errors not caused by jitter. For the AD9208, the positive and negative skew window is controlled by the SYSREF window negative register (Register 0x0122, Bits[3:2]) and SYSREF window positive register (Register 0x0122, Bits[1:0]). Figure 128 shows information on the location of the skew window settings relative to Phase 0 of the internal dividers. Negative skew is defined as occurring before the internal dividers reach Phase 0, and positive skew is defined after the internal dividers reach Phase 0.

SYSREF± SETUP/HOLD WINDOW MONITOR

To ensure a valid SYSREF signal capture, the AD9208 has a SYSREF± setup/hold window monitor. This feature allows the system designer to determine the location of the SYSREF± signals relative to the CLK± signals by reading back the amount of setup/hold margin on the interface through the memory map. Figure 129 and Figure 130 show the setup and hold status values for different phases of SYSREF±. The setup detector returns the status of the SYSREF± signal before the CLK± edge, and the hold detector returns the status of the SYSREF signal after the CLK± edge. Register 0x0128 stores the status of SYSREF± and notifies the user if the SYSREF± signal is captured by the ADC.

Table 36 shows the description of the contents of Register 0x0128 and how to interpret them.
Figure 129. SYSREF± Setup Detector
Figure 130. SYSREF± Hold Detector

Table 36. SYSREF± Setup/Hold Monitor, Register 0x0128

Register 0x0128, Bits[7:4] Hold Status	Register 0x0128, Bits[3:0] Setup Status	Description
0x0	0x0 to 0x7	Possible setup error. The smaller this number, the smaller the setup margin.
0x0 to 0x8	0x8	No setup or hold error (best hold margin).
0x8	0x9 to 0xF	No setup or hold error (best setup and hold margin).
0x8	0x0	No setup or hold error (best setup margin).
0x9 to 0xF	0x0	Possible hold error. The larger this number, the smaller the hold margin.
0x0	0x0	Possible setup or hold error.

LATENCY

END TO END TOTAL LATENCY

Total latency in the AD9208 is dependent on the chip application mode and the JESD204B configuration. For any given combination of these parameters, the latency is deterministic, however, the value of this deterministic latency must be calculated as described in the Example Latency Calculations section.

Table 34 shows the combined latency through the ADC and DSP for the different chip application modes supported by the AD9208. Table 35 shows the latency through the JESD204B block for each application mode based on the M/L ratio. For both tables, latency is typical and is in units of the encode clock. The latency through the JESD204B block does not depend on the output data type (real or complex). Therefore, data type is not included in Table 35.

To determine the total latency, select the appropriate ADC + DSP latency from Table 34 and add it to the appropriate JESD204B latency from Table 35. Example calculations are provided in the following section.

EXAMPLE LATENCY CALCULATIONS

Example Configuration 1 is as follows:

- ADC application mode = full bandwidth
- Real outputs
- L = 8, M = 2, F = 1, S = 2 (JESD204B mode)
- $20 \times (M/L) = 5$
- Latency = 31 + 44 = 75 encode clocks

Example Configuration 2 is as follows:

- ADC application mode = DCM4
- Complex outputs
- L = 4, M = 2, F = 1, S = 1 (JESD204B mode)
- $20 \times (M/L) = 10$
- Latency = 162 + 88 = 250 encode clocks

LMFC REFERENCED LATENCY

Some FPGA vendors may require the end user to know LMFC-referenced latency to make appropriate deterministic latency adjustments. If they are required, the latency values in Table 34 and Table 35 can be used for the analog in to LMFC and LMFC to data out latency values.

