

FEATURES

- Four 4.5 V rms (typical) differential inputs
- On-chip phase-locked loop (PLL) for master clock
- Low electromagnetic interference (EMI) design
- 109 dB (typical) analog-to-digital converter (ADC) dynamic range
- Total harmonic distortion + noise (THD + N): -95 dB (typical)
- Selectable digital high-pass filter
- 24-bit stereo ADC with 8 kHz to 192 kHz sample rates
- Digital volume control with autoramp function
- I²C/SPI controllable for flexibility
- Software-controllable clickless mute
- Software power-down
- Right justified, left justified, I²S, and TDM modes
- Master and slave operation modes
- 40-lead LFCSP package
- Qualified for automotive applications

APPLICATIONS

- Automotive audio systems
- Active noise cancellation systems

GENERAL DESCRIPTION

The ADAU1979 incorporates four high performance, analog-to-digital converters (ADCs) with 4.5 V rms capable ac-coupled inputs. The ADCs use a multibit sigma-delta (Σ - Δ) architecture with continuous time front end for low EMI. An I²C/serial peripheral interface (SPI) control port is included that allows a microcontroller to adjust volume and many other parameters. The ADAU1979 uses only a single 3.3 V supply. The device internally generates the required digital DVDD supply. The low power architecture reduces the power consumption. The on-chip PLL can derive the master clock from an external clock input or frame clock (sample rate clock). When fed with the frame clock, it eliminates the need for a separate high frequency master clock in the system. The ADAU1979 is available in a 40-lead LFCSP package.

Note that throughout this data sheet, multifunction pins, such as SCL/CCLK, are referred to either by the entire pin name or by a single function of the pin, for example, CCLK, when only that function is relevant.

REVISION HISTORY

11/13—Revision 0: Initial Version

SPECIFICATIONS

Performance of all channels is identical, exclusive of the interchannel gain mismatch and interchannel phase deviation specifications. AVDDx/IOVDD = 3.3 V; DVDD (internally generated) = 1.8 V; T_A = -40°C to +105°C, unless otherwise noted. Master clock = 12.288 MHz (48 kHz f_s, 256 × f_s mode); input sample rate = 48 kHz; measurement bandwidth = 20 Hz to 20 kHz; word width = 24 bits; load capacitance (digital output) = 20 pF; load current (digital output) = ±1 mA; digital input voltage high = 2.0 V; and digital input voltage low = 0.8 V.

ANALOG PERFORMANCE SPECIFICATIONS

ABSOLUTE MAXIMUM RATINGS

Table 6.

Parameter	Rating
Analog (AVDDx) Supply	-0.3 V to +3.6 V
Digital Supply	
DVDD	-0.3 V to +1.98 V
IOVDD	-0.3 V to +3.63 V
Input Current (Except Supply Pins)	±20 mA
Analog Input Voltage (Signal Pins)	-0.3 V to +3.6 V
Digital Input Voltage (Signal Pins)	-0.3 V to +3.6 V
Operating Temperature Range (Ambient)	-40°C to +105°C
Junction Temperature Range	-40°C to +125°C
Storage Temperature Range	-65°C to +150°C

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

THERMAL RESISTANCE

θ_{JA} represents junction-to-ambient thermal resistance, and θ_{JC} represents the junction-to-case thermal resistance. All characteristics are for a standard JEDEC board per JESD51.

Table 7. Thermal Resistance

Package Type	θ_{JA}	θ_{JC}	Unit
40-Lead LFCSP	32.8	1.93	°C/W

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

- NOTES**
1. NC = NO CONNECT. DO NOT CONNECT TO THESE PINS. LEAVE THE NC PINS OPEN.
 2. THE EXPOSED PAD MUST BE CONNECTED TO THE GROUND PLANE ON THE PRINTED CIRCUIT BOARD (PCB).

THEORY OF OPERATION

OVERVIEW

The ADAU1979 incorporates four high performance ADCs and a phase-locked loop (PLL) circuit for generating the necessary on-chip clock signals.

POWER SUPPLY AND VOLTAGE REFERENCE

The ADAU1979 requires a single 3.3 V power supply. Decouple all AVDDx pins to the nearest AGNDx pin with 100 nF ceramic chip capacitors placed as near the AVDDx pins as possible to minimize noise pickup. A bulk aluminum electrolytic capacitor of at least 10 μF must be provided on the same PCB as the ADC. It is important that the analog supply be as clean as possible for best performance.

The supply voltage for the digital core (DVDD) is generated using an internal low dropout regulator. The typical DVDD output is 1.8 V and must be decoupled using a 100 nF ceramic capacitor and a 10 μF capacitor. Place the 100 nF ceramic capacitor as near the DVDD pin as possible.

