

# TLF50251ELV50

## 2.2 MHz Step-Down Regulator 500 mA, 5 V, low quiescent current

### 1 Overview

#### Features

- 500 mA step down voltage regulator
- 5 V Output voltage
- $\pm 2\%$  output voltage tolerance
- Low quiescent current (less than 45  $\mu\text{A}$  at nominal battery voltage)
- Integrated power transistor
- Current mode PWM regulation
- PFM mode for light load current
- Input voltage range from 4.75 V to 45 V
- 2.2 MHz switching frequency
- 100% Duty cycle
- Synchronization input
- Very low shutdown current consumption ( $< 2 \mu\text{A}$ )
- Soft-start function
- Reset generator
- Input undervoltage lockout
- Suited for automotive applications:  $T_j = -40^\circ\text{C}$  to  $150^\circ\text{C}$
- Green Product (RoHS compliant)

#### Potential applications

- Applications with a 5.0 V switching regulator as replacement for linear voltage regulator with low quiescent current, such as:
  - dashboard
  - engine management
  - braking
  - body
  - infotainment

**Overview****Product validation**

Qualified for automotive applications. Product Validation according to AEC-Q100/101.

**Description**

The TLF50251EL is a high frequency PWM step-down DC/DC converter with an integrated PMOS power switch, packaged in a small PG-SSOP-14 with exposed pad. The wide input voltage range from 4.75 V to 45 V makes the TLF50251EL suitable for a wide variety of applications. The device is designed to be used under harsh automotive environmental conditions.

The switching frequency of nominal 2.2 MHz allows the use of small and cost-effective inductors and capacitors, resulting in a low, predictable output voltage ripple and in minimized consumption of board space.

In light load condition the device operates in Pulse Frequency Modulation (PFM) to optimize the efficiency. Between the single pulses, all internal controlling circuitry is switched off to reduce the internal power consumption.

The TLF50251EL includes protection features such as a cycle-by-cycle current limitation, overtemperature shutdown and input undervoltage lockout. The enable function, in shutdown mode with less than 2  $\mu$ A current consumption, enables easy power management in battery-powered systems.

The voltage regulation loop provides an excellent line and load regulation, the stability of the loop is ensured by an internal compensation network. This compensation network combined with a current mode regulation control guarantees a highly effective line transient rejection. During start-up the integrated soft-start limits the inrush current peak and prevents output voltage overshoot.

## Pin configuration

### 3 Pin configuration

#### 3.1 Pin assignment

Figure 2 Pin configuration

#### 3.2 Pin definitions and functions

Pin	Symbol	Function
1	RO	<b>Reset Output</b> Provides the reset output signal. Open collector output, connect a pull up resistor to $V_{CC}$ or another voltage source, if feature is used, if not, leave open.
2	N.C.	<b>Not Connected</b> Internally not connected. Leave open or connect to GND.
3	N.C.	<b>Not Connected</b> Internally not connected. Leave open or connect to GND.
4	SYNC	<b>Synchronization input</b> Connect to an external clock signal in order to synchronize/adjust the switching frequency. This feature is not functionally in PFM mode.
5	FREQ	<b>Frequency adjustment pin</b> Connect an external resistor to GND to adjust the switching frequency, do not leave open. In case the synchronization option is used, the resistor must be dimensioned close to the desired synchronization frequency.
6	RTADJ	<b>Reset Threshold Adjust pin</b> Connect an external resistor divider to adjust the Reset threshold. If function is not used, connect to $V_{CC}$ .
7	FB	<b>Feedback input</b> Connect this pin directly to the output capacitor. Also input for internal power supply. The internal power supply is taken from the output voltage.

### Pin configuration

Pin	Symbol	Function
8	N.C.	<b>Not Connected</b> Internally not connected. Leave open or connect to GND.
9	GND	<b>Ground</b> Connect this pin directly with low inductive and broad trace to ground, do not leave open.
10	GND	<b>Ground</b> Connect this pin directly with low inductive and broad trace to ground, do not leave open.
11	SWO	<b>Buck Switch Output</b> Drain of the integrated power-PMOS transistor. Connect directly to the cathode of the catch diode and the buck circuit inductance.
12	N.C.	<b>Not Connected</b> Internally not connected. Leave open or connect to GND.
13	VS	<b>Supply Voltage input</b> Connect to supply voltage source.
14	EN	<b>Enable input</b> Switch to high level to enable the device, switch to low level to disable the device.
Exposed pad		Connect to heatsink area and GND by low inductance wiring.

## General product characteristics

1) Not subject to production test, specified by design

2) ESD susceptibility HBM according to ANSI/ESDA/JEDEC JS-001.

