

# Switching Power Manager with USB On-the-Go + Triple Step-Down DC/DCs

## FEATURES

- Bidirectional Switching Regulator with Bat-Track™ Adaptive Output Control Provides Efficient Charging and a 5V Output for USB On-The-Go
- Bat-Track Control of External High Voltage Step-Down Switching Regulator
- Overvoltage Protection Guards Against Damage
- Instant-On Operation with Discharged Battery
- Triple Step-Down Switching Regulators with I<sup>2</sup>C Adjustable Outputs (1A/400mA/400mA I<sub>OUT</sub>)
- 180mΩ Internal Ideal Diode + External Ideal Diode Controller Powers the Load in Battery Mode
- Li-Ion/Polymer Battery Charger (1.5A Max I<sub>CHG</sub>)
- Battery Float Voltage: 4.2V (LTC3576), 4.1V (LTC3576-1)
- Compact (4mm × 6mm × 0.75mm) 38-Pin QFN Package

## APPLICATIONS

- HDD-Based Media Players
- GPS, PDAs, Digital Cameras, Smart Phones
- Automotive Compatible Portable Electronics

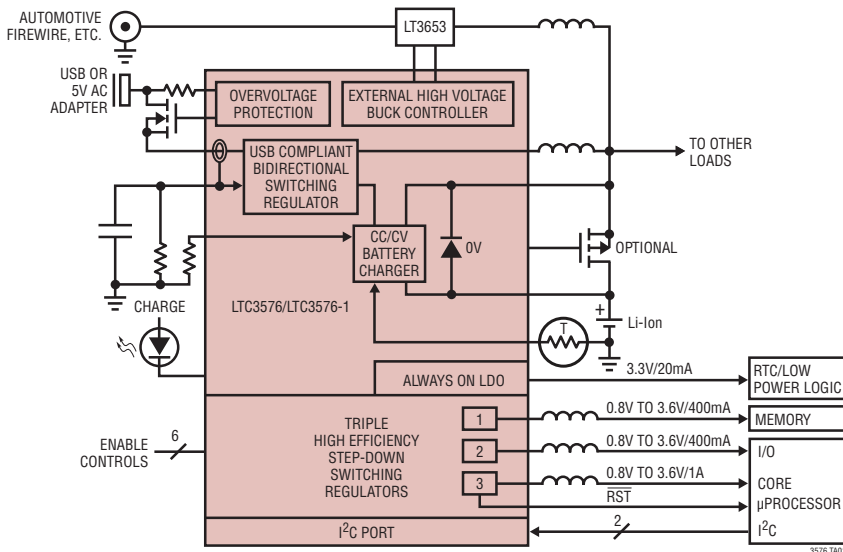

## DESCRIPTION

The LTC®3576/LTC3576-1 are highly integrated power management and battery charger ICs for Li-Ion/Polymer battery applications. They each include a high efficiency, bidirectional switching PowerPath™ manager with automatic load prioritization, a battery charger, an ideal diode, a controller for an external high voltage switching regulator and three general purpose step-down switching regulators with I<sup>2</sup>C adjustable output voltages. The internal switching regulators automatically limit input current for USB compatibility and can also generate 5V at 500mA for USB on-the-go applications when powered from the battery. Both the USB and external switching regulator power paths feature Bat-Track optimized charging to provide maximum power to the application from supplies as high as 38V. An overvoltage circuit protects the LTC3576/LTC3576-1 from damage due to high voltage on the V<sub>BUS</sub> or WALL pins with just two external components. The LTC3576/LTC3576-1 are available in a low profile 38-pin (4mm × 6mm × 0.75mm) QFN package.

## TYPICAL APPLICATION

### High Efficiency PowerPath Manager with Overvoltage Protection and Triple Step-Down Regulator

### PowerPath Switching Regulator Efficiency to System Load (P<sub>VOUT</sub>/P<sub>VBUS</sub>)

# LTC3576/LTC3576-1

## ABSOLUTE MAXIMUM RATINGS

(Notes 1, 2, 3)

$V_{BUS}$ , WALL (Transient) $t < 1\text{ms}$ , Duty Cycle $< 1\%$	–0.3V to 7V
$V_{BUS}$ , WALL (Static), BAT, $V_{IN1}$ , $V_{IN2}$ , $V_{IN3}$ , $V_{OUT}$ , ENOTG, NTC, SDA, SCL, $DV_{CC}$ , RST3, CHRG	–0.3V to 6V
$I_{LIM0}$ , $I_{LIM1}$	–0.3V to $\text{Max}(V_{BUS}, V_{OUT}, \text{BAT}) + 0.3\text{V}$
EN1, EN2, EN3	–0.3V to $V_{OUT} + 0.3\text{V}$
FBx (x = 1, 2, 3)	–0.3V to $V_{INx} + 0.3\text{V}$
$I_{OVSENS}$	10mA
$I_{CLPROG}$	3mA
$I_{CHRG}$ , $I_{RST3}$	50mA
$I_{PROG}$	2mA
$I_{LDO3V3}$	30mA
$I_{SW1}$ , $I_{SW2}$ (Continuous)	600mA
$I_{SW}$ , $I_{SW3}$ , $I_{BAT}$ , $I_{VOUT}$ (Continuous)	2A
Maximum Junction Temperature	125°C
Operating Temperature Range	–40°C to 85°C
Storage Temperature Range	–65°C to 125°C

## PIN CONFIGURATION

## ORDER INFORMATION

LEAD FREE FINISH	TAPE AND REEL	PART MARKING	PACKAGE DESCRIPTION	TEMPERATURE RANGE
LTC3576EUF#PBF	LTC3576EUF#TRPBF	3576	38-Lead (4mm × 6mm) Plastic QFN	–40°C to 85°C
LTC3576EUF-1#PBF	LTC3576EUF-1#TRPBF	35761	38-Lead (4mm × 6mm) Plastic QFN	–40°C to 85°C

Consult LTC Marketing for parts specified with wider operating temperature ranges.

Consult LTC Marketing for information on non-standard lead based finish parts.

Burst Mode is a registered trademark of Linear Technology Corporation.

**Note 1:** Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

**Note 2:** The LTC3576E/LTC3576E-1 are guaranteed to meet performance specifications from  $0^\circ\text{C}$  to  $85^\circ\text{C}$ . Specifications over the  $-40^\circ\text{C}$  to  $85^\circ\text{C}$  operating temperature range are assured by design, characterization and correlation with statistical process controls.

**Note 3:** The LTC3576E/LTC3576E-1 include overtemperature protection that is intended to protect the device during momentary overload conditions. Junction temperature will exceed  $125^\circ\text{C}$  when overtemperature protection is active. Continuous operation above the specified maximum operating junction temperature may impair device reliability.

**Note 4:** Total input current is the sum of quiescent current,  $I_{\text{VBUSQ}}$ , and measured current given by  $V_{\text{CLPROG}}/\text{R}_{\text{CLPROG}} \cdot (h_{\text{CLPROG}} + 1)$ .

**Note 5:** The current limit features of this part are intended to protect the IC from short term or intermittent fault conditions. Continuous operation above the maximum specified pin current rating may result in device degradation or failure.

**Note 6:** The bidirectional switcher's supply current is bootstrapped to  $V_{\text{BUS}}$  and in the application will reflect back to  $V_{\text{OUT}}$  by  $(V_{\text{BUS}}/V_{\text{OUT}}) \cdot 1/\text{efficiency}$ . Total quiescent current is the sum of the current into the  $V_{\text{OUT}}$  pin plus the reflected current.

**Note 7:**  $h_{\text{C}/10}$  is expressed as a fraction of the measured full charge current with indicated PROG resistor.

**Note 8:**  $V_{\text{OUT}}$  not in UVLO.

**Note 9:** FBx above regulation such that regulator is in sleep. Specification does not include resistive divider current reflected back to  $V_{\text{INX}}$ .

**Note 10:** Applies to pulse-skipping and Burst Mode operation only.

**Note 11:** Inductor series resistance adds to open-loop  $\text{R}_{\text{OUT}}$ .

## PIN FUNCTIONS

**CLPROG (Pin 1):** USB Current Limit Program and Monitor Pin. A 1% resistor from CLPROG to ground determines the upper limit of the current drawn or sourced from the  $V_{BUS}$  pins. A precise fraction,  $h_{CLPROG}$ , of the  $V_{BUS}$  current is sent to the CLPROG pin when the PMOS switch of the PowerPath switching regulator is on. The switching regulator delivers power until the CLPROG pin reaches 1.18V in step-down mode and 1.15V in step-up mode. When the switching regulator is in step-down mode, CLPROG is used to regulate the average input current. Several  $V_{BUS}$  current limit settings are available via user input which will typically correspond to the 500mA and 100mA USB specifications. When the switching regulator is in step-up mode (USB on-the-go), CLPROG is used to limit the average output current to 680mA. A multilayer ceramic averaging capacitor or R-C network is required at CLPROG for filtering.

**LDO3V3 (Pin 2):** 3.3V LDO Output Pin. This pin provides a regulated always-on 3.3V supply voltage. LDO3V3 gets its power from  $V_{OUT}$ . It may be used for light loads such as a watchdog microprocessor or real time clock. A 1 $\mu$ F capacitor is required from LDO3V3 to ground. If the LDO3V3 output is not used it should be disabled by connecting it to  $V_{OUT}$ .

**NTCBIAS (Pin 3):** NTC Thermistor Bias Output. If NTC operation is desired, connect a bias resistor between NTCBIAS and NTC, and an NTC thermistor between NTC and GND. To disable NTC operation, connect NTC to GND and leave NTCBIAS open.

**NTC (Pin 4):** Input to the Thermistor Monitoring Circuits. The NTC pin connects to a negative temperature coefficient thermistor, which is typically co-packaged with the battery, to determine if the battery is too hot or too cold to charge. If the battery's temperature is out of range, charging is paused until it re-enters the valid range. A low drift bias resistor is required from NTCBIAS to NTC and a thermistor is required from NTC to ground. To disable NTC operation, connect NTC to GND and leave NTCBIAS open.

**OVGATE (Pin 5):** Overvoltage Protection Gate Output. Connect OVGATE to the gate pin of an external N-channel MOS pass transistor. The source of the transistor should

be connected to  $V_{BUS}$  and the drain should be connected to the product's DC input connector. In the absence of an overvoltage condition, this pin is connected to an internal charge pump capable of creating sufficient overdrive to fully enhance the pass transistor. If an overvoltage condition is detected, OVGATE is brought rapidly to GND to prevent damage to the LTC3576/LTC3576-1. OVGATE works in conjunction with OVSENS to provide this protection.

**OVSENS (Pin 6):** Overvoltage Protection Sense Input. OVSENS should be connected through a 6.2k resistor to the input power connector and the drain of an external N-channel MOS pass transistor. When the voltage on this pin exceeds  $V_{OVCUTOFF}$ , the OVGATE pin will be pulled to GND to disable the pass transistor and protect the LTC3576/LTC3576-1. The OVSENS pin shunts current during an overvoltage transient in order to keep the pin voltage at 6V.

**FB1 (Pin 7):** Feedback Input for Switching Regulator 1. When regulator 1's control loop is complete, this pin serves to 1 of 16 possible set points based on the commanded value from the I<sup>2</sup>C serial port. See Table 4.

**V<sub>IN1</sub> (Pin 8):** Power Input for Switching Regulator 1. This pin will generally be connected to  $V_{OUT}$ . A 1 $\mu$ F MLCC capacitor is recommended on this pin.

**SW1 (Pin 9):** Power Transmission Pin for Switching Regulator 1.

**EN1 (Pin 10):** Logic Input. This logic input pin independently enables switching regulator 1. Active high. This pin is logically ORed with its corresponding bit in the I<sup>2</sup>C serial port. See Table 3. Has a 2 $\mu$ A internal pull-down current source.

**ENOTG (Pin 11):** Logic Input. This logic input pin independently enables the bidirectional switching regulator to step up the voltage on  $V_{OUT}$  and provide a 5V output on  $V_{BUS}$  for USB on-the-go applications. Active high. This pin is logically ORed with its corresponding bit in the I<sup>2</sup>C serial port. See Table 3. Has a 2 $\mu$ A internal pull-down current source.

## PIN FUNCTIONS

**DV<sub>CC</sub> (Pin 12):** Logic Supply for the I<sup>2</sup>C Serial Port. If the serial port is not needed, it can be disabled by grounding DV<sub>CC</sub>. When DV<sub>CC</sub> is grounded, the I<sup>2</sup>C bits are set to their default values. See Table 3.

**SCL (Pin 13):** Clock Input Pin for the I<sup>2</sup>C Serial Port. The I<sup>2</sup>C logic levels are scaled with respect to DV<sub>CC</sub>. If DV<sub>CC</sub> is grounded, the SCL pin is equivalent to the C2, C4 and C6 bits in the I<sup>2</sup>C serial port. SCL in conjunction with SDA determine the operating modes of switching regulators 1, 2 and 3 when DV<sub>CC</sub> is grounded. See Tables 3 and 5. Has a 2μA internal pull-down current source.