The voltage reference for the analog blocks is generated internally and output at the VREF pin (Pin 2). The typical voltage at the VREF pin is 1.5 V with an AVDDx of 3.3 V.

All digital inputs are compatible with TTL and CMOS levels. All outputs are driven from the IOVDD supply. The IOVDD can be in the 1.8 V to 3.3 V range. The IOVDD pin must be decoupled with a 100 nF capacitor placed as near the IOVDD pin as possible.

The ADC internal voltage reference is output from the VREF pin and must be decoupled using a 100 nF ceramic capacitor in parallel with a 10 μF capacitor. The VREF pin has limited current capability. The voltage reference is used as a reference to the ADC; therefore, it is recommended not to draw current from this pin for external circuits. When using this reference, use a noninverting amplifier buffer to provide a reference to other circuits in the application.

In reset mode, the VREF pin is disabled to save power and is enabled only when the $\overline{\text{PD/RST}}$ pin is pulled high.

POWER-ON RESET SEQUENCE

The ADAU1979 requires that a single 3.3 V power supply be provided externally at the AVDDx pin. The device internally generates DVDD (1.8 V), which is used for the digital core of the ADC. The DVDD supply output pin (Pin 10) is provided to connect the decoupling capacitors to DGND. The typical recommended values for the decoupling capacitors are 100 nF in parallel with 10 μF . During a reset, the DVDD regulator is disabled to reduce power consumption. After the $\overline{\text{PD/RST}}$ pin (Pin 6) is pulled high, the device enables the DVDD regulator. However, the internal ADC and digital core reset are controlled by the internal power-on reset (POR) signal circuit, which monitors the DVDD level. Therefore, the device does not exit a reset until DVDD reaches 1.2 V and the $\overline{\text{POR}}$ signal is released.

The DVDD settling time depends on the charge-up time for the external capacitors and on the AVDDx ramp-up time.

The internal POR circuit is provided with hysteresis to ensure that a reset of the device is not initiated by an instantaneous glitch on DVDD. The typical trip points are 1.2 V with $\overline{\text{PD/RST}}$ high and 0.6 V ($\pm 20\%$) with $\overline{\text{PD/RST}}$ low. This ensures that the core is not reset until the DVDD level falls below the 0.6 V trip point.

As soon as the $\overline{\text{PD/RST}}$ pin is pulled high, the internal regulator starts charging up C_{EXT} on the DVDD pin. The DVDD charge-up time is based on the output resistance of the regulator and the external decoupling capacitor. The time constant can be calculated as

$$t_c = R_{\text{OUT}} \times C_{\text{EXT}}$$

where $R_{\text{OUT}} = 20 \Omega$ typical.

For example, if C_{EXT} is 10 μF , t_c is 200 μs and is the time that it takes to reach the DVDD voltage, within 63.6%.

The power-on reset circuit releases an internal reset of the core when DVDD reaches 1.2 V (see Figure 13). Therefore, it is recommended to wait for at least the t_c period to elapse before sending I²C or SPI control signals.

Figure 13. Power-On Reset Timing

When applying a hardware reset to the device by pulling the $\overline{\text{PD/RST}}$ pin (Pin 6) low and then high, there are certain time restrictions. During the $\overline{\text{PD/RST}}$ low pulse period, the DVDD starts discharging. The discharge time constant is determined by the internal resistance of the regulator and C_{EXT} . Use the following equation to estimate the time required for DVDD to fall from 1.8 V to 0.48 V (0.6 V – 20%):

$$t_D = 1.32 \times R_{\text{INT}} \times C_{\text{EXT}}$$

where $R_{\text{INT}} = 64 \text{ k}\Omega$ typical. (R_{INT} can vary due to process by $\pm 20\%$.)

For example, if C_{EXT} is 10 μF , t_D is 0.845 sec.

Depending on C_{EXT} , t_D may vary and, in turn, affect the minimum hold period for the $\overline{\text{PD/RST}}$ pulse. The $\overline{\text{PD/RST}}$ pulse must be held low for the entire t_D time period to initialize the core properly.

Reduce the required $\overline{PD/RST}$ low pulse period by adding a resistor across C_{EXT} . Calculate the new t_D value as

$$t_D = 1.32 \times R_{EQ} \times C_{EXT}$$

where $R_{EQ} = 64 \text{ k}\Omega \parallel R_{EXT}$.