3) ESD susceptibility, Charged Device Model "CDM" EIA/JESD22-C101 or ESDA STM5.3.1

### Notes

1. Stresses above the ones listed here may cause permanent damage to the device. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.
2. Integrated protection functions are designed to prevent IC destruction under fault conditions described in the data sheet. Fault conditions are considered as "outside" normal operating range. Protection functions are not designed for continuous repetitive operation.

## General product characteristics

## 4.2 Functional range

Table 2 Functional range

Parameter	Symbol	Values			Unit	Note or Test Condition	Number
		Min.	Typ.	Max.			
Supply voltage	$V_S$	4.75	–	45	V	–	P_4.2.1
Buck inductor	$L_{BU}$	3.3	–	22	$\mu\text{H}$	–	P_4.2.2
Buck capacitor	$C_{BU1}$	10	–	50	$\mu\text{F}$	–	P_4.2.3
Buck capacitor ESR	$ESR_{BU1}$	0.015	–	0.100	$\Omega$	– <sup>1)</sup>	P_4.2.4
Junction temperature	$T_j$	-40	–	150	$^{\circ}\text{C}$	–	P_4.2.5

1) See section **“Application information”** on Page 25 for loop compensation requirements and refer to Application Note for dimensioning the output filter.

*Note:* Within the functional range the IC operates as described in the circuit description. The electrical characteristics are specified within the conditions given in the related electrical characteristics table.

## 4.3 Thermal resistance

Table 3 Thermal resistance

Parameter	Symbol	Values			Unit	Note or Test Condition	Number
		Min.	Typ.	Max.			
Junction to case <sup>1)</sup>	$R_{thJC}$	–	10	–	K/W	–	P_4.3.1
Junction to ambient <sup>2)</sup>	$R_{thJA}$	–	47	–	K/W	2s2p	P_4.3.2
	$R_{thJA}$	–	54	–	K/W	1s0p + 600 mm <sup>2</sup>	P_4.3.3
	$R_{thJA}$	–	64	–	K/W	1s0p + 300 mm <sup>2</sup>	P_4.3.4

1) Not subject to production test, specified by design.

2) Specified  $R_{thJA}$  value is according to JEDEC 2s2p (JESD 51-7) + (JESD 51-5) and JEDEC 1s0p (JESD 51-3) + heatsink area at natural convection on FR4 board.

## Buck regulator

# 5 Buck regulator

## 5.1 Description

The TLF50251EL is a monolithic current mode step down converter with adjustable switching frequency  $f_{OSC}$ . It is capable to operate either in Pulse Width Modulation (PWM) or in Pulse Frequency Modulation (PFM) Mode.

### 5.1.1 Regulator loop

#### Power stage

The supply voltage is connected to pin VS. Between pin VS and pin SWO there is an internal shunt resistor and the internal PMOS power stage. The PMOS is driven by the driver stage.

#### Regulator block

The feedback signal  $V_{FB}$  is connected to pin FB. Between pin FB and pin GND is an internal resistor divider. An error amplifier and a comparator are connected to this resistor divider: The error amplifier EA-gmV, which is controlling the output voltage in PWM mode, and the PFM comparator, which will switch the TLF50281EL into PFM mode and trigger the pulses. The error amplifier EA-gmV is connected to the PWM comparator. The regulation loop operates in current mode: The output current of EA-gmV is subtracted from the sum of the current loop CS-gml and the slope compensation  $I_{SLOPE}$ . The result is evaluated by PWM Comp (a current comparator). The output of PWM Comp defines duty cycle (pulse-width-modulated signal) in PWM mode.

The Slope Compensation added to the signal from the error amplifier EA-gmV to the PWM Comparator ensures that no sub harmonics will occur on the input current.

The PWM comparator output and the PFM comparator output are connected to the PWM /PFM logic.

An external resistor at pin FREQ is required to set the switching frequency (for details please refer to chapter 8 Module Oscillator). The TLF50251EL may also be synchronized to an external frequency. In this case an external clock signal should be connected to pin SYNC. The frequency setting resistor at pin FREQ is still necessary, it has to be selected according to the desired synchronization frequency (for details please refer to [Chapter 8 Oscillator](#)).

The TLF50251EL can only be synchronized to an external frequency source in PWM mode, this function does not work in PFM mode.

The clock manager is clocking the PWM/PFM logic. The PWM/PFM logic is triggering the driver to apply pulses to the internal PMOS power stage.

#### Safety features

The shunt resistor in line with the internal PMOS power stage (between pin VS and the power stage) is connected to a current sense amplifier CS-gml. It detects the voltage above the shunt resistor. The amplifier creates a signal which shuts the pulse down in case that the shunt voltage exceeds the reference limit. The current limitation acts as a cycle-by-cycle limitation. Cycle-by-cycle limitation means, that every pulse is switched off as soon as the current through the PMOS exceeds the buck peak over current limit  $I_{BUOC}$ . The next pulse starts and will also be switched off as soon as the current limit is exceeded again. This results in a lowered output voltage whilst the output current is limited to a certain value.