**SDA (Pin 14):** Data Input Pin for the I<sup>2</sup>C Serial Port. The I<sup>2</sup>C logic levels are scaled with respect to DV<sub>CC</sub>. If DV<sub>CC</sub> is grounded, the SDA pin is equivalent to the C3, C5 and C7 bits in the I<sup>2</sup>C serial port. SDA in conjunction with SCL determine the operating modes of switching regulators 1, 2 and 3 when DV<sub>CC</sub> is grounded. See Tables 3 and 5. Has a 2μA internal pull-down current source.

**NC (Pin 15):** Unconnected Pin. This pin is not connected internally to the part. It is permissible to tie this pin to V<sub>IN3</sub> in order to make the V<sub>IN3</sub> PCB trace wider.

**V<sub>IN3</sub> (Pin 16):** Power Input for Switching Regulator 3. This pin will generally be connected to V<sub>OUT</sub>. A 1μF MLCC capacitor is recommended on this pin.

**SW3 (Pin 17):** Power Transmission Pin for Switching Regulator 3.

**NC (Pin 18):** Unconnected Pin. This pin is not connected internally to the part. It is permissible to tie this pin to SW3 in order to make the SW3 PCB trace wider.

**EN3 (Pin 19):** Logic Input. This logic input pin independently enables switching regulator 3. Active high. This pin is logically ORed with its corresponding bit in the I<sup>2</sup>C serial port. See Table 3. Has a 2μA internal pull-down current source.

**FB3 (Pin 20):** Feedback Input for Switching Regulator 3. When regulator 3's control loop is complete, this pin serves to 1 of 16 possible set points based on the commanded value from the I<sup>2</sup>C serial port. See Table 4.

**RST3 (Pin 21):** Logic Output. This is an open-drain output which indicates that switching regulator 3 has settled to its final value. It can be used as a power-on reset for the primary microprocessor or to enable the other switching regulators for supply sequencing.

**EN2 (Pin 22):** Logic Input. This logic input pin independently enables switching regulator 2. Active high. This pin is logically ORed with its corresponding bit in the I<sup>2</sup>C serial port. See Table 3. Has a 2μA internal pull-down current source.

**SW2 (Pin 23):** Power Transmission Pin for Switching Regulator 2.

**V<sub>IN2</sub> (Pin 24):** Power Input for Switching Regulator 2. This pin will generally be connected to V<sub>OUT</sub>. A 1μF MLCC capacitor is recommended on this pin.

**FB2 (Pin 25):** Feedback Input for Switching Regulator 2. When regulator 2's control loop is complete, this pin serves to 1 of 16 possible set points based on the commanded value from the I<sup>2</sup>C serial port. See Table 4.

**V<sub>C</sub> (Pin 26):** Bat-Track External Switching Regulator Control Output. This pin drives the V<sub>C</sub> pin of an external Linear Technology step-down switching regulator. An external P-channel MOSFET is sometimes required to provide power to V<sub>OUT</sub> with its gate tied to the  $\overline{\text{ACPR}}$  pin (see the Applications Information section). In concert with WALL and  $\overline{\text{ACPR}}$ , it will regulate V<sub>OUT</sub> to maximize battery charger efficiency.

**WALL (Pin 27):** External Power Source Sense Input. WALL should be connected to the output of the external high voltage switching regulator and to the drain of an external P-channel MOSFET if used. It is used to determine when power is applied to the external regulator. When power is detected,  $\overline{\text{ACPR}}$  is driven low and the USB input is automatically disabled. Pulling this pin above 4.3V enables the V<sub>C</sub> pin.

## PIN FUNCTIONS

**ACPR (Pin 28):** External Power Source Present Output (Active Low).  $\overline{\text{ACPR}}$  indicates that the output of the external high voltage step-down switching regulator is suitable for use by the LTC3576/LTC3576-1. It should be connected to the gate of an external P-channel MOSFET whose source is connected to  $V_{\text{OUT}}$  and whose drain is connected to WALL.  $\overline{\text{ACPR}}$  has a high level of  $V_{\text{OUT}}$  and a low level of GND. The USB bidirectional switcher is disabled when  $\overline{\text{ACPR}}$  is low.

**PROG (Pin 29):** Charge Current Program and Charge Current Monitor Pin. Connecting a 1% resistor from PROG to ground programs the charge current. If sufficient input power is available in constant-current mode, this pin serves to 1V. The voltage on this pin always represents the actual charge current by using the following formula:

$$I_{\text{BAT}} = \frac{V_{\text{PROG}}}{R_{\text{PROG}}} \cdot 1030$$

**CHRG (Pin 30):** Open-Drain Charge Status Output. The  $\overline{\text{CHRG}}$  pin indicates the status of the battery charger. Four possible charger states are represented by  $\overline{\text{CHRG}}$ : charging, not charging, unresponsive battery and battery temperature out of range. In addition,  $\overline{\text{CHRG}}$  is used to indicate whether there is a short-circuit condition on  $V_{\text{BUS}}$  when the bidirectional switching regulator is in step-up mode (on-the-go).  $\overline{\text{CHRG}}$  is modulated at 35kHz and switches between a low and a high duty cycle for easy recognition by either humans or microprocessors. See Table 1.  $\overline{\text{CHRG}}$  requires a pull-up resistor and/or LED to provide indication.

**IDGATE (Pin 31):** Ideal Diode Amplifier Output. This pin controls the gate of an optional external P-channel MOSFET used as an ideal diode between  $V_{\text{OUT}}$  and BAT. The external ideal diode operates in parallel with the internal ideal diode. The source of the P-channel MOSFET should be connected to  $V_{\text{OUT}}$  and the drain should be connected to BAT. If the external ideal diode MOSFET is not used, IDGATE should be left floating.

**BAT (Pin 32):** Single Cell Li-Ion Battery Pin. Depending on available  $V_{\text{BUS}}$  power, a Li-Ion battery on BAT will either deliver power to  $V_{\text{OUT}}$  through the ideal diode or be charged from  $V_{\text{OUT}}$  via the battery charger.

**$V_{\text{OUT}}$  (Pin 33):** Output Voltage of the Bidirectional PowerPath Switching Regulator in step-down mode and Input Voltage of the Battery Charger. The majority of the portable product should be powered from  $V_{\text{OUT}}$ . The LTC3576/LTC3576-1 will partition the available power between the external load on  $V_{\text{OUT}}$  and the internal battery charger. Priority is given to the external load and any extra power is used to charge the battery. An ideal diode from BAT to  $V_{\text{OUT}}$  ensures that  $V_{\text{OUT}}$  is powered even if the load exceeds the allotted power from  $V_{\text{BUS}}$  or if the  $V_{\text{BUS}}$  power source is removed. In on-the-go mode, this pin delivers power to  $V_{\text{BUS}}$  via the SW pin.  $V_{\text{OUT}}$  should be bypassed with a low impedance ceramic capacitor.

**$V_{\text{BUS}}$  (Pins 34, 35):** Power Pins. These pins deliver power to  $V_{\text{OUT}}$  via the SW pin by drawing controlled current from a DC source such as a USB port or DC output wall adapter. In on-the-go mode these pins provide power to external loads. Tie the two  $V_{\text{BUS}}$  pins together at the part and bypass with a low impedance multilayer ceramic capacitor.

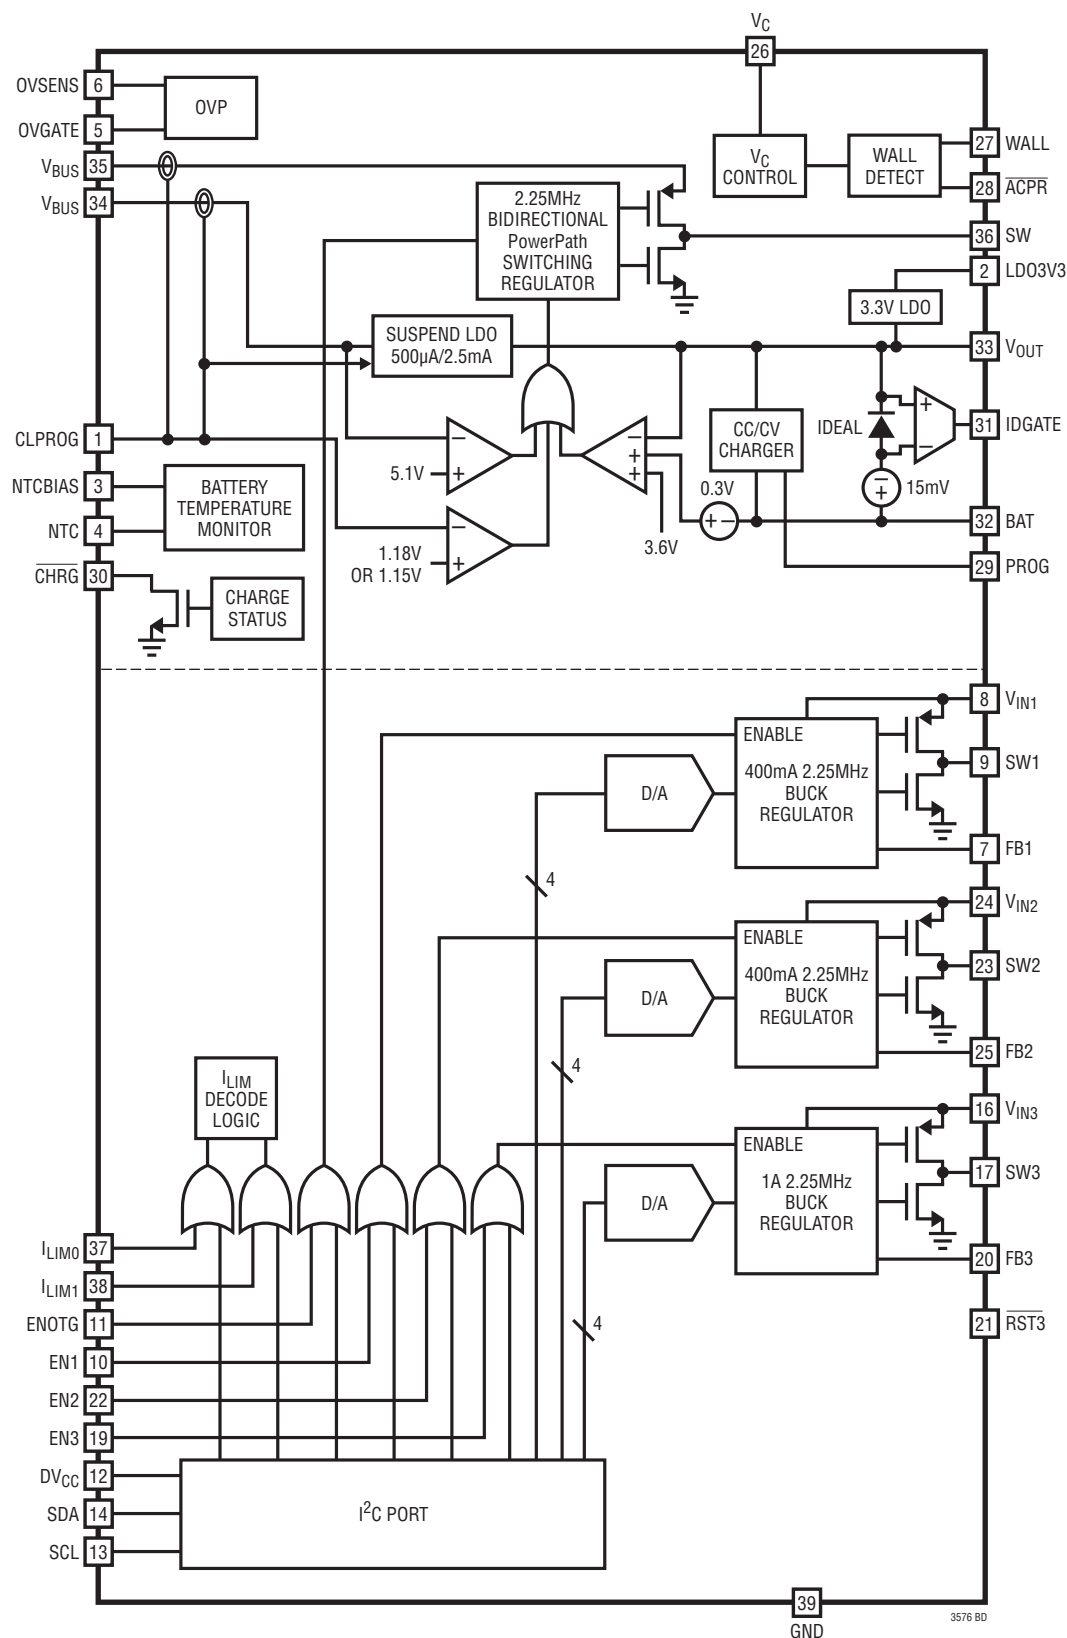

**SW (Pin 36):** The SW pin transfers power between  $V_{\text{BUS}}$  and  $V_{\text{OUT}}$  via the bidirectional switching regulator. See the Applications Information section for a discussion of inductance value and current rating.