The resistor ensures that DVDD not only discharges quickly during a reset or an AVDDx power loss but also resets the internal blocks correctly. Note that some power loss in this resistor is to be expected because the resistor constantly draws current from DVDD. The typical value for C_{EXT} is 10 μF and 3 $\text{k}\Omega$ for R_{EXT} . This results in a time constant of

$$t_D = 1.32 \times R_{EQ} \times C_{EXT} = 37.8 \text{ ms}$$

where $R_{EQ} = 2.866 \text{ k}\Omega$ ($64 \text{ k}\Omega \parallel 3 \text{ k}\Omega$).

Using this equation at a set C_{EXT} value, the R_{EXT} can be calculated for a desired $\overline{PD/RST}$ pulse period.

There is also a software reset bit (S_{RST} , Bit 7 of Register 0x00) available that can be used to reset the part, but note that during an AVDDx power loss, the software reset may not ensure proper initialization because DVDD may not be stable.

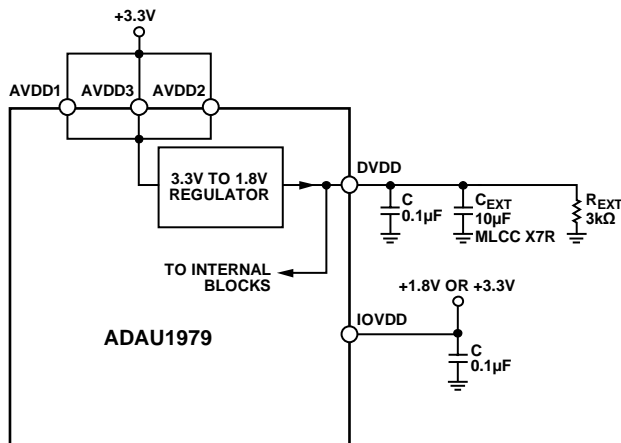

Figure 14. DVDD Regulator Output Connections

PLL AND CLOCK

The ADAU1979 has a built-in analog PLL to provide a jitter-free master clock to the internal ADC. The PLL must be programmed for the appropriate input clock frequency. The PLL_CONTROL Register 0x01 sets the PLL.

The CLK_S bit (Bit 4) of Register 0x01 sets the clock source for the PLL. The clock source can be either the MCLKIN pin or the LRCLK pin (slave mode). In LRCLK mode, the PLL supports sample rates between 32 kHz and 192 kHz.

In MCLK input mode, the MCS bits (Bits[2:0] of Register 0x01) must be set to the desired input clock frequency for the MCLKIN pin. Table 9 shows the master clock input frequency required for the most common sample rates and the MCS bit settings.

The PLL_LOCK bit (Bit 7) of Register 0x01 indicates the lock status of the PLL. It is recommended that the PLL lock status be read after initial power-up to ensure that the PLL outputs the correct frequency before unmuting the audio outputs.

Table 9. Required Master Clock Input Frequency for Common Sample Rates

MCS (Bits[2:0])	f _s (kHz)	Frequency Multiplication Ratio	MCLKIN Frequency (MHz)
000	32	128 × f _s	4.096
001	32	256 × f _s	8.192
010	32	384 × f _s	12.288
011	32	512 × f _s	16.384
100	32	768 × f _s	24.576
000	44.1	128 × f _s	5.6448
001	44.1	256 × f _s	11.2896
010	44.1	384 × f _s	16.9344
011	44.1	512 × f _s	22.5792
100	44.1	768 × f _s	33.8688
000	48	128 × f _s	6.144
001	48	256 × f _s	12.288
010	48	384 × f _s	18.432
011	48	512 × f _s	24.576
100	48	768 × f _s	36.864
000	96	64 × f _s	6.144
001	96	128 × f _s	12.288
010	96	192 × f _s	18.432
011	96	256 × f _s	24.576
100	96	384 × f _s	36.864
000	192	32 × f _s	6.144
001	192	64 × f _s	12.288
010	192	96 × f _s	18.432
011	192	128 × f _s	24.576
100	192	192 × f _s	36.864

The PLL can accept the audio frame clock (sample rate clock) as the input, but the serial port must be configured as a slave, and the frame clock must be fed to the device from the master. It is strongly recommended that the PLL be disabled, reprogrammed with the new setting, and then reenabled. A lock bit is provided that is polled via I²C to check whether the PLL has acquired lock.

The PLL requires an external filter, which is connected at the PLL_FILT pin (Pin 3). The recommended PLL filter circuit for MCLK or LRCLK mode is shown in Figure 15. Using NPO capacitors is recommended for temperature stability. Place the filter components near the device for best performance.

Figure 15. PLL Filter

ANALOG INPUTS

The ADAU1979 has four differential analog inputs. The ADCs can accommodate both dc- and ac-coupled input signals.

The block diagram shown in Figure 16 represents the typical input circuit.