Input undervoltage shutdown: If the input voltage is below the input undervoltage shutdown threshold  $V_{S,off}$  the device will shut down.

Output overvoltage protection: If the output voltage exceeds the PFM threshold the device will switch from PWM to PFM. Pulses will then be generated only depending on the value of the output voltage  $V_{CC}$ .

## Buck regulator

Soft start function: An integrated soft start function of duration  $t_{start}$  ensures, that the inrush current will be limited. After an overtemperature shutdown the regulator always restarts with a soft start.

Overtemperature shutdown: An internal temperature sensor detects the temperature of the device. It will be switched off if the junction temperature exceeds the overtemperature shutdown threshold  $T_{j,sd}$  and restart with a certain hysteresis  $T_{j,sd\_hyst}$  (for details please refer to [Chapter 7 Enable and thermal shutdown](#)).

## Biasing

The internal biasing is taken from pin VS as well as from pin FB (connected to  $V_{CC}$ ) (for details please refer to [Chapter 7 Enable and thermal shutdown](#)). Thus the power consumption from the supply voltage  $V_S$  can be minimized.

Figure 3 Block diagram buck regulator

### 5.1.2 PWM (Pulse Width Modulation) mode

Under normal conditions the TLF50251EL will operate with a constant switching frequency  $f_{OSC}$  in PWM mode. The ratio between switch-on-time  $T_{ON}$  and switch-off-time  $T_{OFF}$  is mainly determined by the ratio between the input voltage  $V_S$  and the output voltage  $V_{CC}$  and is influenced by the output current  $I_{CC}$ .

In PWM mode the device may operate with 100% duty cycle, in this case the internal PMOS is constantly conducting current. The current limitation feature is operating under this condition.

If the switch-on-time  $T_{ON}$  should theoretically be below the minimum threshold  $T_{ON,min}$  (due to low load or due to the ratio between input voltage  $V_S$  and output voltage  $V_{CC}$  depending on the switching frequency), it will be reduced to the minimum value switch-on-time  $T_{ON,min}$  and stay there. As a consequence the output voltage  $V_{CC}$  will increase. The PFM comparator detects the PFM threshold and will then switch the device into PFM mode. There is no possibility to disable the PFM function.

## Buck regulator

### 5.1.3 PFM (Pulse Frequency Modulation) mode

To optimize the efficiency and to reduce the current consumption, the TLF50251EL automatically switches to PFM mode under low load conditions. In PFM mode the internal power stage including the driver stage is switched off and will only be switched on for applying pulses to charge the output capacitor. The pulses will be created by monitoring the voltage of the output filter capacitor  $C_{OUT}$ . Thus in PFM mode the repetition time of pulses depend on the output current and/or the ratio between input voltage  $V_S$  and output voltage  $V_{CC}$ .

#### Transition from PWM to PFM

**Figure 4** shows the transition from Pulse Width Modulation to Pulse Frequency Modulation under the assumption, that the input voltage  $V_S$  will be constant and only the output current  $I_{CC}$  will vary. The diagram shows the principle, in reality the signals might look slightly different. The diagram is without scale in respect of time, voltage and current values.

Starting from left of the figure a certain output current, here named  $I_1$ , is applied to the regulator output. This results in a duty cycle  $D_1$  with the on-time  $T_{ON1}$  of the internal power stage. The switching frequency  $f_{OSC}$  is constant as set by the frequency setting resistor  $R_{FREQ}$ . The regulator is in PWM mode, the output voltage is  $V_{REF\_PWM}$  which is equal to  $V_{FB}$  in PWM mode.

At point  $t_1$  the output current decreases from  $I_1$  to a lower  $I_2$ . This results in a duty cycle  $D_2$  with the on-time  $T_{ON2}$  of the internal power stage. Due to the reduced output load the on-time  $T_{ON2}$  is shorter (the regulator is in Discontinuous Conduction Mode DCM) than  $T_{ON1}$ . The switching frequency  $f_{OSC}$  is constant as set by the frequency setting resistor  $R_{FREQ}$ . The regulator is still in PWM mode, the output voltage is  $V_{REF\_PWM}$  which is equal to  $V_{FB}$  in PWM mode. In Continuous Conduction Mode CCM the variation from  $T_{ON1}$  to  $T_{ON2}$  will be very small due to smaller conduction losses.

