## Description

Atmel's AT16373 devices provide maximum speed in temporary data storage. They can be operated as either two separate 8 bit latches or as a single 16-bit latch by use of the output enable and the latch enable. The AT16373 has very low ground bounce and excellent input noise rejection, giving the user stable signals in a high speed environment. These devices can drive very large loads while operating in a high speed transparent mode.

Note: 1. This 8-bit latch function is repeated a second time on each device.

## Test Circuits<sup>(1,2)</sup>

- Note: 1. Pulse Generator: Rate  $\leq 1.0$  MHz,  $t_F \leq 2.5$  ns,  $t_R \leq 2.5$  ns.  
 2. AC tests are done with a single bit switching, and timings need to be derated when multiple outputs are switching in the same direction simultaneously. This derating should not exceed 0.5 ns for 16 inputs switching simultaneously.

## Switch Position

Test	Switch
Open Drain Disable Low Enable Low	Closed
All Other Tests	Open

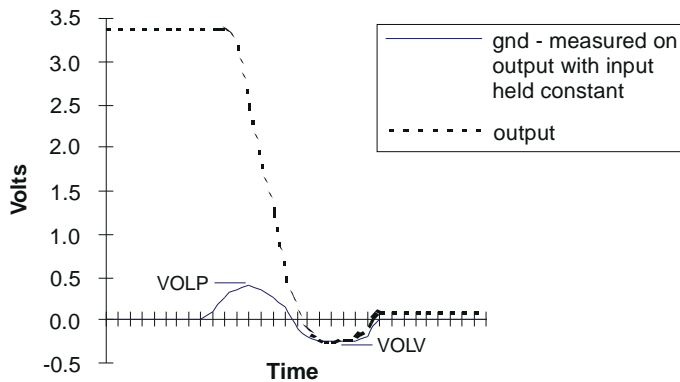

### Definitions:

$C_L$  = Load capacitance; Includes jig and probe capacitance.  
 $R_T$  = Termination resistance; Should be equal to  $Z_{OUT}$  of the Pulse Generator.

## IOL Pull Down Current

## Ground Bounce for High to Low Transitions<sup>(1)</sup>

## Supply Bounce for Low to High Transitions<sup>(2)</sup>

## Typical Values

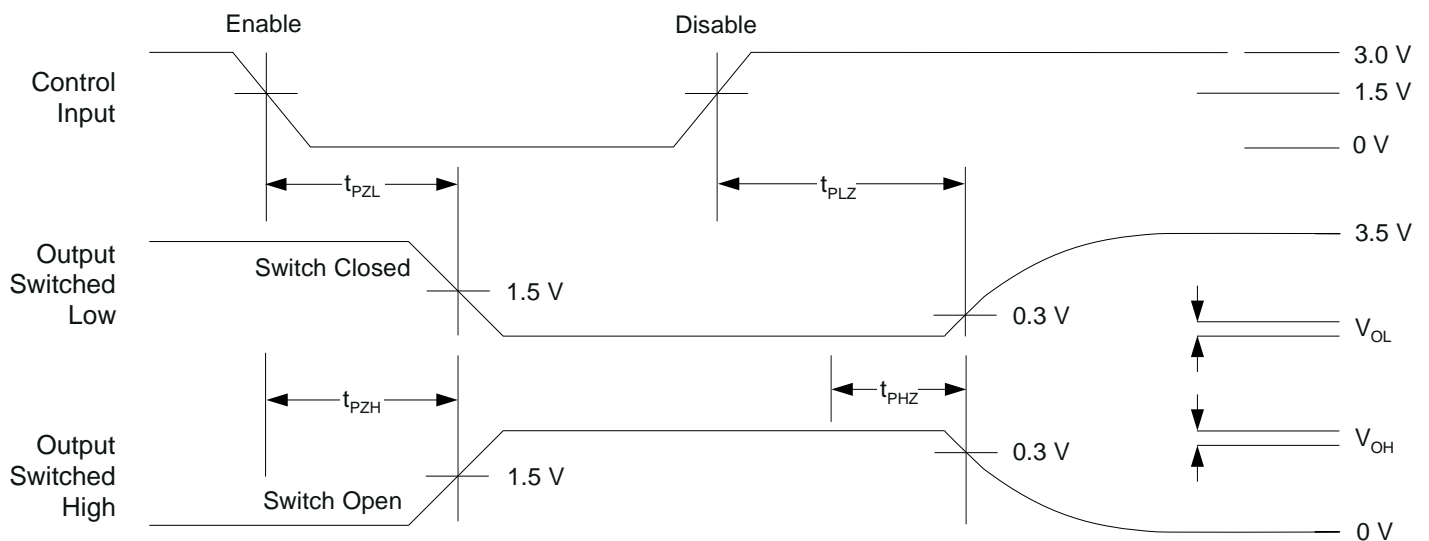

Parameter	Value	Units
VOLP	0.4	V
VOLV	-0.26	V
VOHV	$V_{CC} - 0.13$	V
VOHP	$V_{CC} + 0.6$	V

- Note: 1. When multiple outputs are switched at the same time, rapidly changing current on the ground and VCC paths causes a voltage to develop across the parasitic inductance of the wire bond and package pins. This occurrence is called simultaneous switching noise. Atmel's AT16373 products have minimized this phenomenon as shown on the graph. Output data is for 15 outputs switching simultaneously at a frequency of 1 MHz. The ground data is measured on the one remaining output, which is set to logic low and will reflect any device ground movement.
2. As on the graph for Ground Bounce, a similar condition occurs for low to high transitions. Output data is for 15 outputs switching simultaneously at a frequency of 1 MHz.  $V_{CC}$  droop is measured on the one remaining output pin, which is set to a logic high. This output will reflect any movement on the device  $V_{CC}$ .

## Enable and Disable Waveforms<sup>(1)</sup>

- Note: 1. Enable and disable waveforms are the same for both  $\overline{xOE}$  and  $xLE$  inputs.