In most audio applications, the dc content of the signal is removed by using a coupling capacitor. However, the ADAU1979 consists of a unique input structure that allows ac coupling of the input signals. The typical input resistance is approximately 32 kΩ from each input to AGNDx.

The high-pass filter has a 1.4 Hz, 6 dB per octave cutoff at a 48 kHz sample rate. The cutoff frequency scales directly with the sample frequency. However, care is required in dc-coupled applications to ensure that the common-mode dc voltage does not exceed the specified limit. The input required for the full-scale ADC output (0 dBFS) is typically 4.5 V rms differential.

$V_{ID} = V$ INPUT DIFFERENTIAL
 V_{CM} AT AINxP/AINxN = 1.5V

Figure 16. Analog Input Block

Line Inputs

This section describes some of the possible methods to connect the line level inputs of the ADAU1979.

Line Input Balanced or Differential Input DC-Coupled Case

For an input signal of 4.5 V rms differential with approximately 1.5 V common-mode dc, the signal at each input pin has a 2.25 V rms or 6.36 V p-p signal swing. At a common-mode dc of 1.5 V, the signal can swing between $(1.5 + 3.18) = 4.68$ V and $(1.5 - 3.18) = -1.68$ V at each input. Therefore, this is approximately 12.72 V p-p differential across AINx and AINx and measures near 0 dBFS (ac only with a dc high-pass filter) at the ADC output (see Figure 17).

Line Input Balanced or Differential Input AC-Coupled Case

For connecting the ADAU1979 to a head unit amplifier output, ac coupling is recommended. In this case, the AINx/AINx pins are at a common-mode level of 1.5 V. Use the attenuator to reduce the input level if it is more than 4.5 V rms.

Use the following equation to identify the C1 and C2 values for the required low frequency cutoff:

$$C1 \text{ or } C2 = 1/(2 \times \pi \times f_c \times \text{Input Resistance})$$

where the *Input Resistance* of the ADAU1979 is 32.17 kΩ typical.

Refer to Figure 18 for information about connecting the line level inputs to the ADAU1979.

Line Input Unbalanced or Single-Ended, Pseudo Differential AC-Coupled Case

For a single-ended application, reduce the signal swing by half because only one input is used for the signal and the other is connected to 0 V. Doing this reduces the input signal capability to 2.25 V rms in the single-ended application and measures approximately -6.16 dBFS (ac only with a dc high-pass filter) at the ADC output.

See Figure 19 for additional information. The value of C1/C2 is similar to the balanced ac-coupled case previously mentioned in the Line Input Balanced or Differential Input AC-Coupled Case section.

Figure 19. Connecting the Line Level Inputs—Pseudo Differential AC-Coupled Case

ADC

The ADAU1979 contains four Σ - Δ ADC channels configured as two stereo pairs with configurable differential/single-ended inputs. The ADC can operate at a nominal sample rate of 32 kHz up to 192 kHz. The ADCs include on-board digital antialiasing filters with 79 dB stop-band attenuation and linear phase response. Digital outputs are supplied through two serial data output pins (one for each stereo pair) and a common frame clock (LRCLK) and bit clock (BCLK). Alternatively, one of the TDM modes can be used to support up to 16 channels on a single TDM data line.

With smaller amplitude input signals, a 10-bit programmable digital gain compensation for an individual channel is provided to scale up the output word to full scale. Take care to avoid overcompensation (large gain compensation), which leads to clipping and THD degradation in the ADC.

The ADCs also have a dc offset calibration algorithm to null the systematic dc offset of the ADC. This feature is useful for dc measurement applications.

ADC SUMMING MODES

The four ADCs can be grouped into either a single stereo ADC or a single mono ADC to increase the SNR for the application. Two options are available: one option for summing two channels of the ADC and another option for summing all four channels of the ADC. Summing is performed in the digital block.

2-Channel Summing Mode

When the SUM_MODE bits (Bits[7:6] of Register 0x0E) are set to 01, the Channel 1 and Channel 2 ADC data are combined and output from the SDATAOUT1 pin. Similarly, the Channel 3 and Channel 4 ADC data are combined and output from the SDATAOUT2 pin. As a result, the SNR improves by 3 dB. For this mode, both Channel 1 and Channel 2 must be connected to the same input signal source. Similarly, Channel 3 and Channel 4 must be connected to the same input signal source.

Figure 20. 2-Channel Summing Mode Connection Diagram

1-Channel Summing Mode

When the SUM_MODE Bits (Bits[7:6] of Register 0x0E) are set to 10, the Channel 1 through Channel 4 ADC data are combined and output from the SDATAOUT1 pin. As a result, the SNR improves by 6 dB. For this mode, all four channels must be connected to the same input signal source.