**$I_{\text{LIM0}}, I_{\text{LIM1}}$  (Pins 37, 38):**  $I_{\text{LIM0}}$  and  $I_{\text{LIM1}}$  control the current limit of the PowerPath switching regulator. See Table 1. Both the  $I_{\text{LIM0}}$  and  $I_{\text{LIM1}}$  pins are logically ORed with their corresponding bits in the I<sup>2</sup>C serial port. See Tables 3 and 6. Each has a 2μA internal pull-down current source.

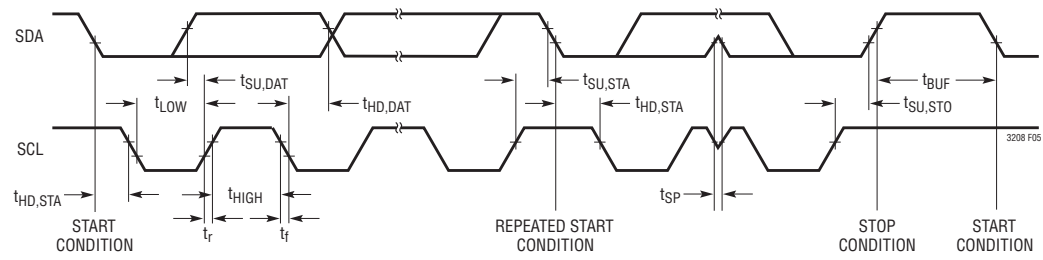

**Exposed Pad (Pin 39):** Ground. The Exposed Pad should be connected to a continuous ground plane on the second layer of the printed circuit board by several vias directly under the LTC3576/LTC3576-1.

BLOCK DIAGRAM

TIMING DIAGRAM

I<sup>2</sup>C WRITE PROTOCOL

## OPERATION

### Introduction

The LTC3576/LTC3576-1 are highly integrated power management ICs designed to make optimal use of the power available from a variety of sources, while minimizing power dissipation and easing thermal budgeting constraints. They include a high efficiency bidirectional PowerPath switching regulator, a controller for an external high voltage step-down switching regulator, a battery charger, an ideal diode, an always-on LDO, an overvoltage protection circuit and three general purpose step-down switching regulators. The entire chip is controlled by either direct digital control or by an I<sup>2</sup>C serial port or both.

The innovative PowerPath architecture ensures that the application is powered immediately after external voltage is applied, even with a completely dead battery, by prioritizing power to the application.

When acting as a step-down converter, the LTC3576/LTC3576-1's bidirectional switching regulator takes power from USB, wall adapters, or other 5V sources and provides power to the application and efficiently charges the battery using Bat-Track. Because power is conserved the LTC3576/LTC3576-1 allow the load current on V<sub>OUT</sub> to exceed the current drawn by the USB port making maximum use of the allowable USB power for battery charging. For USB compatibility the switching regulator includes a precision average input current limit. The PowerPath switching regulator and battery charger communicate to ensure that the average input current never exceeds the USB specifications.

Additionally, the bidirectional switching regulator can also operate as a 5V synchronous step-up converter taking power from V<sub>OUT</sub> and delivering up to 500mA to V<sub>BUS</sub> without the need for any additional external components. This enables systems with USB dual-role transceivers to function as USB on-the-go dual-role devices. True output disconnect and average output current limit features are included for short-circuit protection.

For automotive, firewire, and other high voltage applications, the LTC3576/LTC3576-1 provide Bat-Track control of an external LTC step-down switching regulator to maximize battery charger efficiency and minimize heat production. When power is available from both the USB and an auxiliary input, the auxiliary input is given priority.

The LTC3576/LTC3576-1 contain both an internal 180mΩ ideal diode as well as an ideal diode controller for use with an optional external P-channel MOSFET. The ideal diode(s) from BAT to V<sub>OUT</sub> guarantee that ample power is always available to V<sub>OUT</sub> even if there is insufficient or absent power at V<sub>BUS</sub> or WALL.

An always-on LDO provides a regulated 3.3V from available power at V<sub>OUT</sub>. Drawing very little quiescent current, this LDO will be on at all times and can be used to supply 20mA.

The LTC3576/LTC3576-1 feature an overvoltage protection circuit which is designed to work with an external N-channel MOSFET to prevent damage to their inputs caused by accidental application of high voltage.

To prevent battery drain when a device is connected to a suspended USB port, an LDO from V<sub>BUS</sub> to V<sub>OUT</sub> provides either low power or high power USB suspend current to the application.

The three general purpose switching regulators can be independently enabled either by direct digital control or by operating the I<sup>2</sup>C serial port. Under I<sup>2</sup>C control, all three switching regulators have adjustable set points so that voltages can be reduced when high processor performance is not needed. Along with constant frequency PWM mode, all three switching regulators have automatic Burst Mode operation and LDO modes for significantly reduced quiescent current under light load conditions.

## OPERATION

### Bidirectional PowerPath Switching Regulator— Step-Down Mode

The power delivered from  $V_{BUS}$  to  $V_{OUT}$  is controlled by a 2.25MHz constant frequency bidirectional switching regulator operating in step-down mode.  $V_{OUT}$  drives the combination of the external load (step-down switching regulators 1, 2 and 3) and the battery charger. To meet the maximum USB load specification, the switching regulator contains a measurement and control system that ensures that the average input current remains below the level programmed at CLPROG.

If the combined load does not cause the switching regulator to reach the programmed input current limit,  $V_{OUT}$  will track approximately 0.3V above the battery voltage. By keeping the voltage across the battery charger at this low level, power lost to the battery charger is minimized. Figure 1 shows the power flow in step-down mode.

If the combined external load plus battery charge current is large enough to cause the switching regulator to reach the programmed input current limit, the battery charger will reduce its charge current by precisely the amount necessary to enable the external load to be satisfied. Even if the battery charge current is programmed to exceed the allowable USB current, the USB specification for average input current will not be violated; the battery charger will reduce its current as needed. Furthermore, if the load current at  $V_{OUT}$  exceeds the programmed power from  $V_{BUS}$ , load current will be drawn from the battery via the ideal diode(s) even when the battery charger is enabled.

The current out of CLPROG is a precise fraction of the  $V_{BUS}$  current. When a programming resistor and an averaging capacitor are connected from CLPROG to GND, the voltage on CLPROG represents the average input current of the switching regulator. As the input current approaches the programmed limit, CLPROG reaches 1.18V and power delivered by the switching regulator is held constant.

Figure 1. PowerPath Block Diagram—Power Available from USB/Wall Adapter

3576fb

## OPERATION

The input current limit is programmed by the  $I_{LIM0}$  and  $I_{LIM1}$  pins or by the I<sup>2</sup>C serial port. The input current limit has five possible settings ranging from the USB suspend limit of 500 $\mu$ A up to 1A for wall adapter applications. Two of these settings are specifically intended for use in the 100mA and 500mA USB applications. Refer to Table 1 for current limit settings using the  $I_{LIM0}$  and  $I_{LIM1}$  pins and Table 6 for current limit settings using the I<sup>2</sup>C port.

**Table 1. USB Current Limit Settings Using  $I_{LIM0}$  and  $I_{LIM1}$**

$I_{LIM1}$	$I_{LIM0}$	USB SETTING
0	0	1 $\times$ Mode (USB 100mA Limit)
0	1	10 $\times$ Mode (Wall 1A Limit)
1	0	Low Power Suspend (USB 500 $\mu$ A Limit)
1	1	5 $\times$ Mode (USB 500mA Limit)

When the switching regulator is activated, the average input current will be limited by the CLPROG programming resistor according to the following expression:

$$I_{VBUS} = I_{VBUSQ} + \frac{V_{CLPROG}}{R_{CLPROG}} \cdot (h_{CLPROG} + 1)$$

where  $I_{VBUSQ}$  is the quiescent current of the LTC3576/LTC3576-1,  $V_{CLPROG}$  is the CLPROG servo voltage in current limit,  $R_{CLPROG}$  is the value of the programming resistor and  $h_{CLPROG}$  is the ratio of the measured current at  $V_{BUS}$  to the sample current delivered to CLPROG. Refer to the Electrical Characteristics table for values of  $h_{CLPROG}$ ,  $V_{CLPROG}$  and  $I_{VBUSQ}$ . Given worst-case circuit tolerances, the USB specification for the average input current in 100mA or 500mA mode will not be violated, provided that  $R_{CLPROG}$  is 3.01k or greater.

While not in current limit, the switching regulator's Bat-Track feature will set  $V_{OUT}$  to approximately 300mV above the voltage at BAT. However, if the voltage at BAT is below 3.3V, and the load requirement does not cause the switching regulator to exceed its current limit,  $V_{OUT}$  will regulate at a fixed 3.6V as shown in Figure 2. This instant-on operation will allow a portable product to run immediately when power is applied without waiting for the battery to charge. If the load does exceed the current limit at  $V_{BUS}$ ,  $V_{OUT}$  will range between the no-load voltage and slightly below the battery voltage, indicated by the shaded region of Figure 2.

**Figure 2.  $V_{OUT}$  vs BAT**

For very low-battery voltages, the battery charger acts like a load and, due to limited input power, its current will tend to pull  $V_{OUT}$  below the 3.6V instant-on voltage. To prevent  $V_{OUT}$  from falling below this level, an undervoltage circuit automatically detects that  $V_{OUT}$  is falling and reduces the battery charge current as needed. This reduction ensures that load current and voltage are always prioritized while allowing as much battery charge current as possible. See Battery Charger Over Programming in the Applications Information section.

The voltage regulation loop is compensated by the capacitance on  $V_{OUT}$ . A 10 $\mu$ F MLCC capacitor is required for loop stability. Additional capacitance beyond this value will improve transient response.

An internal undervoltage lockout circuit monitors  $V_{BUS}$  and keeps the switching regulator off until  $V_{BUS}$  rises above 4.30V and is about 200mV above the battery voltage. Hysteresis on the UVLO turns off the regulator if  $V_{BUS}$  falls below 4V or to within 50mV of the battery voltage. When this happens, system power at  $V_{OUT}$  will be drawn from the battery via the ideal diode(s).

### Bidirectional PowerPath Switching Regulator—Step-Up Mode

For USB on-the-go applications, the bidirectional PowerPath switching regulator acts as a step-up converter to deliver power from  $V_{OUT}$  to  $V_{BUS}$ . The power from  $V_{OUT}$  can come from the battery or the output of the external

## OPERATION

Figure 3. PowerPath Block Diagram—USB On-the-Go

high voltage switching regulator. As a step-up converter, the bidirectional switching regulator produces 5V on  $V_{BUS}$  and is capable of delivering at least 500mA. USB on-the-go can be enabled by either the external control pin, ENOTG, or via I<sup>2</sup>C. Figure 3 shows the power flow in step-up mode.

An undervoltage lockout circuit monitors  $V_{OUT}$  and prevents step-up conversion until  $V_{OUT}$  rises above 2.8V. To prevent backdriving of  $V_{BUS}$  when input power is available, the  $V_{BUS}$  undervoltage lockout circuit prevents step-up conversion if  $V_{BUS}$  is greater than 4.3V at the time step-up mode is enabled. The switching regulator is also designed to allow true output disconnect by eliminating body diode conduction of the internal PMOS switch. This allows  $V_{BUS}$  to go to zero volts during a short-circuit condition or while shut down, drawing zero current from  $V_{OUT}$ .

The voltage regulation loop is compensated by the capacitance on  $V_{BUS}$ . A 4.7 $\mu$ F MLCC is required for loop stability. Additional capacitance beyond this value will improve

transient response. The  $V_{BUS}$  voltage has approximately 3% load regulation up to an output current of 500mA. At light loads, the switching regulator goes into Burst Mode operation. The regulator will deliver power to  $V_{BUS}$  until it reaches 5.1V after which the NMOS and PMOS switches shut off. The regulator delivers power again to  $V_{BUS}$  once it falls below 5.1V.

The switching regulator features both peak inductor and average output current limit. The peak current mode architecture limits peak inductor current on a cycle-by-cycle basis. The peak current limit is equal to  $V_{BUS}/2\Omega$  to a maximum of 1.8A so that in the event of a sudden short circuit, the current limit will fold back to a lower value. In step-up mode, the voltage on CLPROG represents the average output current of the switching regulator when a programming resistor and an averaging capacitor are connected from CLPROG to GND. With a 3.01k resistor on CLPROG, the bidirectional switching regulator has an output current limit of 680mA. As the output current ap-

## OPERATION

proaches this limit CLPROG serves to 1.15V and  $V_{BUS}$  falls rapidly to  $V_{OUT}$ . When  $V_{BUS}$  is close to  $V_{OUT}$  there may not be sufficient negative slope on the inductor current when the PMOS switch is on to balance the rise in the inductor current when the NMOS switch is on. This will cause the inductor current to run away and the voltage on CLPROG to rise. When CLPROG reaches 1.2V the switching of the synchronous PMOS is terminated and  $V_{OUT}$  is applied statically to its gate. This ensures that the inductor current will have sufficient negative slope during the time current is flowing to the output. The PMOS will resume switching when CLPROG drops down to 1.15V.