Table 37. Latency Through the ADC + DSP Blocks (Number of Sample Clocks)[1]

Chip Application Mode	Enabled Filters	ADC + DSP Latency
Full Bandwidth	Not applicable	31
DCM1 (Real)	HB1	90
DCM2 (Complex)	HB1	90
DCM3 (Complex)	TB1	102
DCM2 (Real)	HB2 + HB1	162
DCM4 (Complex)	HB2 + HB1	162
DCM3 (Real)	TB2 + HB1	212
DCM6 (Complex)	TB2 + HB1	212
DCM4 (Real)	HB3 +HB2 + HB1	292
DCM8 (Complex)	HB3 +HB2 + HB1	292
DCM5 (Real)	FB2 + HB1	380

DCM5	N/A	203[3]	109[3]	62[3]	43[3]	N/A	N/A
DCM6	N/A	243	130	73	39	21	14
DCM8	N/A	323	172	96	50	27	18
DCM10	N/A	N/A	213	119	62	33	22
DCM12	N/A	N/A	255	142	73	39	27
DCM15	N/A	N/A	318[4]	176[4]	90[4]	47[4]	33[4]
DCM16	N/A	N/A	339[4]	188[4]	96[4]	50[4]	35[4]
DCM20	N/A	N/A	N/A	233	119	62	43
DCM24	N/A	N/A	N/A	279	142	73	51
DCM30	N/A	N/A	N/A	348[4]	176[4]	90[4]	62[4]
DCM40	N/A	N/A	N/A	N/A	233[4]	119[4]	82[4]
DCM48	N/A	N/A	N/A	N/A	279[4]	142[4]	97[4]

[1] N/A means not applicable and indicates that the application mode is not supported at the M/L ratio listed.
[2] M/L ratio is the number of converters divided by the number of lanes for the configuration.
[3] The application mode at the M/L ratio listed is only supported in real output mode.
[4] The application mode at the M/L ratio listed is only supported in complex output mode.

TEST MODES

ADC TEST MODES

The AD9208 has various test options that aid in the system level implementation. The AD9208 has ADC test modes that are available in Register 0x550. These test modes are described in Table 39. When an output test mode is enabled, the analog section of the ADC is disconnected from the digital back-end blocks, and the test pattern is run through the output formatting block. Some of the test patterns are subject to output formatting, and some are not. The PN generators from the PN sequence tests can be reset by setting Bit 4 or Bit 5 of Register 0x0550. These tests can be performed with or without an analog signal (if present, the analog signal is ignored); however, they do require an encode clock.

If the application mode is set to select a DDC mode of operation, the test modes must be enabled for each DDC enabled. The test patterns can be enabled via Bit 2 and Bit 0 of Register 0x0327, Register 0x0347, and Register 0x0367, depending on which DDC(s) are selected. The (I) data uses the test patterns selected for Channel A, and the (Q) data uses the test patterns selected for Channel B. For DDC3 only, the (I) data uses the test patterns from Channel A, and the (Q) data does not output test patterns. Bit 0 of Register 0x0387 selects the Channel A test patterns to be used for the (I) data. For more information, see the AN-877 Application Note, *Interfacing to High Speed ADCs via SPI*.

Table 39. ADC Test Modes

Output Test Mode Bit Sequence	Pattern Name	Expression	Default/ Seed Value	Sample (N, N + 1, N + 2, …)
0000	Off (default)	Not applicable	Not applicable	Not applicable
0001	Midscale short	0000 0000 0000	Not applicable	Not applicable
0010	+Full-scale short	01 1111 1111 1111	Not applicable	Not applicable
0011	−Full-scale short	10 0000 0000 0000	Not applicable	Not applicable
0100	Checkerboard	10 1010 1010 1010	Not applicable	0x1555, 0x2AAA, 0x1555, 0x2AAA, 0x1555
0101	PN sequence long	$x^{23} + x^{18} + 1$	0x3AFF	0x3FD7, 0x0002, 0x26E0, 0x0A3D, 0x1CA6
0110	PN sequence short	$x^9 + x^5 + 1$	0x0092	0x125B, 0x3C9A, 0x2660, 0x0c65, 0x0697
0111	One-/zero-word toggle	11 1111 1111 1111	Not applicable	0x0000, 0x3FFF, 0x0000, 0x3FFF, 0x0000

1111	Ramp output	$(x)\ \%\ 2^{14}$	Not applicable	$(x)\ \%\ 2^{14}$, $(x+1)\ \%\ 2^{14}$, $(x+2)\ \%\ 2^{14}$, $(x+3)\ \%\ 2^{14}$

JESD204B BLOCK TEST MODES

In addition to the ADC pipeline test modes, the AD9208 also has flexible test modes in the JESD204B block. These test modes are listed in Register 0x0573 and Register 0x0574. These test patterns can be injected at various points along the output datapath. These test injection points are shown in Figure 107. Table 40 describes the various test modes available in the JESD204B block. For the AD9208, a transition from test modes (Register 0x0573 ≠ 0x00) to normal mode (Register 0x0573 = 0x00) requires an SPI soft reset. This is done by writing 0x81 to Register 0x0000 (self cleared).