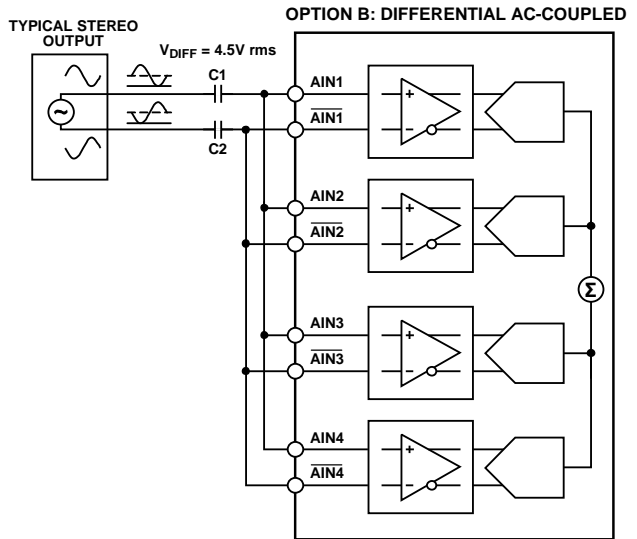

Figure 21. 1-Channel Summing Mode Connection Diagram

SERIAL AUDIO DATA OUTPUT PORTS, DATA FORMAT

The serial audio port comprises four pins: BCLK, LRCLK, SDATAOUT1, and SDATAOUT2. The ADAU1979 ADC outputs are available on the SDATAOUT1 and SDATAOUT2 pins in serial format. The BCLK and LRCLK pins serve as the bit clock and frame clock, respectively. The port can be operated as a master or slave and can be set either in stereo mode (2-channel mode) or in TDM multichannel mode. The supported popular audio formats are I²S, left justified (LJ), and right justified (RJ).

Stereo Mode

In 2-channel or stereo mode, the SDATAOUT1 outputs ADC data for Channel 1 and Channel 2, and the SDATAOUT2 outputs ADC data for Channel 3 and Channel 4. Figure 22 through Figure 24 show the supported audio formats.

TDM Mode

Register 0x05 through Register 0x08 provide programmability for the TDM mode. The TDM slot width, data width, and channel assignment, as well as the pin used to output the data, are programmable.

By default, serial data is output on the SDATAOUT1 pin; however, the SDATA_SEL bit (Bit 7 of Register 0x06) can be used to change the setting so that serial data is output from the SDATAOUT2 pin.

The TDM mode supports two, four, eight, or 16 channels. The ADAU1979 outputs four channels of data in the assigned slots

(Figure 27 shows the TDM mode slot assignments). During the unused slots, the output pin becomes high-Z so that the same data line can be shared with other devices on the TDM bus.

The TDM port can be operated as either a master or a slave. In master mode, the BCLK and LRCLK pins are output from the ADAU1979, whereas in slave mode, the BCLK and LRCLK pins are set to receive the clock from the master in the system.

Both the nonpulse and pulse modes are supported. In nonpulse mode, the LRCLK signal is typically 50% of the duty cycle, whereas in pulse mode, the LRCLK signal must be at least one BCLK wide (see Figure 25 and Figure 26).

11408-027

11408-028

Figure 27. TDM Mode Slot Assignment

11408-029

Table 10. Bit Clock Frequency TDM Mode

Mode	BCLK Frequency		
	16 Bit Clocks Per Slot	24 Bit Clocks Per Slot	32 Bit Clocks Per Slot
TDM2	$32 \times f_s$	$48 \times f_s$	$64 \times f_s$
TDM4	$64 \times f_s$	$96 \times f_s$	$128 \times f_s$
TDM8	$128 \times f_s$	$192 \times f_s$	$256 \times f_s$
TDM16	$256 \times f_s$	$384 \times f_s$	$512 \times f_s$

The bit clock frequency depends on the sample rate, the slot width, and the number of bit clocks per slot. Use Table 10 to calculate the BCLK frequency.

The sample rate (f_s) can range from 8 kHz up to 192 kHz. However, in master mode, the maximum bit clock frequency (BCLK) is 24.576 MHz. For example, for a sample rate of 192 kHz, $128 \times f_s$ is the maximum possible BCLK frequency. Therefore, only 128-bit clock cycles are available per TDM

frame. There are two options in this case: either operate with a 32-bit data width in TDM4 or operate with a 16-bit data width in TDM8. In slave mode, this limitation does not exist because the bit clock and frame clock are fed to the ADAU1979. Various combinations of BCLK frequencies and modes are available, but take care to choose the combination that is most suitable for the application.