The LTC3576/LTC3576-1 maintain voltage regulation even if  $V_{OUT}$  is above  $V_{BUS}$ . This is achieved by disabling the PMOS switch. The PMOS switch is enabled when  $V_{BUS}$  rises above  $V_{OUT} + 180\text{mV}$  and is disabled when it falls below  $V_{OUT} + 70\text{mV}$  to prevent the inductor current from running away when not in current limit. Since the PMOS no longer acts as a low impedance switch in this mode, there will be more power dissipation within the IC. This will cause a sharp drop in efficiency.

If  $V_{BUS}$  is less than 4V and the PMOS switch is disabled for more than 7.2ms a short-circuit fault will be declared and the part will shut off. The CHRG pin will blink at 35kHz with a duty cycle that varies between 12% and 88% at a 4Hz rate. See Table 2. To re-enable step-up mode, the ENOTG pin or, with ENOTG grounded, the B0 bit in the I<sup>2</sup>C port must be cycled low and then high.

### Bat-Track Auxiliary High Voltage Switching Regulator Control

The WALL,  $\overline{\text{ACPR}}$  and  $V_C$  pins can be used in conjunction with an external high voltage step-down switching regulator such as the LT<sup>®</sup>3480 or the LT3653 to minimize heat production when operating from higher voltage sources, as shown in Figures 1 and 3. Bat-Track control circuitry regulates the external switching regulator's output voltage to the larger of (BAT + 300mV) or 3.6V. This maximizes battery charger efficiency while still allowing instant-on operation when the battery is deeply discharged.

The feedback network of the high voltage regulator should be set to generate an output voltage between 4.5V and 5.5V. When high voltage is applied to the external regulator,

WALL will rise toward this programmed output voltage. When WALL exceeds approximately 4.3V,  $\overline{\text{ACPR}}$  is brought low and the Bat-Track control of the LTC3576/LTC3576-1 overdrives the local  $V_C$  control of the external high voltage step-down switching regulator. Therefore, once the Bat-Track control is enabled, the output voltage is set independent of the switching regulator feedback network.

Bat-Track control provides a significant efficiency advantage over the simple use of a 5V switching regulator output to drive the battery charger. With a 5V output driving  $V_{OUT}$ , battery charger efficiency is approximately:

$$\eta_{\text{TOTAL}} = \eta_{\text{BUCK}} \cdot \frac{V_{\text{BAT}}}{5\text{V}}$$

where  $\eta_{\text{BUCK}}$  is the efficiency of the high voltage switching regulator and 5V is the output voltage of the switching regulator. With a typical switching regulator efficiency of 87% and a typical battery voltage of 3.8V, the total battery charger efficiency is approximately 66%. Assuming a 1A charge current, 1.7W of power is dissipated just to charge the battery!

With Bat-Track, battery charger efficiency is approximately:

$$\eta_{\text{TOTAL}} = \eta_{\text{BUCK}} \cdot \frac{V_{\text{BAT}}}{V_{\text{BAT}} + 0.3\text{V}}$$

With the same assumptions as above, the total battery charger efficiency is approximately 81%. This example works out to less than 1W of power dissipation, or almost 60% less heat.

See the Typical Applications section for complete circuits using the LT3480 and the LT3653 with Bat-Track control.

### Ideal Diode(s) from BAT to $V_{OUT}$

The LTC3576/LTC3576-1 each have an internal ideal diode as well as a controller for an optional external ideal diode. Both the internal and the external ideal diodes are always on and will respond quickly whenever  $V_{OUT}$  drops below BAT.

If the load current increases beyond the power allowed from the switching regulator, additional power will be pulled from the battery via the ideal diode(s). Furthermore, if power to  $V_{BUS}$  (USB or wall adapter) is removed,

## OPERATION

Figure 4. Ideal Diode V-I Characteristics

then all of the application power will be provided by the battery via the ideal diodes. The ideal diode(s) will be fast enough to keep  $V_{OUT}$  from drooping with only the storage capacitance required for the switching regulator. The internal ideal diode consists of a precision amplifier that activates a large on-chip P-channel MOSFET whenever the voltage at  $V_{OUT}$  is approximately 15mV ( $V_{FWD}$ ) below the voltage at BAT. Within the amplifier's linear range, the small-signal resistance of the ideal diode will be quite low, keeping the forward drop near 15mV. At higher current levels, the MOSFET will be in full conduction.

To supplement the internal ideal diode, an external P-channel MOSFET may be added from BAT to  $V_{OUT}$ . The IDGATE pin of the LTC3576/LTC3576-1 drives the gate of the external P-channel MOSFET for automatic ideal diode control. The source of the external P-channel MOSFET should be connected to  $V_{OUT}$  and the drain should be connected to BAT. Capable of driving a 1nF load, the IDGATE pin can control an external P-channel MOSFET transistor having an on-resistance of 30mΩ or lower.

### Suspend LDO

If the LTC3576/LTC3576-1 are configured for USB suspend mode, the bidirectional switching regulator is disabled and the suspend LDO provides power to the  $V_{OUT}$  pin (presuming there is power available to  $V_{BUS}$ ). This LDO will prevent the battery from running down when the portable product has access to a suspended USB port. Regulating at 4.6V, this LDO only becomes active when the switching converter is disabled (suspended). The suspend LDO sends a scaled

copy of the  $V_{BUS}$  current to the CLPROG pin, which will servo to approximately 100mV in this mode. To remain compliant with the USB specification, the input to the LDO is current limited so that it will not exceed the low power or high power suspend specification. If the load on  $V_{OUT}$  exceeds the suspend current limit, the additional current will come from the battery via the ideal diode(s).

### 3.3V Always-On LDO Supply

The LTC3576/LTC3576-1 include a low quiescent current low dropout regulator that is always powered. This LDO can be used to provide power to a system pushbutton controller, standby microcontroller or real time clock. Designed to deliver up to 20mA, the always-on LDO requires at least a 1μF low impedance ceramic bypass capacitor for compensation. The LDO is powered from  $V_{OUT}$ , and therefore will enter dropout at loads less than 20mA as  $V_{OUT}$  falls near 3.3V. If the LDO3V3 output is not used, it should be disabled by connecting it to  $V_{OUT}$ .

### Battery Charger

The LTC3576/LTC3576-1 include a constant-current/constant-voltage battery charger with automatic recharge, automatic termination by safety timer, low voltage trickle charging, bad cell detection and thermistor sensor input for out-of-temperature charge pausing.

### Battery Preconditioning

When a battery charge cycle begins, the battery charger first determines if the battery is deeply discharged. If the battery voltage is below  $V_{TRKL}$ , typically 2.85V, an automatic trickle charge feature sets the battery charge current to 10% of the programmed value. If the low voltage persists for more than 1/2 hour, the battery charger automatically terminates and indicates via the  $\overline{CHRG}$  pin that the battery was unresponsive.

Once the battery voltage is above 2.85V, the charger begins charging in full power constant-current mode. The current delivered to the battery will try to reach  $1030/R_{PROG}$ . Depending on available input power and external load conditions, the battery charger may or may not be able to charge at the full programmed rate. The external load will always be prioritized over the battery charge current.

## OPERATION

Likewise, the USB current limit programming will always be observed and only additional power will be available to charge the battery. When system loads are light, battery charge current will be maximized.

### Charge Termination

The battery charger has a built-in safety timer. When the voltage on the battery reaches the pre-programmed float voltage, the battery charger will regulate the battery voltage and the charge current will decrease naturally. Once the battery charger detects that the battery has reached the float voltage, the four hour safety timer is started. After the safety timer expires, charging of the battery will discontinue and no more current will be delivered.

### Automatic Recharge

After the battery charger terminates, it will remain off drawing only microamperes of current from the battery. If the portable product remains in this state long enough, the battery will eventually self discharge. To ensure that the battery is always topped off, a charge cycle will automatically begin when the battery voltage falls below the recharge threshold which is typically 100mV less than the charger's float voltage. In the event that the safety timer is running when the battery voltage falls below the recharge threshold, it will reset back to zero. To prevent brief excursions below the recharge threshold from resetting the safety timer, the battery voltage must be below the recharge threshold for more than 1ms. The charge cycle and safety timer will also restart if the  $V_{BUS}$  UVLO cycles low and then high (e.g.,  $V_{BUS}$  is removed and then replaced), or if the battery charger is cycled on and off by the I<sup>2</sup>C port.

### Charge Current

The charge current is programmed using a single resistor from PROG to ground. 1/1030th of the battery charge current is sent to PROG which will attempt to servo to 1.000V. Thus, the battery charge current will try to reach 1030 times the current in the PROG pin. The program resistor and the charge current are calculated using the following equation:

$$I_{CHG} = \frac{V_{PROG}}{R_{PROG}} \cdot 1030$$

In either the constant-current or constant-voltage charging modes, the voltage at the PROG pin will be proportional to the actual charge current delivered to the battery. Therefore, the actual charge current can be determined at any time by monitoring the PROG pin voltage and using the following equation:

$$I_{BAT} = \frac{V_{PROG}}{R_{PROG}} \cdot 1030$$

In many cases, the actual battery charge current,  $I_{BAT}$ , will be lower than  $I_{CHG}$  due to limited input power available and prioritization with the system load drawn from  $V_{OUT}$ .

The Battery Charger Flow Chart illustrates the battery charger's algorithm.

### Charge Status Indication

The  $\overline{CHRG}$  pin indicates the status of the battery charger. Four possible states are represented by  $\overline{CHRG}$  which include charging, not charging, unresponsive battery and battery temperature out of range.

The signal at the  $\overline{CHRG}$  pin can be easily recognized as one of the above four states by either a human or a microprocessor. An open-drain output, the  $\overline{CHRG}$  pin can drive an indicator LED through a current limiting resistor for human interfacing or simply a pull-up resistor for microprocessor interfacing.

To make the  $\overline{CHRG}$  pin easily recognized by both humans and microprocessors, the pin is either low for charging, high for not charging, or it is switched at high frequency (35kHz) to indicate the two possible faults, unresponsive battery and battery temperature out of range.

When charging begins,  $\overline{CHRG}$  is pulled low and remains low for the duration of a normal charge cycle. When charging is complete, i.e., the BAT pin reaches the float voltage and the charge current has dropped to one-tenth of the programmed value, the  $\overline{CHRG}$  pin is released (Hi-Z). If a fault occurs, the pin is switched at 35kHz. While switching, its duty cycle is modulated between a high and low value at a very low frequency. The low and high duty cycles are disparate enough to make an LED appear to be on or off thus giving the appearance of "blinking".

OPERATION

Each of the two faults has its own unique “blink” rate for human recognition as well as two unique duty cycles for machine recognition.

The  $\overline{\text{CHRG}}$  pin does not respond to the C/10 threshold if the LTC3576/LTC3576-1 is in  $V_{\text{BUS}}$  current limit. This prevents false end of charge indications due to insufficient power available to the battery charger.

Table 2 illustrates the four possible states of the  $\overline{\text{CHRG}}$  pin when the battery charger is active.

Table 2.  $\overline{\text{CHRG}}$  Signal

STATUS	FREQUENCY	MODULATION (BLINK) FREQUENCY	DUTY CYCLES
Charging	0Hz	0Hz (Low-Z)	100%
Not Charging	0Hz	0Hz (Hi-Z)	0%
NTC Fault	35kHz	1Hz at 50%	6%, 94%
Bad Battery or On-The-Go Short-Circuit Fault	35kHz	4Hz at 50%	12%, 88%

An NTC fault is represented by a 35kHz pulse train whose duty cycle alternates between 6% and 94% at a 1Hz rate. A human will easily recognize the 1Hz rate as a “slow” blinking which indicates the out-of-range battery temperature while a microprocessor will be able to decode either the 6% or 94% duty cycles as an NTC fault.

If a battery is found to be unresponsive to charging (i.e., its voltage remains below 2.85V for 1/2 hour), the  $\overline{\text{CHRG}}$  pin gives the bad battery fault indication. For this fault, a human would easily recognize the 4Hz “fast” blink of the LED while a microprocessor would be able to decode either the 12% or 88% duty cycles as a bad battery fault.

Note that the LTC3576/LTC3576-1 are 3-terminal PowerPath products where system load is always prioritized over battery charging. Due to excessive system load, there may not be sufficient power to charge the battery beyond the trickle charge threshold voltage within the bad battery timeout period. In this case, the battery charger will falsely indicate a bad battery. System software may then reduce the load and reset the battery charger to try again.