Transport Layer Sample Test Mode

The transport layer samples are implemented in the AD9208 as defined by Section 5.1.6.3 in the JEDEC JESD204B specification.

These tests are shown in Register 0x0571, Bit 5. The test pattern is equivalent to the raw samples from the ADC.

Interface Test Modes

The interface test modes are described in Register 0x0573, Bits[3:0]. These test modes are also explained in Table 40. The interface tests can be injected at various points along the data. See Figure 107 for more information on the test injection points. Register 0x0573, Bits[5:4] show where these tests are injected.

Table 41, Table 42, and Table 43 show examples of some of the test modes when injected at the JESD204B sample input, PHY 10-bit input, and scrambler 8-bit input. UPx in the tables represent the user pattern control bits from the user register map.

Table 40. JESD204B Interface Test Modes

Output Test Mode Bit Sequence	Pattern Name	Expression	Default
0000	Off (default)	Not applicable	Not applicable
0001	Alternating checker board	0x5555, 0xAAAA, 0x5555, …	Not applicable
0010	1/0 word toggle	0x0000, 0xFFFF, 0x0000, …	Not applicable
0011	31-bit PN sequence	$x^{31} + x^{28} + 1$	0x0003AFFF
0100	23-bit PN sequence	$x^{23} + x^{18} + 1$	0x003AFF
0101	15-bit PN sequence	$x^{15} + x^{14} + 1$	0x03AF
0110	9-bit PN sequence	$x^9 + x^5 + 1$	0x092
0111	7-bit PN sequence	$x^7 + x^6 + 1$	0x07
1000	Ramp output	$(x)\ \% \ 2^{16}$	Ramp size depends on test injection point
1110	Continuous/repeat user test	Register 0x0551 to Register 0x0558	User Pattern 1 to User Pattern 4, then repeat
1111	Single user test	Register 0x0551 to Register 0x0558	User Pattern 1 to User Pattern 4, then zeros

Data Link Layer Test Modes

The data link layer test modes are implemented in the AD9208 as defined by Section 5.3.3.8.2 in the JEDEC JESD204B Specification. These tests are shown in Register 0x0574, Bits[2:0]. Test patterns inserted at this point are useful for verifying the functionality of the data link layer. When the data link layer test modes are enabled, disable SYNCINB± by writing 0xC0 to Register 0x0572.

SERIAL PORT INTERFACE

The AD9208 SPI allows the user to configure the converter for specific functions or operations through a structured register space provided inside the ADC. The SPI gives the user added flexibility and customization, depending on the application. Addresses are accessed via the serial port and can be written to or read from via the port. Memory is organized into bytes that can be further divided into fields. These fields are documented in the Memory Map section. For detailed operational information, see the Serial Control Interface Standard (Rev. 1.0).

CONFIGURATION USING THE SPI

Three pins define the SPI of the AD9208 ADC: the SCLK pin, the SDIO pin, and the CSB pin (see Table 44). The SCLK (serial clock) pin synchronizes the read and write data presented from/to the ADC. The SDIO (serial data input/output) pin is a dual-purpose pin that allows data to be sent and read from the internal ADC memory map registers. The CSB (chip select bar) pin is an active low control that enables or disables the read and write cycles.

Table 44. SPI Pins

Pin	Function
SCLK	Serial clock. The serial shift clock input that is used to synchronize serial interface, reads, and writes.
SDIO	Serial data input/output. A dual-purpose pin that typically serves as an input or an output, depending on the instruction being sent and the relative position in the timing frame.
CSB	Chip select bar. An active low control that gates the read and write cycles.