Connection Options

Figure 28 through Figure 32 show the available options for connecting the serial audio port in I²S or TDM mode. In TDM mode, it is recommended to include a pull-down resistor on the data signal to prevent the line from floating when the SDATAOUTx pin of the ADAU1979 becomes high-Z during an inactive period. Select a resistor value such that no more than 2 mA is drawn from the SDATAOUTx pin. Although the resistor value is typically in the 10 kΩ to 47 kΩ range, the appropriate resistor value depends on the devices on the data bus.

CONTROL PORTS

The ADAU1979 control port allows two modes of operation, either 2-wire I²C mode or 4-wire SPI mode, for setting the internal registers of the device. Both the I²C and SPI modes allow read and write capability of the registers. All the registers are eight bits wide. The registers start at Address 0x00 and end at Address 0x1A.

The control port in both I²C and SPI modes is slave only and, therefore, requires the master in the system to operate. The registers can be accessed with or without the master clock to the device. However, to operate the PLL, serial audio ports, and boost converter, the master clock is necessary.

By default, the ADAU1979 operates in I²C mode, but the device can be put into SPI mode by pulling the $\overline{\text{CLATCH}}$ pin low three times.

The control port pins are multifunctional, depending on the mode in which the device is operating. Table 12 describes the control port pin functions in both modes.

I²C MODE

The ADAU1979 supports a 2-wire serial (I²C-compatible) bus protocol. Two pins, serial data (SDA) and serial clock (SCL), are used to communicate with the system I²C master controller. In I²C mode, the ADAU1979 is always a slave on the bus, meaning that it cannot initiate a data transfer. Each slave device on the I²C bus is recognized by a unique device address. The device address and R/W byte for the ADAU1979 are shown in Table 11. The address resides in the first seven bits of the I²C write. Bit 7 and Bit 6 of the I²C address for the ADAU1979 are set by the levels on the ADDR1 and ADDR0 pins. The LSB of the first I²C byte (the R/W bit) from the master identifies whether it is a read or write operation. Logic Level 1 in the LSB (Bit 0) corresponds to a read operation, and Logic Level 0 corresponds to a write operation.

Table 11. I²C First Byte Format

Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
ADDR1	ADDR0	1	0	0	0	1	R/W

The first seven bits of the I²C chip address for the ADAU1979 are xx10001. Set Bit 7 and Bit 6 of the address byte using the

ADDR1 and ADDR0 pins, which set the chip address to the desired value.

The 7-bit I²C device address can be set to one of four of the following possible options using the ADDR1 and ADDR0 pins:

- I²C Device Address 0010001 (0x11)
- I²C Device Address 0110001 (0x31)
- I²C Device Address 1010001 (0x51)
- I²C Device Address 1110001 (0x71)

In I²C mode, both the SDA and SCL pins require that an appropriate pull-up resistor be connected to IOVDD. Ensure that the voltage on these signal lines does not exceed the voltage on the IOVDD pin. Figure 44 shows a typical connection diagram for the I²C mode.

Calculate the value of the pull-up resistor for the SDA or SCL pin as follows.

$$\text{Minimum } R_{\text{PULL UP}} = (\text{IOVDD} - V_{\text{IL}}) / I_{\text{SINK}}$$

where:

IOVDD is the I/O supply voltage, typically ranging from 1.8 V up to 3.3 V.

V_{IL} is the maximum voltage at Logic Level 0 (that is, 0.4 V, as per the I²C specifications).

I_{SINK} is the current sink capability of the I/O pin.

The SDA pin can sink 2 mA of current; therefore, the minimum value of R_{PULL UP} for an IOVDD of 3.3 V is 1.5 kΩ.

Depending on the capacitance of the printed circuit board, the speed of the bus can be restricted to meet the rise time and fall time specifications.

For fast mode with a bit rate of around 1 Mbps, the rise time must be less than 550 ns. Use the following equation to determine whether the rise time specification can be met:

$$t = 0.8473 \times R_{\text{PULL UP}} \times C_{\text{BOARD}}$$

where C_{BOARD} must be less than 236 pF to meet the 300 ns rise time requirement.

For the SCL pin, the calculations depend on the current sink capability of the I²C master used in the system.

Table 12. Control Port Pin Functions

Pin No.	Mnemonic	I ² C Mode		SPI Mode	
		Pin Function	Pin Type	Pin Function	Pin Type
17	SDA/COUT	SDA data	I/O	COUT data	O

20	ADDR1/CIN	I ² C Device Address Bit 1	I	CIN data	I

Addressing

Initially, each device on the I²C bus is in an idle state and monitors the SDA and SCL lines for a start condition and the proper address. The I²C master initiates a data transfer by establishing a start condition, defined by a high-to-low transition on SDA while SCL remains high. This indicates that an address/data stream follows. All devices on the bus respond to the start condition and acquire the next eight bits from the master (the 7-bit address plus the R/W bit) MSB first. The master sends the 7-bit device address with the R/W bit to all the slaves on the bus. The device with the matching address responds by pulling the data line (SDA) low during the ninth clock pulse. This ninth bit is known as an acknowledge bit. All other devices withdraw from the bus at this point and return to the idle condition.

