- Along with SSTUA32864/66, DDR2 register, provides complete solution for DDR2 DIMMs

## DESCRIPTION:

The CSPUA877A is a PLL based clock driver that acts as a zero delay buffer to distribute one differential clock input pair (CLK,  $\overline{\text{CLK}}$ ) to 10 differential output pairs ( $\overline{\text{Y}}[0:9]$ , Y [0:9]) and one differential pair of feedback clock output (FBOUT,  $\overline{\text{FBOUT}}$ ). External feedback pins (FBIN,  $\overline{\text{FBIN}}$ ) for synchronization of the outputs to the input reference is provided. OE, OS, and AVDD control the power-down and test mode logic. When AVDD is grounded, the PLL is turned off and bypassed for test mode purposes. When the differential clock inputs (CLK,  $\overline{\text{CLK}}$ ) are both at logic low, this device will enter a low power-down mode. In this mode, the receivers are disabled, the PLL is turned off, and the output clock drivers are disabled, resulting in a clock driver current consumption of less than 500 $\mu\text{A}$ .

The CSPUA877A requires no external components and has been optimized for very low phase error, skew, and jitter, while maintaining frequency and duty cycle over the operating voltage and temperature range. The CSPUA877, designed for use in both module assemblies and system motherboard based solutions, provides an optimum high-performance clock source.

The CSPUA877A is available in Commercial Temperature Range (0°C to +70°C). See Ordering Information for details.

## TIMING REQUIREMENTS

Symbol	Parameter	Min.	Max.	Unit
$f_{CLK}$	Operating Clock Frequency <sup>(1,2,5)</sup>	125	410	MHz
	Application Clock Frequency <sup>(1,3,5)</sup>	160	410	MHz
$t_{DC}$	Input Clock Duty Cycle	40	60	%
$t_L$	Stabilization Time <sup>(4)</sup>	—	6	$\mu\text{s}$

## NOTES:

- The PLL will track a spread spectrum clock input.
- Operating clock frequency is the range over which the PLL will lock, but may not meet all timing specifications. To be used only for low speed system debug.
- Application clock frequency is the range over which timing specifications apply.
- Stabilization time is the time required for the integrated PLL circuit to obtain phase lock of its feedback signal to its reference signal after power up. During normal operation, the stabilization time is also the time required for the PLL circuit to obtain phase lock of its feedback signal to its reference signal when CLK and  $\overline{\text{CLK}}$  go to a logic LOW state, enters the power-down mode, and later return to active operation. CLK and  $\overline{\text{CLK}}$  may be left floating after they have been driven LOW for one complete clock cycle.
- Will lock to input frequency as low as 30MHz at room temperature and nominal or higher supply voltage (1.8V - 1.9V).

	SSC Modulation Frequency		30	—	33	KHz
	SSC Clock Input Frequency Deviation		0	—	0.5	%

	PLL Loop Bandwidth (-3dB from unity gain)		2	—	—	MHz

## NOTES:

- There are two different terminations that are used with the above AC tests. The output load shown in figure 1 is used to measure the input and output differential pair cross-voltage only. The output load shown in figure 2 is used to measure all other tests, including input and output slew rates. For consistency, use 50 $\Omega$  equal length cables with SMA connectors on the test board.
- Refers to transition of non-inverting output.
- Period jitter and half-period jitter specifications are separate specifications that must be met independently of each other.
- To eliminate the impact of input slew rates on static phase offset, the input slew rates of reference clock input (CLK,  $\overline{CLK}$ ) and feedback clock input (FBIN,  $\overline{FBIN}$ ) are recommended to be nearly equal. The 2.5V/ns slew rates are shown as a recommended target. Compliance with these nominal values is not mandatory if it can be adequately demonstrated that alternative characteristics meet the requirements of the registered DDR2 DIMM application.
- Static phase offset does not include jitter.
- V<sub>OX</sub> is specified at the DDR DRAM clock input or test load.
- In the frequency range of 271 - 410MHz, the min and max values for t<sub>JIT(PER)</sub> and t<sub>( $\emptyset$ )DYN</sub>, and the max value for tsk(O), must not exceed the corresponding min and max values of the 160 - 270MHz range. Also, the sum of the specified values for | t<sub>JIT(PER)</sub> |, | t<sub>( $\emptyset$ )DYN</sub> |, and tsk(O) must meet the requirement for  $\Sigma t$ (SU), and the sum of the specified values for | t<sub>( $\emptyset$ )DYN</sub> | and tsk(O) must meet the requirement for  $\Sigma t$ (H).