The falling edge of CSB, in conjunction with the rising edge of SCLK, determines the start of the framing. An example of the serial timing and its definitions can be found in Figure 4 and Table 5.

Other modes involving the CSB pin are available. The CSB pin can be held low indefinitely, which permanently enables the device; this is called streaming. The CSB can stall high between bytes to allow additional external timing. When CSB is tied high, SPI functions are placed in a high impedance mode. This mode turns on any SPI pin secondary functions.

All data is composed of 8-bit words. The first bit of each individual byte of serial data indicates whether a read or write command is issued, which allows the SDIO pin to change direction from an input to an output.

In addition to word length, the instruction phase determines whether the serial frame is a read or write operation, allowing the serial port to be used both to program the chip and to read the contents of the on-chip memory. If the instruction is a readback operation, performing a readback causes the SDIO pin to change direction from an input to an output at the appropriate point in the serial frame.

Data can be sent in MSB first mode or in LSB first mode. MSB first is the default on power-up and can be changed via the SPI port configuration register. For more information about this and other features, see the Serial Control Interface Standard (Rev. 1.0).

HARDWARE INTERFACE

The pins described in Table 44 comprise the physical interface between the user programming device and the serial port of the AD9208. The SCLK pin and the CSB pin function as inputs when using the SPI interface. The SDIO pin is bidirectional, functioning as an input during write phases and as an output during readback.

The SPI interface is flexible enough to be controlled by either FPGAs or microcontrollers. One method for SPI configuration is described in detail in the AN-812 Application Note, Microcontroller-Based Serial Port Interface (SPI) Boot Circuit.

Do not activate the SPI port during periods when the full dynamic performance of the converter is required. Because the SCLK signal, the CSB signal, and the SDIO signal are typically asynchronous to the ADC clock, noise from these signals can degrade converter performance. If the on-board SPI bus is used for other devices, it may be necessary to provide buffers between this bus and the AD9208 to prevent these signals from transitioning at the converter inputs during critical sampling periods.

SPI ACCESSIBLE FEATURES

Table 45 provides a brief description of the general features that are accessible via the SPI. These features are described in detail in the Serial Control Interface Standard (Rev. 1.0). The AD9208 device specific features are described in the Memory Map section.

Table 45. Features Accessible Using the SPI

Feature	Description
Mode	Allows the user to set either power-down mode or standby mode.
Clock	Allows the user to access the clock divider via the SPI.
DDC	Allows the user to set up decimation filters for different applications.
Test Input/Output	Allows the user to set test modes to have known data on output bits.
Output Mode	Allows the user to set up outputs.
SERDES Output Setup	Allows the user to vary SERDES settings such as swing and emphasis.

MEMORY MAP

READING THE MEMORY MAP REGISTER TABLE

Each row in the memory map register table has eight bit locations. The memory map is divided into the following sections:

- Analog Devices SPI registers (Register 0x0000 to Register 0x000F)
- Clock/SYSREF/chip power-down pin control registers (Register 0x003F to Register 0x0201)
- Fast detect and signal monitor control registers (Register 0x0245 to Register 0x027A)
- DDC function registers (Register 0x0300 to Register 0x03CD)
- Digital outputs and test modes registers (Register 0x0550 to Register 0x05CB)
- Programmable filter control and coefficients registers (Register 0x0DF8 to Register 0x0F7F)
- VREF/analog input control registers (Register 0x18A6 to Register 0x1A4D)

Table 43 (see the Memory Map Register Details section) documents the default hexadecimal value for each hexadecimal address shown. The column with the heading Bit 7 (MSB) is the start of the default hexadecimal value given. For example, Address 0x0561, the output sample mode register, has a hexadecimal default value of 0x01, which means that Bit 0 = 1, and the remaining bits are 0s. This setting is the default output format value, which is twos complement. For more information on this function and others, see Table 43.

Open and Reserved Locations

All address and bit locations that are not included in Table 43 are not currently supported for this device. Write unused bits of a valid address location with 0s unless the default value is set otherwise. Writing to these locations is required only when part of an address location is unassigned (for example, Address 0x0561). If the entire address location is open (for example, Address 0x0013), do not write to this address location.