The R/W bit determines the direction of the data. A Logic 0 on the LSB of the first byte means that the master is to write information to the slave, whereas a Logic 1 means that the master is to read information from the slave after writing the address and repeating the start address. A data transfer takes place until a master initiates a stop condition. A stop condition occurs when SDA transitions from low to high while SCL is held high.

Stop and start conditions can be detected at any stage during the data transfer. If these conditions are asserted out of sequence during normal read and write operations, the ADAU1979 immediately jumps to the idle condition.

Figure 33 and Figure 34 use the following abbreviations:

ACK = acknowledge

No ACK = no acknowledge

Figure 33. I²C Write to ADAU1979 Single Byte

Figure 34. I²C Read from ADAU1979 Single Byte

I²C Read and Write Operations

Figure 35 shows the format of a single-word I²C write operation. Every ninth clock pulse, the ADAU1979 issues an acknowledge by pulling SDA low.

Figure 36 shows the format of a burst mode I²C write sequence. This figure shows an example of a write to sequential single-byte registers. The ADAU1979 increments its address register after every byte because the requested address corresponds to a register or memory area with a 1-byte word length.

Figure 37 shows the format of a single-word I²C read operation. Note that the first R/W bit is 0, indicating a write operation. This is because the address still needs to be written to set up the internal address. After the ADAU1979 acknowledges the receipt of the address, the master must issue a repeated start command

followed by the chip address byte with the R/W bit set to 1 (read). This causes the ADAU1979 SDA to reverse and begin driving data back to the master. The master then responds every ninth pulse with an acknowledge pulse to the ADAU1979.

Figure 38 shows the format of a burst mode I²C read sequence. This figure shows an example of a read from sequential single-byte registers. The ADAU1979 increments its address registers after every byte because the ADAU1979 uses an 8-bit register address.

Figure 35 to Figure 38 use the following abbreviations:

- S = start bit
- P = stop bit
- AM = acknowledge by master
- AS = acknowledge by slave

SPI MODE

By default, the ADAU1979 is in I²C mode. To invoke SPI control mode, pull $\overline{\text{CLATCH}}$ low three times. This is achieved by performing three dummy writes to the SPI port (the ADAU1979 does not acknowledge these three writes, see Figure 39). Beginning with the fourth SPI write, data can be written to or read from the device. The ADAU1979 can be taken out of SPI mode only by a full reset initiated by power cycling the device.

The SPI port uses a 4-wire interface, consisting of the $\overline{\text{CLATCH}}$, $\overline{\text{CCLK}}$, $\overline{\text{CIN}}$, and $\overline{\text{COUT}}$ signals, and it is always a slave port. The $\overline{\text{CLATCH}}$ signal goes low at the beginning of a transaction and high at the end of a transaction. The $\overline{\text{CCLK}}$ signal latches $\overline{\text{COUT}}$ on a low-to-high transition. $\overline{\text{COUT}}$ data is shifted out of the ADAU1979 on the falling edge of $\overline{\text{CCLK}}$ and is clocked into a receiving device, such as a microcontroller, on the $\overline{\text{CCLK}}$ rising edge. The $\overline{\text{CIN}}$ signal carries the serial input data, and the $\overline{\text{COUT}}$ signal carries the serial output data. The $\overline{\text{COUT}}$ signal remains tristated until a read operation is requested. This allows direct connection to other SPI-compatible peripheral $\overline{\text{COUT}}$ ports for sharing the same system controller port. All SPI transactions have the same basic generic control word format, as shown in Table 15. A timing diagram is shown in Figure 3. Write all data MSB first.

Chip Address $\overline{\text{R/W}}$

The LSB of the first byte of an SPI transaction is a $\overline{\text{R/W}}$ bit. This bit determines whether the communication is a read (Logic Level 1) or a write (Logic Level 0). This format is shown in Table 13.

Table 13. SPI Address and $\overline{\text{R/W}}$ Byte Format

Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
0	0	0	0	0	0	0	$\overline{\text{R/W}}$

Table 15. Generic Control Word Format

Byte 0	Byte 1	Byte 2	Byte 3 ¹
Device Address[6:0], $\overline{\text{R/W}}$	Register Address[7:0]	Data[7:0]	Data[7:0]

¹ Continues to end of data.