In addition to charge status, the  $\overline{\text{CHRG}}$  pin is also used to indicate whether there is a short-circuit condition on  $V_{\text{BUS}}$  when the bidirectional switching regulator is in on-the-go mode. When a short-circuit condition is detected,  $\overline{\text{CHRG}}$  will blink with the same modulation frequency and duty cycle as a bad battery fault. If the charger is on at the same time that on-the-go is enabled, a 4Hz modulation of 12% and 88% duty cycles on  $\overline{\text{CHRG}}$  could indicate a bad battery or a short-circuit fault on  $V_{\text{BUS}}$ . System software should turn off the charger or on-the-go to determine which fault has occurred.

Although very improbable, it is possible that a duty cycle reading could be taken at the bright-dim transition (low duty cycle to high duty cycle). When this happens the duty cycle reading will be precisely 50%. If the duty cycle reading is 50%, system software should disqualify it and take a new duty cycle reading.

NTC Thermistor

The battery temperature is measured by placing a negative temperature coefficient (NTC) thermistor close to the battery pack.

To use this feature connect the NTC thermistor,  $R_{\text{NTC}}$ , between the NTC pin and ground and a bias resistor,  $R_{\text{NOM}}$ , from NTCBIAS to NTC.  $R_{\text{NOM}}$  should be a 1% 200ppm resistor with a value equal to the value of the chosen NTC thermistor at 25°C (R25).

The LTC3576/LTC3576-1 pauses charging when the resistance of the NTC thermistor drops to 0.54 times the value of R25 or approximately 54k for a 100k thermistor. For a Vishay Curve 1 thermistor, this corresponds to approximately 40°C. If the battery charger is in constant voltage (float) mode, the safety timer also pauses until the thermistor indicates a return to a valid temperature. As the temperature drops, the resistance of the NTC thermistor rises. The LTC3576/LTC3576-1 are also designed to pause charging when the value of the NTC thermistor increases to 3.25 times the value of R25. For a Vishay Curve 1 100k thermistor, this resistance, 325k, corresponds to approximately 0°C. The hot and cold comparators each have approximately 3°C of hysteresis to prevent oscillation about the trip point. Grounding the NTC pin disables all NTC functionality.

## OPERATION

### Thermal Regulation

To prevent thermal damage to the LTC3576/LTC3576-1 or surrounding components, an internal thermal feedback loop will automatically decrease the programmed charge current if the die temperature rises to 105°C. This thermal regulation technique protects the LTC3576/LTC3576-1 from excessive temperature due to high power operation or high ambient thermal conditions, and allows the user to push the limits of the power handling capability with a given circuit board design. The benefit of the LTC3576/LTC3576-1 thermal regulation loop is that charge current can be set according to actual conditions rather than worst-case conditions for a given application with the assurance that the charger will automatically reduce the current in worst-case conditions.

### Overvoltage Protection

The LTC3576/LTC3576-1 can protect itself from the inadvertent application of excessive voltage to  $V_{BUS}$  or WALL with just two external components: an N-channel MOSFET and a 6.2k resistor. The maximum safe overvoltage magnitude will be determined by the choice of the external MOSFET and its associated drain breakdown voltage.

The overvoltage protection module consists of two pins. The first, OVSENS, is used to measure the externally applied voltage through an external resistor. The second, OVGATE, is an output used to drive the gate pin of the external MOSFET. When OVSENS is below 6V, an internal charge pump will drive OVGATE to approximately  $1.88 \times \text{OVSENS}$ . This will enhance the N-channel MOSFET and provide a low impedance connection to  $V_{BUS}$  or WALL which will, in turn, power the LTC3576/LTC3576-1. If OVSENS should rise above 6V due to a fault or use of an incorrect wall adapter, OVGATE will be pulled to GND disabling the external MOSFET and therefore protecting downstream circuitry. When the voltage drops below 6V again, the external MOSFET will be re-enabled.

When USB on-the-go is enabled, the bidirectional switching regulator powers up the overvoltage protection circuit through the body diode of the external MOSFET, thus providing protection to the part even when  $V_{BUS}$  is sourcing power. When high voltage is applied to the drain of the external MOSFET,  $V_{BUS}$  will remain at 5V. Once the high

voltage is removed, the drain of the external MOSFET will return to 5V.

The charge pump output on OVGATE has limited output drive capability. Care must be taken to avoid leakage on this pin as it may adversely affect operation.

See the Applications Information section for resistor power dissipation rating calculations, a table of recommended components, and examples of dual-input and reverse input protection.

### I<sup>2</sup>C Interface

The LTC3576/LTC3576-1 may receive commands from a host (master) using the standard 2-wire I<sup>2</sup>C interface. The Timing Diagram shows the timing relationship of the signals on the bus. The two bus lines, SDA and SCL, must be HIGH when the bus is not in use. External pull-up resistors or current sources, such as the LTC1694 I<sup>2</sup>C accelerator, are required on these lines. The LTC3576/LTC3576-1 are receive-only slave devices. The I<sup>2</sup>C control signals, SDA and SCL are scaled internally to the  $DV_{CC}$  supply.  $DV_{CC}$  should be connected to the same power supply as the microcontroller generating the I<sup>2</sup>C signals.

The I<sup>2</sup>C port has an undervoltage lockout on the  $DV_{CC}$  pin. When  $DV_{CC}$  is below approximately 1V, the I<sup>2</sup>C serial port is cleared and switching regulators 1, 2 and 3 are set to full scale.

### Bus Speed

The I<sup>2</sup>C port is designed to be operated at speeds of up to 400kHz. It has built-in timing delays to ensure correct operation when addressed from an I<sup>2</sup>C compliant master device. It also contains input filters designed to suppress glitches should the bus become corrupted.

### Start and Stop Conditions

A bus master signals the beginning of a communication to a slave device by transmitting a START condition. A START condition is generated by transitioning SDA from high to LOW while SCL is HIGH. When the master has finished communicating with the slave, it issues a STOP condition by transitioning SDA from LOW to HIGH while SCL is high. The bus is then free for communication with another I<sup>2</sup>C device.

## OPERATION

### Byte Format

Each byte sent to the LTC3576/LTC3576-1 must be eight bits long followed by an extra clock cycle for the acknowledge bit. The data should be sent to the LTC3576/LTC3576-1 with the most significant bit (MSB) first.

### Acknowledge

The acknowledge signal is used for handshaking between the master and the slave. An acknowledge (active low) generated by the slave (LTC3576/LTC3576-1) lets the master know that the latest byte of information was received. The acknowledge related clock pulse is generated by the master. The master releases the SDA line (HIGH) during the acknowledge clock cycle. The slave-receiver must pull down the SDA line during the acknowledge clock pulse so that it remains a stable LOW during the HIGH period of this clock pulse.

### Slave Address

The address byte consists of the 7-bit address and the read/write (R/W) bit. The LTC3576/LTC3576-1 respond to only one 7-bit address which has been factory programmed to 0001001. The R/W bit is the least significant bit of the address byte. It must be 0 for the LTC3576/LTC3576-1 to recognize the address since they are write only devices. Thus the address byte is 0x12. If the correct seven bit address is given but the R/W bit is 1, the LTC3576/LTC3576-1 will not respond.

### Sub-Addressed Writing

The LTC3576/LTC3576-1 have four command registers for control input. They are accessed by the I<sup>2</sup>C port via a sub-addressed writing system.

Each write to the LTC3576/LTC3576-1 consists of three bytes. The first byte is always the LTC3576/LTC3576-1's write address. The second byte represents the LTC3576/LTC3576-1's sub-address. The sub-address acts as pointer to direct the subsequent data byte within the LTC3576/LTC3576-1. The third byte consists of the data to be written to the location pointed to by the sub-address. The LTC3576/LTC3576-1 contain four sub-addresses at locations 0x00, 0x01, 0x02 and 0x03.

### Bus Write Operation

The master initiates communication with the LTC3576/LTC3576-1 with a START condition and a 7-bit address followed by the R/W bit = 0. If the address matches that of the LTC3576/LTC3576-1, the LTC3576/LTC3576-1 return an acknowledge. The master should then deliver the sub-address. Again the LTC3576/LTC3576-1 acknowledge and the cycle is repeated for the data byte. The data byte is transferred to an internal holding latch upon the return of its acknowledge by the LTC3576/LTC3576-1. This procedure must be repeated for each sub-address that requires new data. After one or more data bytes have been transferred to the LTC3576/LTC3576-1, the master may terminate the communication with a STOP condition. Alternatively, a repeated START condition can be initiated by the master and another chip on the I<sup>2</sup>C bus can be addressed. This cycle can continue indefinitely and the LTC3576/LTC3576-1 remembers the last input of valid data that it received. Once all chips on the bus have been addressed and sent valid data, a global STOP condition can be sent and the LTC3576/LTC3576-1 will update their command latches with the data that they have received.

In certain circumstances the data on the I<sup>2</sup>C bus may become corrupted. In these cases, the LTC3576/LTC3576-1 respond appropriately by preserving only the last set of complete data that they have received. For example, assume the LTC3576/LTC3576-1 have been successfully addressed and are receiving data when a STOP condition mistakenly occurs. The LTC3576/LTC3576-1 will ignore this STOP condition and will not respond until a new START condition, correct address and sub-address, new set of data and STOP condition are transmitted.

Likewise, with only one exception, if the LTC3576/LTC3576-1 were previously addressed and sent valid data but not updated with a STOP, they will respond to any STOP that appears on the bus, independent of the number of repeated STARTs that have occurred. If a repeated START is given and the LTC3576/LTC3576-1 successfully acknowledge their address and sub-address, they will not respond to a STOP until a full byte of the new data has been received and acknowledged.

## OPERATION

### Input Data

Table 3 illustrates the four data bytes that may be written to the LTC3576/LTC3576-1.

The first byte at sub-address 0 controls the servo voltage for switching regulators 1 and 2. The second byte at

sub-address 1 controls the servo voltage of switching regulator 3 and the enable signals for all three switching regulators, as well as the enable signal for the PowerPath switching regulator to power up  $V_{BUS}$  for USB on-the-go. The servo voltages are decoded in Table 4. The default servo voltage is 0.8V.

**Table 3. I<sup>2</sup>C Serial Port Mapping\***

## OPERATION

The third data byte at sub-address 2 controls the operating modes of each switching regulator as well as the input current limit settings. Each switching regulator can be independently set to one of three operating modes listed in Table 5.

**Table 5. General Purpose Switching Regulator Modes**

C7 (SDA)*	C6 (SCL)*	Switching Regulator 1 Mode
C5 (SDA)*	C4 (SCL)*	Switching Regulator 2 Mode
C3 (SDA)*	C2 (SCL)*	Switching Regulator 3 Mode
0	X	Pulse-Skipping Mode
1	0	LDO Mode
1	1	Burst Mode Operation

\*SDA and SCL take on this context only when  $DV_{CC} = 0V$ .

The input current limit settings are decoded according to Table 6. This table indicates the maximum current that will be drawn from the  $V_{BUS}$  pin in the event that the load at  $V_{OUT}$  (battery charger plus system load) exceeds the power available. Any additional power will be drawn from the battery. The start-up state for the input current limit setting is 00 representing the low power 100mA USB setting.

**Table 6. USB Current Limit Settings**

D6	C1 ( $I_{LIM1}$ )*	C0 ( $I_{LIM0}$ )*	USB SETTING
X	0	0	1× Mode (USB 100mA Limit)
X	0	1	10× Mode (Wall 1A Limit)
0	1	0	Low Power Suspend (USB 500µA Limit)
1	1	0	High Power Suspend (USB 2.5mA Limit)
X	1	1	5× Mode (USB 500mA Limit)

\* $I_{LIM1}$  and  $I_{LIM0}$  can only be used to enable the low power suspend mode and are logically ORed with C1 and C0, respectively.

The fourth and final byte of input data at sub-address 3 provides bits for disabling the battery charger and enabling the high power suspend mode current limit of 2.5mA.

### Disabling the I<sup>2</sup>C Port

The I<sup>2</sup>C serial port can be disabled by grounding the  $DV_{CC}$  pin. In this mode, the LTC3576/LTC3576-1 are controlled through the individual logic input pins EN1, EN2, EN3, ENOTG,  $I_{LIM0}$ ,  $I_{LIM1}$ , SDA and SCL. Some functionality is not available in this mode such as the programmability of switching regulators 1, 2 and 3's output voltage, the battery charger disable feature and the high power suspend mode. In this mode, the programmable switching regulators have a fixed servo voltage of 0.8V. Because the SDA and SCL pins have no other context when  $DV_{CC}$  is grounded, these pins are re-mapped to control the switching regulator mode bits C2 to C7. SCL maps to C2, C4 and C6 while SDA maps to C3, C5 and C7.

### RST3 Pin

The  $\overline{RST3}$  pin is an open-drain output used to indicate that switching regulator 3 has been enabled and has reached its final voltage.  $\overline{RST3}$  remains low impedance until regulator 3 reaches 92% of its regulation value.

A 230ms delay is included to allow a system microcontroller ample time to reset itself.  $\overline{RST3}$  may be used as a power-on reset to the microprocessor powered by regulator 3 or may be used to enable regulators 1 and/or 2 for supply sequencing.  $\overline{RST3}$  is an open-drain output and requires a pull-up resistor to the output voltage of regulator 3 or another appropriate power source.