Default Values

After the AD9208 is reset, critical registers are loaded with default values. The default values for the registers are given in the memory map register table, Table 43.

Logic Levels

An explanation of logic level terminology follows:

- "Bit is set" is synonymous with "bit is set to Logic 1" or "writing Logic 1 for the bit."
- "Clear a bit" is synonymous with "bit is set to Logic 0" or "writing Logic 0 for the bit."
- X denotes a don't care bit.

Channel Specific Registers

Some channel setup functions, such as the buffer control register (Register 0x1A4C), can be programmed to a different value for each channel. In these cases, channel address locations are internally duplicated for each channel. These registers and bits are designated in Table 43 as local. These local registers and bits can be accessed by setting the appropriate Channel A or Channel B bits in Register 0x0008. If both bits are set, the subsequent write affects the registers of both channels. In a read cycle, set only Channel A or Channel B to read one of the two registers. If both bits are set during an SPI read cycle, the device returns the value for Channel A. Registers and bits designated as global in Table 43 affect the entire device and the channel features for which independent settings are not allowed between channels. The settings in Register 0x0005 do not affect the global registers and bits.

SPI Soft Reset

After issuing a soft reset by programming 0x81 to Register 0x0000, the AD9208 requires 5 ms to recover. When programming the AD9208 for application setup, ensure that an adequate delay is programmed into the firmware after asserting the soft reset and before starting the device setup.

MEMORY MAP REGISTER DETAILS

All address locations that are not included in Table 46 are not currently supported for this device and must not be written.

Table 46. Memory Map Register Details

Addr.	Name	Bits	Bit Name	Settings	Description	Reset	Access
Analog Devices SPI Registers							
0x0000	SPI Configuration A	7	Soft reset mirror (self clearing)		Whenever a soft reset is issued, the user must wait 5 ms before writing to any other register. This provides sufficient time for the boot loader to complete.	0x0	R/WC
				0	Do nothing.		
				1	Reset the SPI and registers (self clearing).		
		6	LSB first mirror			0x0	R/W
				1	Least significant bit (LSB) shifted first for all SPI operations.		
				0	Most significant bit (MSB) shifted first for all SPI operations.		
		5	Address ascension mirror			0x0	R/W
				0	Multibyte SPI operations cause addresses to autodecrement.		
				1	Multibyte SPI operations cause addresses to autoincrement.

APPLICATIONS INFORMATION

POWER SUPPLY RECOMMENDATIONS

The power supplies needed to power the AD9208 are shown in Table 47. A power-on sequence is not required to operate the AD9208. The power supply domains can be powered up in any order.

Table 47. Typical Power Supplies for the AD9208

Domain	Voltage (V)	Tolerance (%)
AVDD1	0.975	±2.5
AVDD1_SR	0.975	±2.5
DVDD	0.975	±2.5
DRVDD1	0.975	±2.5
AVDD2	1.9	±2.5
DRVDD2	1.9	±2.5
SPIVDD	1.9	±2.5
AVDD3	2.5	±2.5

For applications requiring an optimal high power efficiency and low noise performance, it is recommended that the ADP5054 quad switching regulator be used to convert an input voltage in the 6.0 V to 15 V range to intermediate rails (1.3 V, 2.4 V, and 3.0 V). These intermediate rails are then postregulated by very low noise, low dropout (LDO) regulators (ADP1763, ADP7159, and ADP151). Figure 131 shows the recommended power supply scheme for the AD9208.

Figure 131. High Efficiency, Low Noise Power Solution for the AD9208

It is not necessary to split all of these power domains in all cases. The recommended solution shown in Figure 131 provides the lowest noise, highest efficiency power delivery system for the AD9208. If only one 0.975 V supply is available, route to AVDD1 first and then tap it off and isolate it with a ferrite bead or a filter choke, preceded by decoupling capacitors for AVDD1_SR, DVDD, and DRVDD1, in that order. Figure 132 shows the simplified schematic. The dc resistance (DCR) of the ferrite bead must be taken into consideration when choosing the appropriate ferrite bead. Otherwise, excessive loss across the ferrite bead can lead to a malfunctioning ADC. Adjustable LDOs can be employed to output a higher voltage to account for the drop across the ferrite bead.