Register Address

The 8-bit address word is decoded to a location in one of the registers. This address is the location of the appropriate register.

Data Bytes

The number of data bytes varies according to the register being accessed. During a burst mode SPI write, an initial register address is written followed by a continuous sequence of data for consecutive register locations.

A sample timing diagram for a single-word SPI write operation to a register is shown in Figure 40. A sample timing diagram of a single-word SPI read operation is shown in Figure 41. The $\overline{\text{COUT}}$ pin transitions being high-Z to being driven at the beginning of Byte 3. In this example, Byte 0 to Byte 1 contain the device address, the $\overline{\text{R/W}}$ bit, and the register address to be read. Subsequent bytes carry the data from the device.

Standalone Mode

The ADAU1979 can also operate in standalone mode. However, in standalone mode, the boost converter, microphone bias, and diagnostics blocks are powered down. To set the device in standalone mode, pull the SA_MODE pin to IOVDD. In this mode, some pins change functionality to provide more flexibility (see Table 14 for more information).

Table 14. Pin Functionality in Standalone Mode

Pin Function ¹	Setting	Description
ADDR0	0	I ² S SAI format
	1	TDM modes, determined by the SDATAOUT2 pin
ADDR1	0	Master mode SAI

ORDERING GUIDE

Model ^{1, 2}	Temperature Range	Package Description	Package Option
ADAU1979WBCPZ	-40°C to +105°C	40-Lead LFCSP_WQ	CP-40-14
ADAU1979WBCPZ-RL	-40°C to +105°C	40-Lead LFCSP, 13" Tape and Reel	CP-40-14
EVAL-ADAU1979Z		Evaluation Board	

¹ Z = RoHS Compliant Part.

² W = Qualified for Automotive Applications.

AUTOMOTIVE PRODUCTS

The ADAU1979WBCPZ models are available with controlled manufacturing to support the quality and reliability requirements of automotive applications. Note that these automotive models may have specifications that differ from the commercial models; therefore, designers should review the Specifications section of this data sheet carefully. Only the automotive grade products shown are available for use in automotive applications. Contact your local Analog Devices account representative for specific product ordering information and to obtain the specific Automotive Reliability reports for these models.

NOTES

NOTES

I²C refers to a communications protocol originally developed by Philips Semiconductors (now NXP Semiconductors).

Компания «Океан Электроники» предлагает заключение долгосрочных отношений при поставках импортных электронных компонентов на взаимовыгодных условиях!

Наши преимущества:

- Поставка оригинальных импортных электронных компонентов напрямую с производств Америки, Европы и Азии, а так же с крупнейших складов мира;
- Широкая линейка поставок активных и пассивных импортных электронных компонентов (более 30 млн. наименований);
- Поставка сложных, дефицитных, либо снятых с производства позиций;
- Оперативные сроки поставки под заказ (от 5 рабочих дней);
- Экспресс доставка в любую точку России;
- Помощь Конструкторского Отдела и консультации квалифицированных инженеров;
- Техническая поддержка проекта, помощь в подборе аналогов, поставка прототипов;
- Поставка электронных компонентов под контролем ВП;
- Система менеджмента качества сертифицирована по Международному стандарту ISO 9001;
- При необходимости вся продукция военного и аэрокосмического назначения проходит испытания и сертификацию в лаборатории (по согласованию с заказчиком);
- Поставка специализированных компонентов военного и аэрокосмического уровня качества (Xilinx, Altera, Analog Devices, Intersil, Interpoint, Microsemi, Actel, Aeroflex, Peregrine, VPT, Syfer, Eurofarad, Texas Instruments, MS Kennedy, Miteq, Cobham, E2V, MA-COM, Hittite, Mini-Circuits, General Dynamics и др.);

Компания «Океан Электроники» является официальным дистрибьютором и эксклюзивным представителем в России одного из крупнейших производителей разъемов военного и аэрокосмического назначения «JONHON», а так же официальным дистрибьютором и эксклюзивным представителем в России производителя высокотехнологичных и надежных решений для передачи СВЧ сигналов «FORSTAR».

JONHON

«JONHON» (основан в 1970 г.)

Разъемы специального, военного и аэрокосмического назначения:

(Применяются в военной, авиационной, аэрокосмической, морской, железнодорожной, горно- и нефтедобывающей отраслях промышленности)

«FORSTAR» (основан в 1998 г.)

ВЧ соединители, коаксиальные кабели, кабельные сборки и микроволновые компоненты:

(Применяются в телекоммуникациях гражданского и специального назначения, в средствах связи, РЛС, а так же военной, авиационной и аэрокосмической отраслях промышленности).