### Shutdown Mode

The bidirectional USB switching regulator in step-down mode is enabled whenever  $V_{BUS}$  is above  $V_{UVLO}$  and the LTC3576/LTC3576-1 are not in one of the two USB suspend modes (500µA or 2.5mA). When power is available from both the USB and auxiliary inputs, the auxiliary input is given priority and the USB switching regulator is disabled.

The ideal diode(s) are enabled at all times and cannot be disabled.

## OPERATION

### Step-Down Switching Regulators

The LTC3576/LTC3576-1 contain three general purpose 2.25MHz step-down constant-frequency current mode switching regulators. Two regulators provide up to 400mA and a third switching regulator can provide up to 1A. All three switching regulators can be programmed for a minimum start-up output voltage of 0.8V and can be used to power a microcontroller core, microcontroller I/O, memory, disk drive or other logic circuitry. All three switching regulators have I<sup>2</sup>C programmable set points for on-the-fly power savings. They also support 100% duty cycle operation (low dropout mode) when their input voltage drops very close to their output voltage. To suit a variety of applications, selectable mode functions can be used to trade off noise for efficiency. Three modes are available to control the operation of the LTC3576/LTC3576-1's general purpose switching regulators. At moderate to heavy loads, the pulse skip mode provides the lowest noise switching solution. At lighter loads, Burst Mode operation or LDO mode may be selected. The switching regulators include soft-start to limit inrush current when powering on, short-circuit current protection and switch node slew limiting circuitry to reduce radiated EMI. No external compensation components are required. The operating mode of the regulators may be set by either I<sup>2</sup>C control or by manual control of the SDA and SCL pins if the I<sup>2</sup>C port is not used. Each converter may be individually enabled by either their external control pins EN1, EN2, EN3 or by the I<sup>2</sup>C port. All three switching regulators have individual programmable feedback servo voltages via I<sup>2</sup>C control. The switching regulator input supplies V<sub>IN1</sub>, V<sub>IN2</sub> and V<sub>IN3</sub> will generally be connected to the system load pin V<sub>OUT</sub>.

### Step-Down Switching Regulator Operating Modes

The LTC3576/LTC3576-1's general purpose switching regulators include three possible operating modes to meet the noise/power needs of a variety of applications.

In pulse-skipping mode, an internal latch is set at the start of every cycle which turns on the main P-channel MOSFET switch. During each cycle, a current comparator compares the peak inductor current to the output of an error amplifier. The output of the current comparator resets the internal latch which causes the main P-channel MOSFET switch to turn off and the N-channel MOSFET synchronous rectifier to turn on. The N-channel MOSFET synchronous rectifier turns off at the end of the 2.25MHz cycle or if the current through the N-channel MOSFET synchronous rectifier drops to zero. Using this method of operation, the error amplifier adjusts the peak inductor current to deliver the required output power. All necessary compensation is internal to the switching regulator requiring only a single ceramic output capacitor for stability. At light loads in PWM mode, the inductor current may reach zero on each pulse which will turn off the N-channel MOSFET synchronous rectifier. In this case, the switch node (SW) goes high impedance and the switch node voltage will "ring". This is discontinuous mode operation, and is normal behavior for a switching regulator. At very light loads in pulse-skipping mode, the switching regulators will automatically skip pulses as needed to maintain output regulation.

At high duty cycles ( $V_{OUTx} > V_{INx}/2$ ) it is possible for the inductor current to reverse, causing the regulator to operate continuously at light loads. This is normal and regulation is maintained, but the supply current will increase to several mA due to continuous switching.

## OPERATION

In Burst Mode operation, the switching regulator automatically switches between fixed frequency PWM operation and hysteretic control as a function of the load current. At light loads, the regulator operates in hysteretic mode and uses a constant current algorithm to control the inductor current. While in Burst Mode operation, the output capacitor is charged to a voltage slightly higher than the regulation point. The step-down switching regulator then goes into sleep mode, during which the output capacitor provides the load current. In sleep mode, most of the regulator's circuitry is powered down, conserving battery power. When the output voltage drops below a pre-determined value, the switching regulator circuitry is powered on and another burst cycle begins. The duration for which the regulator operates in sleep mode depends on the load current. The sleep time decreases as the load current increases. Burst Mode operation provides a significant improvement in efficiency at light loads at the expense of higher output ripple when compared to pulse-skipping mode. At heavy loads Burst Mode operation functions in the same manner as pulse-skipping mode.

Finally, the switching regulators have an LDO mode that gives a DC option for regulating their output voltages. In LDO mode, the switching regulators are converted to linear regulators and deliver continuous power from their SWx pins through their respective inductors. This mode gives the lowest possible output noise as well as low quiescent current at light loads.

The step-down switching regulators allow on-the-fly mode transitions, providing seamless transition between modes even under load. This allows the user to switch back and forth between modes to reduce output ripple or increase low current efficiency as needed.

### Step-Down Switching Regulator Dropout Operation

It is possible for a switching regulator's input voltage,  $V_{INx}$ , to approach its programmed output voltage (e.g., a battery voltage of 3.4V with a programmed output voltage of 3.3V). When this happens, the PMOS switch duty cycle increases until it is turned on continuously at 100%. In this

dropout condition, the respective output voltage equals the regulator's input voltage minus the voltage drops across the internal P-channel MOSFET and the inductor.

### Step-Down Switching Regulator Low Supply Operation

The LTC3576/LTC3576-1 incorporate an undervoltage lockout circuit on  $V_{OUT}$  which shuts down the general purpose switching regulators when  $V_{OUT}$  drops below  $V_{OUT(UVLO)}$ . This UVLO prevents unstable operation.

### Step-Down Switching Regulator Soft-Start Operation

Soft-start is accomplished by gradually increasing the peak inductor current for each switching regulator over a 500 $\mu$ s period. This allows each output to rise slowly, helping minimize the battery surge current. A soft-start cycle occurs whenever a given switching regulator is enabled, or after a fault condition has occurred (thermal shutdown or UVLO). A soft-start cycle is not triggered by changing operating modes. This allows seamless output operation when transitioning between Burst Mode operation, pulse-skipping mode or LDO mode.

### Step-Down Switching Regulator Switching Slew Rate Control

The step-down switching regulators contain new patent pending circuitry to limit the slew rate of the switch node (SWx). This new circuitry is designed to transition the switch node over a period of a couple of nanoseconds, significantly reducing radiated EMI and conducted supply noise.

### Step-Down Switching Regulator in Shutdown

The step-down switching regulators are in shutdown when not enabled for operation. In shutdown, all circuitry in the step-down switching regulator is disconnected from the switching regulator input supply leaving only a few nanoamperes of leakage current. The step-down switching regulator outputs are individually pulled to ground through a 10k resistor on their SWx pins when in shutdown.

## APPLICATIONS INFORMATION

### Bidirectional PowerPath Switching Regulator CLPROG Resistor and Capacitor Selection

As described in the Bidirectional Switching Regulator—Step-Down Mode section, the resistor on the CLPROG pin determines the average  $V_{BUS}$  input current limit when the switching regulator is set to either the 1× mode (USB 100mA), the 5× mode (USB 500mA) or the 10× mode. The  $V_{BUS}$  input current will be comprised of two components, the current that is used to drive  $V_{OUT}$  and the quiescent current of the switching regulator. To ensure that the USB specification is strictly met, both components of the input current should be considered. The Electrical Characteristics table gives the typical values for quiescent currents in all settings as well as current limit programming accuracy. To get as close to the 500mA or 100mA specifications as possible, a precision resistor should be used. Recall that:

$$I_{VBUS} = I_{VBUSQ} + V_{CLPROG}/R_{CLPPROG} \cdot (h_{CLPROG} + 1).$$

An averaging capacitor is required in parallel with the resistor so that the switching regulator can determine the average input current. This capacitor also provides the dominant pole for the feedback loop when current limit is reached. To ensure stability, the capacitor on CLPROG should be 0.1μF or larger.

### Bidirectional PowerPath Switching Regulator Inductor Selection

Because the input voltage range and output voltage range of the PowerPath switching regulator are both fairly narrow, the LTC3576/LTC3576-1 were designed for a specific inductance value of 3.3μH. Some inductors which may be suitable for this application are listed in Table 7.

**Table 7. Recommended PowerPath Inductors for the LTC3576**

### Bidirectional PowerPath Switching Regulator $V_{BUS}$ and $V_{OUT}$ Bypass Capacitor Selection

The type and value of capacitors used with the LTC3576/LTC3576-1 determine several important parameters such as regulator control-loop stability and input voltage ripple. Because the LTC3576/LTC3576-1 use a bidirectional switching regulator between  $V_{BUS}$  and  $V_{OUT}$ , the  $V_{BUS}$  current waveform contains high frequency components. It is strongly recommended that a low equivalent series resistance (ESR) multilayer ceramic capacitor (MLCC) be used to bypass  $V_{BUS}$ . Tantalum and aluminum capacitors are not recommended because of their high ESR. The value of the capacitor on  $V_{BUS}$  directly controls the amount of input ripple for a given load current. Increasing the size of this capacitor will reduce the input ripple.

The inrush current limit specification for USB devices is calculated in terms of the total number of Coulombs needed to charge the  $V_{BUS}$  bypass capacitor to 5V. The maximum inrush charge for USB on-the-go devices is 33μC. This places a limit of 6.5μF of capacitance on  $V_{BUS}$  assuming a linear capacitor. However, most ceramic capacitors have a capacitance that varies with bias voltage. The average capacitance needs to be less than 6.5μF over a 0V to 5V bias voltage range to meet the inrush current limit specification. A 10μF capacitor in a 0805 package, such as the Murata GRM21BR71A106KE51L would be a suitable  $V_{BUS}$  bypass capacitor. If more capacitance is required for better noise performance and stability it should be connected directly to the  $V_{BUS}$  pin when using the overvoltage protection circuit. This extra capacitance will be soft-connected over several milliseconds to limit inrush current and avoid excessive transient voltage drops on  $V_{BUS}$ .

To prevent large  $V_{OUT}$  voltage steps during transient load conditions, it is also recommended that an MLCC be used to bypass  $V_{OUT}$ . The output capacitor is used in the compensation of the switching regulator. At least 10μF with low ESR are required on  $V_{OUT}$ . Additional capacitance will improve load transient performance and stability.

MLCCs typically have exceptional ESR performance. MLCCs combined with a tight board layout and an unbroken ground plane will yield very good performance and low EMI emissions.

## APPLICATIONS INFORMATION

There are MLCCs available with several types of dielectrics each having considerably different characteristics. For example, X7R MLCCs have the best voltage and temperature stability. X5R MLCCs have apparently higher packing density but poorer performance over their rated voltage and temperature ranges. Y5V MLCCs have the highest packing density, but must be used with caution, because of their extreme nonlinear characteristic of capacitance versus voltage. The actual in-circuit capacitance of a ceramic capacitor should be measured with a small AC signal and DC bias as is expected in-circuit. Many vendors specify the capacitance versus voltage with a 1V<sub>RMS</sub> AC test signal and, as a result, over state the capacitance that the capacitor will present in the application. Using similar operating conditions as the application, the user must measure or request from the vendor the actual capacitance to determine if the selected capacitor meets the minimum capacitance that the application requires.

### Step-Down Switching Regulator Output Voltage Programming

All three switching regulators have I<sup>2</sup>C programmable set points and can be programmed for start-up output voltages of at least 0.8V. The full-scale output voltage for each switching regulator is programmed using a resistor divider from the switching regulator output connected to the FBx pins such that:

$$V_{OUTx} = V_{FBx} \left( \frac{R1}{R2} + 1 \right)$$

where V<sub>FBx</sub> ranges from 0.425V to 0.8V. See Figure 5.

Typical values for R1 are in the range of 40k to 1M. The capacitor C<sub>FB</sub> cancels the pole created by feedback resistors and the input capacitance of the FBx pin and also helps

Figure 5. Buck Converter Application Circuit

to improve transient response for output voltages much greater than 0.8V. A variety of capacitor sizes can be used for C<sub>FB</sub> but a value of 10pF is recommended for most applications. Experimentation with capacitor sizes between 2pF and 22pF may yield improved transient response.

### Step-Down Switching Regulator Inductor Selection

Many different sizes and shapes of inductors are available from numerous manufacturers. Choosing the right inductor from such a large selection of devices can be overwhelming, but following a few basic guidelines will make the selection process much simpler.