Alternatively, the LDOs can be bypassed altogether and the AD9208 can be driven directly from the dc-to-dc converter. Note that this approach has risks in that there may be more power supply noise injected into the power supply domains of the ADC. To minimize noise, follow the layout guidelines of the dc-to-dc converter.

Figure 132. Simplified Power Solution for the AD9208

The user can employ several different decoupling capacitors to cover both high and low frequencies. These capacitors must be located close to the point of entry at the PCB level and close to the devices, with minimal trace lengths.

LAYOUT GUIDELINES

The ADC evaluation board can be used as a guide to follow good layout practices. The evaluation board layout is set up in such a way as to

- Minimize coupling between the analog inputs (Channel A to Channel B and Channel B to Channel A).
- Minimize clock coupling to the analog inputs.
- Provide enough power and ground planes for the various supply domains while reducing cross coupling.
- Provide adequate thermal relief to the ADC.

Figure 133 shows the overall layout scheme used for the AD9208 evaluation board.

AVDD1_SR (PIN E7) AND AGND (PIN E6 AND PIN E8)

AVDD1_SR (Pin E7) and AGND (Pin E6 and Pin E8) can be used to provide a separate power supply node to the SYSREF± circuits of the AD9208. If running in Subclass 1, the AD9208 can support periodic one-shot or gapped signals. To minimize the coupling of this supply into the AVDD1 supply node, adequate supply bypassing is needed.

Figure 133. Recommended PCB Layout for the AD9208

OUTLINE DIMENSIONS

COMPLIANT TO JEDEC STANDARDS MO-275-GGAB-1.

OCEAN CHIPS
Океан Электроники
Поставка электронных компонентов

Компания «Океан Электроники» предлагает заключение долгосрочных отношений при поставках импортных электронных компонентов на взаимовыгодных условиях!

Наши преимущества:

- Поставка оригинальных импортных электронных компонентов напрямую с производств Америки, Европы и Азии, а так же с крупнейших складов мира;
- Широкая линейка поставок активных и пассивных импортных электронных компонентов (более 30 млн. наименований);
- Поставка сложных, дефицитных, либо снятых с производства позиций;
- Оперативные сроки поставки под заказ (от 5 рабочих дней);
- Экспресс доставка в любую точку России;
- Помощь Конструкторского Отдела и консультации квалифицированных инженеров;
- Техническая поддержка проекта, помощь в подборе аналогов, поставка прототипов;
- Поставка электронных компонентов под контролем ВП;
- Система менеджмента качества сертифицирована по Международному стандарту ISO 9001;
- При необходимости вся продукция военного и аэрокосмического назначения проходит испытания и сертификацию в лаборатории (по согласованию с заказчиком);
- Поставка специализированных компонентов военного и аэрокосмического уровня качества (Xilinx, Altera, Analog Devices, Intersil, Interpoint, Microsemi, Actel, Aeroflex, Peregrine, VPT, Syfer, Eurofarad, Texas Instruments, MS Kennedy, Miteq, Cobham, E2V, MA-COM, Hittite, Mini-Circuits, General Dynamics и др.);

Компания «Океан Электроники» является официальным дистрибьютором и эксклюзивным представителем в России одного из крупнейших производителей разъемов военного и аэрокосмического назначения «JONHON», а так же официальным дистрибьютором и эксклюзивным представителем в России производителя высокотехнологичных и надежных решений для передачи СВЧ сигналов «FORSTAR».

«JONHON» (основан в 1970 г.)

Разъемы специального, военного и аэрокосмического назначения:

(Применяются в военной, авиационной, аэрокосмической, морской, железнодорожной, горно- и нефтедобывающей отраслях промышленности)

«FORSTAR» (основан в 1998 г.)

ВЧ соединители, коаксиальные кабели, кабельные сборки и микроволновые компоненты:

(Применяются в телекоммуникациях гражданского и специального назначения, в средствах связи, РЛС, а так же военной, авиационной и аэрокосмической отраслях промышленности).