The general purpose step-down converters are designed to work with inductors in the range of 2μH to 10μH. For most applications a 4.7μH inductor is suggested for the lower current switching regulators 1 and 2 and 2μH is recommended for the higher current switching regulator 3. Larger value inductors reduce ripple current which improves output ripple voltage. Lower value inductors result in higher ripple current and improved transient response time. To maximize efficiency, choose an inductor with a low DC resistance. For a 1.2V output, efficiency is reduced about 2% for 100mΩ series resistance at 400mA load current, and about 2% for 300mΩ series resistance at 100mA load current. Choose an inductor with a DC current rating at least 1.5 times larger than the maximum load current to ensure that the inductor does not saturate during normal operation. If output short circuit is a possible condition, the inductor should be rated to handle the maximum peak current specified for the step-down converters. Different core materials and shapes will change the size/current and price/current relationship of an inductor. Toroid or shielded pot cores in ferrite or Permalloy materials are small and don't radiate much energy, but generally cost more than powdered iron core inductors with similar electrical characteristics. Inductors that are very thin or have a very small volume typically have much higher core and DCR losses, and will not give the best efficiency. The choice of which style inductor to use often depends more on the price vs size, performance and any radiated EMI requirements than on what the LTC3576/LTC3576-1 require to operate.

## APPLICATIONS INFORMATION

The inductor value also has an effect on Burst Mode operation. Lower inductor values will cause the Burst Mode operation switching frequency to increase.

Table 8 shows several inductors that work well with the LTC3576/LTC3576-1's general purpose regulators. These inductors offer a good compromise in current rating, DCR and physical size. Consult each manufacturer for detailed information on their entire selection of inductors.

### Step-Down Switching Regulator Input/Output Bypass Capacitor Selection

Low ESR (equivalent series resistance) MLCCs should be used at each switching regulator output as well as at each switching regulator input supply ( $V_{INX}$ ). Only X5R or X7R ceramic capacitors should be used because they retain their capacitance over wider voltage and temperature ranges than other ceramic types. A 10μF output capaci-

tor is sufficient for most applications. For good transient response and stability the output capacitor should retain at least 4μF of capacitance over operating temperature and bias voltage. Each switching regulator input supply should be bypassed with a 1μF capacitor. Consult with capacitor manufacturers for detailed information on their selection and specifications of ceramic capacitors. Many manufacturers now offer very thin (<1mm tall) ceramic capacitors ideal for use in height-restricted designs. Table 9 shows a list of several ceramic capacitor manufacturers.

### Overvoltage Protection

$V_{BUS}$  can be protected from overvoltage damage with two additional components, a resistor R1 and an N-channel MOSFET MN1, as shown in Figure 6. Suitable choices for MN1 are listed in Table 10.

**Table 10. Recommended N-channel MOSFETs for the Overvoltage Protection Circuit**

PART NUMBER	BVDSS	R <sub>ON</sub>	PACKAGE
Si1472DH	30V	82mΩ	SC70-6
Si2302ADS	20V	60mΩ	SOT-23
Si2306BDS	30V	65mΩ	SOT-23
Si2316BDS	30V	80mΩ	SOT-23
IRLML2502	20V	35mΩ	SOT-23
FDN372S	30V	50mΩ	SOT-23
NTLJS4114N	30V	35mΩ	WDFN6

R1 is a 6.2k resistor and must be rated for the power dissipated during maximum overvoltage. In an overvoltage condition the OVSENS pin will be clamped at 6V. R1 must be sized appropriately to dissipate the resultant power. For example, a 1/10W 6.2k resistor can have at most  $\sqrt{P_{MAX} \cdot 6.2k\Omega} = 25V$  applied across its terminals. With the 6V at OVSENS, the maximum overvoltage magnitude that this resistor can withstand is 31V. A 1/4W 6.2k resistor raises this value to 45V. OVSENS's absolute maximum current rating of 10mA imposes an upper limit of 68V protection.

## APPLICATIONS INFORMATION

Figure 6. Overvoltage Protection

Figure 7. Dual-Input Overvoltage Protection

It is possible to protect both  $V_{BUS}$  and WALL from overvoltage damage with several additional components, as shown in Figure 7. Schottky diodes D1 and D2 pass the larger of V1 and V2 to R1 and OVSENS. If either V1 or V2 exceeds 6V plus  $V_F$  (Schottky), OVGATE will be pulled to GND and both the WALL and USB inputs will be protected. Each input is protected up to the drain-source breakdown, BVDSS, of MN1 and MN2. R1 must also be rated for the power dissipated during maximum overvoltage.

### Reverse Voltage Protection

The LTC3576/LTC3576-1 can also be easily protected against the application of reverse voltages, as shown in Figure 8. D1 and R1 are necessary to limit the maximum  $V_{GS}$  seen by MP1 during positive overvoltage events. D1's breakdown voltage must be safely below MP1's BVGS. The circuit shown in Figure 8 offers forward voltage protection up to MN1's BVDSS and reverse voltage protection up to MP1's BVDSS.

### Battery Charger Over Programming

The USB high power specification allows for up to 2.5W to be drawn from the USB port. The LTC3576/LTC3576-1's bidirectional switching regulator in step-down mode

Figure 8. Dual Polarity Voltage Protection

transforms the voltage at  $V_{BUS}$  to a voltage just above the level at BAT, while limiting power to less than the amount programmed at CLPROG. The charger should be programmed (with the PROG pin) to deliver the maximum safe charging current without regard to the USB specifications. If there is insufficient current available to charge the battery at the programmed rate, it will reduce charge current until the system load on  $V_{OUT}$  is satisfied and the  $V_{BUS}$  current limit is satisfied. Programming the charger for more current than is available will not cause the average input current limit to be violated. It will merely allow the battery charger to make use of all available power to charge the battery as quickly as possible, and with minimal dissipation within the charger.

### Battery Charger Stability Considerations

The LTC3576/LTC3576-1's battery charger contains both a constant-voltage and a constant-current control loop. The constant-voltage loop is stable without any compensation when a battery is connected with low impedance leads. Excessive lead length, however, may add enough series inductance to require a bypass capacitor of at least 1 $\mu$ F from BAT to GND.

High value, low ESR MLCCs reduce the constant-voltage loop phase margin, possibly resulting in instability. Up to 22 $\mu$ F may be used in parallel with a battery, but larger capacitors should be decoupled with 0.2 $\Omega$  to 1 $\Omega$  of series resistance.

Furthermore, a 100 $\mu$ F MLCC in series with a 0.3 $\Omega$  resistor from BAT to GND is required to prevent oscillation when the battery is disconnected.

In constant-current mode, the PROG pin is in the feedback loop rather than the battery voltage. Because of the additional pole created by any PROG pin capacitance,

## APPLICATIONS INFORMATION

capacitance on this pin must be kept to a minimum. With no additional capacitance on the PROG pin, the charger is stable with program resistor values as high as 25k. However, additional capacitance on this node reduces the maximum allowed program resistor. The pole frequency at the PROG pin should be kept above 100kHz. Therefore, if the PROG pin has a parasitic capacitance,  $C_{\text{PROG}}$ , the following equation should be used to calculate the maximum resistance value for  $R_{\text{PROG}}$ :

$$R_{\text{PROG}} \leq \frac{1}{2\pi \cdot 100\text{kHz} \cdot C_{\text{PROG}}}$$

### Alternate NTC Thermistors and Biasing

The LTC3576/LTC3576-1 provide temperature qualified charging if a grounded thermistor and a bias resistor are connected to NTC. By using a bias resistor whose value is equal to the room temperature resistance of the thermistor ( $R_{25}$ ) the upper and lower temperatures are pre-programmed to approximately 40°C and 0°C respectively assuming a Vishay Curve 1 thermistor.

The upper and lower temperature thresholds can be adjusted by either a modification of the bias resistor value or by adding a second adjustment resistor to the circuit. If only the bias resistor is adjusted, then either the upper or the lower threshold can be modified but not both. The other trip point will be determined by the characteristics

of the thermistor. Using the bias resistor in addition to an adjustment resistor, both the upper and the lower temperature trip points can be independently programmed with the constraint that the difference between the upper and lower temperature thresholds cannot decrease. Examples of each technique are given below.

NTC thermistors have temperature characteristics which are indicated on resistance-temperature conversion tables. The Vishay-Dale thermistor NTHS0603N011-N1003F, used in the following examples, has a nominal value of 100k and follows the Vishay Curve 1 resistance-temperature characteristic.

In the explanation below, the following notation is used.

$R_{25}$  = Value of the Thermistor at 25°C

$R_{\text{NTC|COLD}}$  = Value of thermistor at the cold trip point

$R_{\text{NTC|HOT}}$  = Value of the thermistor at the hot trip point

$r_{\text{COLD}}$  = Ratio of  $R_{\text{NTC|COLD}}$  to  $R_{25}$

$r_{\text{HOT}}$  = Ratio of  $R_{\text{NTC|HOT}}$  to  $R_{25}$

$R_{\text{NOM}}$  – Primary thermistor bias resistor (see Figure 9)

$R_1$  = Optional temperature range adjustment resistor (see Figure 10)

Figure 9. Standard NTC Configuration

Figure 10. Modified NTC Configuration

3576fb

## APPLICATIONS INFORMATION

The trip points for the LTC3576/LTC3576-1's temperature qualification are internally programmed at  $0.349 \cdot \text{NTCBIAS}$  for the hot threshold and  $0.765 \cdot \text{NTCBIAS}$  for the cold threshold.

Therefore, the hot trip point is set when:

$$\frac{R_{\text{NTC|HOT}}}{R_{\text{NOM}} + R_{\text{NTC|HOT}}} \cdot \text{NTCBIAS} = 0.349 \cdot \text{NTCBIAS}$$

And the cold trip point is set when:

$$\frac{R_{\text{NTC|COLD}}}{R_{\text{NOM}} + R_{\text{NTC|COLD}}} \cdot \text{NTCBIAS} = 0.765 \cdot \text{NTCBIAS}$$

Solving these equations for  $R_{\text{NTC|COLD}}$  and  $R_{\text{NTC|HOT}}$  results in the following:

$$R_{\text{NTC|HOT}} = 0.536 \cdot R_{\text{NOM}}$$

and

$$R_{\text{NTC|COLD}} = 3.25 \cdot R_{\text{NOM}}$$

By setting  $R_{\text{NOM}}$  equal to  $R_{25}$ , the above equations result in  $r_{\text{HOT}} = 0.536$  and  $r_{\text{COLD}} = 3.25$ . Referencing these ratios to the Vishay Resistance-Temperature Curve 1 chart gives a hot trip point of about  $40^\circ\text{C}$  and a cold trip point of about  $0^\circ\text{C}$ . The difference between the hot and cold trip points is approximately  $40^\circ\text{C}$ .

By using a bias resistor,  $R_{\text{NOM}}$ , different in value from  $R_{25}$ , the hot and cold trip points can be moved in either direction. The temperature span will change somewhat due to the nonlinear behavior of the thermistor. The following equations can be used to calculate a new value for the bias resistor:

$$R_{\text{NOM}} = \frac{r_{\text{HOT}}}{0.536} \cdot R_{25}$$

$$R_{\text{NOM}} = \frac{r_{\text{COLD}}}{3.25} \cdot R_{25}$$

where  $r_{\text{HOT}}$  and  $r_{\text{COLD}}$  are the resistance ratios at the desired hot and cold trip points. Note that these equations are linked. Therefore, only one of the two trip points can be chosen, the other is determined by the default ratios designed in the IC. Consider an example where a  $60^\circ\text{C}$  hot trip point is desired.

From the Vishay Curve 1 R-T characteristics,  $r_{\text{HOT}}$  is 0.2488 at  $60^\circ\text{C}$ . Using the above equation,  $R_{\text{NOM}}$  should be set to 46.4k. With this value of  $R_{\text{NOM}}$ ,  $r_{\text{COLD}}$  is 1.436 and the cold trip point is about  $16^\circ\text{C}$ . Notice that the span is now  $44^\circ\text{C}$  rather than the previous  $40^\circ\text{C}$ . This is due to the decrease in "temperature gain" of the thermistor as absolute temperature increases.

The upper and lower temperature trip points can be independently programmed by using an additional bias resistor as shown in Figure 10. The following formulas can be used to compute the values of  $R_{\text{NOM}}$  and  $R_1$ :

$$R_{\text{NOM}} = \frac{r_{\text{COLD}} - r_{\text{HOT}}}{2.714} \cdot R_{25}$$

$$R_1 = 0.536 \cdot R_{\text{NOM}} - r_{\text{HOT}} \cdot R_{25}$$

For example, to set the trip points to  $0^\circ\text{C}$  and  $45^\circ\text{C}$  with a Vishay Curve 1 thermistor choose:

$$R_{\text{NOM}} = \frac{3.266 - 0.4368}{2.714} \cdot 100\text{k} = 104.2\text{k}$$

the nearest 1% value is 105k:

$$R_1 = 0.536 \cdot 105\text{k} - 0.4368 \cdot 100\text{k} = 12.6\text{k}$$

the nearest 1% value is 12.7k. The final solution is shown in Figure 10 and results in an upper trip point of  $45^\circ\text{C}$  and a lower trip point of  $0^\circ\text{C}$ .

### Hot Plugging and USB Inrush Current Limiting

The overvoltage protection circuit provides inrush current limiting due to the long time it takes for OVGATE to fully enhance the N-channel MOSFET. This prevents the current from building up in the cable too quickly thus dampening out any resonant overshoot on  $V_{\text{BUS}}$ . It is possible to observe voltage overshoot on  $V_{\text{BUS}}$  when connecting the LTC3576/LTC3576-1 to a lab power supply if the overvoltage protection circuit is not used. This overshoot is caused by the inductance of the long leads from the power supply to  $V_{\text{BUS}}$ . Twisting the wires together from the supply to  $V_{\text{BUS}}$  can greatly reduce the parasitic inductance of these long leads keeping the voltage at  $V_{\text{BUS}}$  to safe levels. USB cables are generally manufactured with the power leads in close proximity, and thus have fairly low parasitic inductance.

## APPLICATIONS INFORMATION

### Hot Plugging and USB On-the-Go

If there is more than 4.3V on  $V_{BUS}$  when on-the-go is enabled, the bidirectional switching regulator will not try to drive  $V_{BUS}$ . If USB on-the-go is enabled and an external supply is then connected to  $V_{BUS}$ , one of three things will happen depending on the properties of the external supply. If the external supply has a regulation voltage higher than 5.1V, the bidirectional switching regulator will stop switching and  $V_{BUS}$  will be held at the regulation voltage of the external supply. If the external supply has a lower regulation voltage and is capable of only sourcing current then  $V_{BUS}$  will be regulated to 5.1V. The external supply will not source current to  $V_{BUS}$ .

For a supply that can also sink current and has a regulation voltage less than 5.1V, the bidirectional switching regulator will source current into the external supply in an attempt to bring  $V_{BUS}$  up to 5.1V. As long as the external supply holds  $V_{BUS}$  to more than 4V or  $V_{OUT} + 70\text{mV}$ , the bidirectional switching regulator will source up to 680mA into the supply. If  $V_{BUS}$  is held to a voltage that is less than 4V and  $V_{OUT} + 70\text{mV}$  then the short circuit timer will shut off the switching regulator after 7.2ms. The  $\overline{\text{CHRG}}$  pin will then blink indicating a short circuit current fault.

### $V_{BUS}$ Bypass Capacitance and USB On-The-Go Session Request Protocol

When two on-the-go devices are connected, one will be the A device and the other will be the B device depending on whether the device is connected to a micro A or micro B plug. The A device provides power to the B device and starts as the host. To prolong battery life, the A device can power down  $V_{BUS}$  when the bus is not being used. If the A device has powered down  $V_{BUS}$ , the B device can request the A device to power up  $V_{BUS}$  and start a new session using the session request protocol (SRP). The SRP consists of data-line pulsing and  $V_{BUS}$  pulsing. The B device must first pulse the  $D^+$  or  $D^-$  data line. The B device must then pulse  $V_{BUS}$  only if the A device does not respond to the data-line pulse. The A device is required to respond to only one of the pulsing methods. A devices that never power down  $V_{BUS}$  are not required to respond to the SRP.

For  $V_{BUS}$  pulsing, the limit on the  $V_{BUS}$  capacitance on the A device allows a B device to differentiate between a powered down on-the-go device and a powered down standard host. The B device will send out a pulse of current that will raise  $V_{BUS}$  to a voltage between 2.1V and 5.25V if connected to an on-the-go A device which must have no more than 6.5 $\mu\text{F}$ . An on-the-go A device must drive  $V_{BUS}$  as soon as the current pulse raises  $V_{BUS}$  above 2.1V if the device is capable of responding to  $V_{BUS}$  pulsing.

This same current pulse must not raise  $V_{BUS}$  any higher than 2V when connected to a standard host which must have at least 96 $\mu\text{F}$ . The 96 $\mu\text{F}$  for a standard host represents the minimum capacitance with  $V_{BUS}$  between 4.75V and 5.25V. Since the SRP pulse must not drive  $V_{BUS}$  greater than 2V, the capacitance seen at these voltage levels can be greater than 96 $\mu\text{F}$ , especially if MLCCs are used. Therefore, the 96 $\mu\text{F}$  represents a lower bound on the standard host bypass capacitance for determining the amplitude and duration of the current pulse. More capacitance will only decrease the maximum level that  $V_{BUS}$  will rise to for a given current pulse.

Figure 11 shows an on-the-go device using the LTC3576/LTC3576-1 acting as the A device. Additional capacitance can be placed on the  $V_{BUS}$  pin of the LTC3576/LTC3576-1 when using the overvoltage protection circuit. A B device may not be able to distinguish between a powered down LTC3576/LTC3576-1 with overvoltage protection and a powered down standard host because of this extra capacitance. In addition, if the SRP pulse raises  $V_{BUS}$  above its UVLO threshold of 4.3V the LTC3576/LTC3576-1 will assume input power is available and will not attempt to drive  $V_{BUS}$ . Therefore, it is recommended that an on-the-go device using the LTC3576/LTC3576-1 respond to data-line pulsing.

When an on-the-go device using the LTC3576/LTC3576-1 becomes the B device, as in Figure 12, it must send out a data line pulse followed by a  $V_{BUS}$  pulse to request a session from the A device. The on-the-go device designer can choose how much capacitance will be placed on the  $V_{BUS}$  pin of the LTC3576/LTC3576-1 and then generate a  $V_{BUS}$  pulse that can distinguish between a powered

Figure 12. LTC3576/LTC3576-1 as the B Device

down on-the-go A device and a powered down standard host. A suitable pulse can be generated because of the disparity in the bypass capacitances of an on-the-go A device and a standard host even if there is somewhat more than  $6.5\mu\text{F}$  capacitance connected to the  $V_{\text{BUS}}$  pin of the LTC3576/LTC3576-1.

### Board Layout Considerations

The Exposed Pad on the backside of the LTC3576/LTC3576-1 package must be securely soldered to the PC board ground. This is the primary ground pin in the package, and it serves as the return path for both the control circuitry and the N-channel MOSFET switches.

Furthermore, due to its high frequency switching circuitry, it is imperative that the input capacitor, inductor, and output capacitor be as close to the LTC3576/LTC3576-1 as possible and that there be an unbroken ground plane under the LTC3576/LTC3576-1 and all of their external

high frequency components. High frequency currents, such as the  $V_{\text{BUS}}$ ,  $V_{\text{IN1}}$ ,  $V_{\text{IN2}}$  and  $V_{\text{IN3}}$  currents tend to find their way on the ground plane along a mirror path directly beneath the incident path on the top of the board. If there are slits or cuts in the ground plane due to other traces on that layer, the current will be forced to go around the slits. If high frequency currents are not allowed to flow back through their natural least-area path, excessive voltage will build up and radiated emissions will occur (see Figure 13). There should be a group of vias directly under the grounded backside leading directly down to an internal ground plane. To minimize parasitic inductance, the ground plane should be as close as possible to the top plane of the PC board (layer 2).

The IDGATE pin for the external ideal diode controller has extremely limited drive current. Care must be taken to minimize leakage to adjacent PC board traces.  $100\text{nA}$  of leakage from this pin will introduce an additional offset to

## APPLICATIONS INFORMATION

the ideal diode of approximately 10mV. To minimize leakage, the trace can be guarded on the PC board by surrounding it with  $V_{OUT}$  connected metal, which should generally be less than one volt higher than  $IDGATE$ .

When laying out the printed circuit board, the following checklist should be used to ensure proper operation of the LTC3576/LTC3576-1:

1. The Exposed Pad of the package (Pin 39) should connect directly to a large ground plane to minimize thermal and electrical impedance.
2. The traces connecting  $V_{BUS}$ ,  $V_{IN1}$ ,  $V_{IN2}$ ,  $V_{IN3}$  and  $V_{IN}$  of the external step-down switching regulator to their respective decoupling capacitors should be as short as possible. The GND side of these capacitors should connect directly to the ground plane of the part. These capacitors provide the AC current to the internal power MOSFETs and their drivers. It is critical to minimize inductance from these capacitors to the LTC3576/LTC3576-1 and external step-down switching regulator.
3. Connections between the step-down switching regulator (both internal and external) inductors and their respective output capacitors should be kept as short as possible. Use area fills whenever possible. This also applies to the PowerPath switching regulator inductor and the output capacitor on  $V_{OUT}$ . The GND side of the output capacitors should connect directly to the thermal ground plane of the part.
4. The switching power traces connecting SW, SW1, SW2, SW3 and the switch node of the external step-down switching regulator to their respective inductors should be minimized to reduce radiated EMI and parasitic coupling. Due to the large voltage swing of the switching nodes, sensitive nodes such as the feedback nodes (FB1, FB2 and FB3) should be kept far away or shielded from the switching nodes or poor performance could result.
5. Keep the feedback pin traces (FB1, FB2, FB3 and FB of the external step-down switching regulator) as short as possible. Minimize any parasitic capacitance between the feedback traces and any switching node (i.e., SW, SW1, SW2, SW3 and logic signals). If necessary shield the feedback nodes with a GND trace
6. Connect  $V_{IN1}$ ,  $V_{IN2}$  and  $V_{IN3}$  to  $V_{OUT}$  through a short low impedance trace.

**Component List:**

- C1: MURATA GRM21BR7A106KE51L
- C3: TAIYO YUDEN JMK212BJ226MG
- L1: COILCRAFT LPS4018-332LM
- L2, L3: TOKO 1098AS-4R7M
- L4: TOKO 1098AS-2R0M

**Pin Connections:**

- Pin 35: VBUS
- Pin 34: VBUS
- Pin 5: OVGATE
- Pin 6: OVSNS
- Pin 3: NTCBIAS
- Pin 4: NTC
- Pin 29: PROG
- Pin 1: CLPROG
- Pin 2: LD03V3
- Pin 12: DVCC
- Pin 30: CHRG
- Pin 13, 14: I2C
- Pin 10: EN1
- Pin 22: EN2
- Pin 19: EN3
- Pin 11: ENOTG
- Pin 37: I\_LIM0
- Pin 38: I\_LIM1
- Pin 26: V\_C
- Pin 27: WALL
- Pin 28: ACPR
- Pin 36: SW
- Pin 33: VOUT
- Pin 31: IDGATE
- Pin 32: BAT
- Pin 8: V\_IN1
- Pin 9: SW1
- Pin 7: FB1
- Pin 24: V\_IN2
- Pin 23: SW2
- Pin 25: FB2
- Pin 16: V\_IN3
- Pin 17: SW3
- Pin 20: FB3
- Pin 21: RST3

**Output Voltages and Currents:**

- TO OTHER LOADS: 1.76V TO 3.3V, 400mA
- MEMORY: 1.76V TO 3.3V, 400mA
- I/O: 1.61V TO 3.03V, 400mA
- MICROPROCESSOR: 0.8V TO 1.51V, 1A
- CORE: 0.8V TO 1.51V, 1A
- POR: 0.8V TO 1.51V, 1A

Компания «Океан Электроники» предлагает заключение долгосрочных отношений при поставках импортных электронных компонентов на взаимовыгодных условиях!

Наши преимущества:

- Поставка оригинальных импортных электронных компонентов напрямую с производств Америки, Европы и Азии, а так же с крупнейших складов мира;
- Широкая линейка поставок активных и пассивных импортных электронных компонентов (более 30 млн. наименований);
- Поставка сложных, дефицитных, либо снятых с производства позиций;
- Оперативные сроки поставки под заказ (от 5 рабочих дней);
- Экспресс доставка в любую точку России;
- Помощь Конструкторского Отдела и консультации квалифицированных инженеров;
- Техническая поддержка проекта, помощь в подборе аналогов, поставка прототипов;
- Поставка электронных компонентов под контролем ВП;
- Система менеджмента качества сертифицирована по Международному стандарту ISO 9001;
- При необходимости вся продукция военного и аэрокосмического назначения проходит испытания и сертификацию в лаборатории (по согласованию с заказчиком);
- Поставка специализированных компонентов военного и аэрокосмического уровня качества (Xilinx, Altera, Analog Devices, Intersil, Interpoint, Microsemi, Actel, Aeroflex, Peregrine, VPT, Syfer, Eurofarad, Texas Instruments, MS Kennedy, Miteq, Cobham, E2V, MA-COM, Hittite, Mini-Circuits, General Dynamics и др.);

Компания «Океан Электроники» является официальным дистрибьютором и эксклюзивным представителем в России одного из крупнейших производителей разъемов военного и аэрокосмического назначения «JONHON», а так же официальным дистрибьютором и эксклюзивным представителем в России производителя высокотехнологичных и надежных решений для передачи СВЧ сигналов «FORSTAR».

## JONHON

«JONHON» (основан в 1970 г.)

Разъемы специального, военного и аэрокосмического назначения:

(Применяются в военной, авиационной, аэрокосмической, морской, железнодорожной, горно- и нефтедобывающей отраслях промышленности)

«FORSTAR» (основан в 1998 г.)

ВЧ соединители, коаксиальные кабели,  
кабельные сборки и микроволновые компоненты:

(Применяются в телекоммуникациях гражданского и специального назначения, в средствах связи, РЛС, а так же военной, авиационной и аэрокосмической отраслях промышленности).