At point  $t_2$  the output current decreases again from  $I_2$  to a lower  $I_3$ . As a consequence the on-time  $T_{ON}$  will be reduced also. The output current  $I_3$  is so low, that the on-time  $T_{ON3}$  would be smaller than the  $T_{ON,min}$ . The regulator does not allow a on-time smaller than  $T_{ON,min}$ . Therefore we can say that the output current  $I_3$  is under the imaginary current threshold for transition from PWM to PFM  $I_{PWM/PFM}$ . With the pulse staying at on-time  $T_{ON,min}$  the output voltage  $V_{CC}$  will rise. The regulator is still in PWM mode, but the output voltage rises.

At point  $t_3$  after a normal time period  $T_{PWM}$  as adjusted by the frequency setting resistor  $R_{FREQ}$ , a further pulse of the duration  $T_{ON,min}$  is applied, the output voltage  $V_{CC}$  keeps on rising. The regulator is still in PWM mode.

At point  $t_4$  the output voltage  $V_{CC}$  touches (or exceeds) the voltage threshold for transition from PWM to PFM  $V_{PWM/PFM}$ . The regulator is now switching internally from PWM to PFM. In PFM mode the power consumption of the internal blocks is reduced. The reference for the output voltage  $V_{CC}$  is switched from  $V_{REF\_PWM}$  (which is equal to  $V_{FB}$  in PWM mode) to  $V_{REF\_PFM}$  (which is equal to  $V_{FB}$  in PFM mode). The reference for  $V_{FB}$  in PFM mode is higher than the reference in PWM mode to avoid voltage dumps at the output voltage  $V_{CC}$  due to sudden load steps and to give the regulator more reaction time to switch back to PWM mode.

The regulator is now in PFM mode, the output voltage is  $V_{REF\_PFM}$  which is equal to  $V_{FB}$  (or slightly higher) in PFM mode.

The output voltage  $V_{CC}$  is monitored and as soon as it touches the PFM reference voltage  $V_{REF\_PFM}$  a pulse of the on-time  $T_{ON,min}$  is triggered. The time between two pulses is depending on the discharging of the output capacitor  $C_{OUT}$ .

## Buck regulator

**Figure 4** PWM to PFM transition (timing diagram)

### Transition from PFM to PWM

**Figure 5** shows the transition from Pulse Frequency Modulation to Pulse Width Modulation under the assumption, that the input voltage  $V_S$  will be constant, and only the output current  $I_{CC}$  will vary. The diagram shows the principle, in reality the signals might look slightly different. The diagram is without scale in respect of time, voltage and current values.

Starting from left of the figure a certain output current, here named  $i_3$ , is applied to the regulator output.  $i_3$  shall be below the imaginary current threshold for transition from PFM to PWM  $i_{PFM/PWM}$ . The regulator is in PFM mode, the output voltage is  $V_{REF\_PFM}$ , which is equal to  $V_{FB}$  in PFM mode (or slightly higher).

Pulses of the duration  $T_{ON,min}$  are triggered whenever the output voltage  $V_{CC}$  touches the PFM reference voltage  $V_{REF\_PFM}$ .

At point  $t_5$  the output current increases from  $i_3$  to a higher  $i_2$ , that shall be above the imaginary current threshold for transition from PFM to PWM  $i_{PFM/PWM}$ . Due to the higher output current more pulses of the duration  $T_{ON,min}$  have to be triggered, the frequency of these pulses is monitored. The frequency of these pulses increases until it is higher than the switching frequency  $f_{OSC}$  set by the frequency setting resistor  $R_{FREQ}$ . The regulator is still in PFM mode.

At point  $t_6$  the frequency monitoring detects that the frequency of the PFM pulses is being higher than the frequency threshold for transition from PFM to PWM  $f_{PFM/PWM}$ . Therefore the regulator switches back to PWM mode. This results in a certain duty cycle  $D_2$  with the on-time  $T_{ON2}$  of the internal power stage. The time period  $T_{PWM}$  is as adjusted by the frequency setting resistor  $R_{FREQ}$ .

Buck regulator

Figure 5 PFM to PWM transition (timing diagram)

Frequency variation during PWM/PFM transition

Figure 6 shows the transition from Pulse Frequency Modulation to Pulse Width Modulation (and vice versa) in relation to output current and switching frequency. The diagram shows the principle, in reality the signals might be slightly different. The diagram is without scale in respect of frequency and current values.

The transition from PWM to PFM is shown in a grey line. Starting from right the switching frequency  $f_{PWM}$  is constant as set by the frequency setting resistor  $R_{FREQ}$ . The output current  $I_{CC}$  is decreasing.

As soon as the output current  $I_{CC}$  is below the imaginary current threshold for transition from PWM to PFM  $I_{PWM/PFM}$ , the regulator will be switched from PWM to PFM mode depending on the output voltage  $V_{CC}$ . With the output current  $I_{CC}$  decreasing, the switching frequency will also decrease, as the pulses are triggered by monitoring the output voltage  $V_{CC}$  at capacitor  $C_{OUT}$ .

The transition from PFM to PWM is shown in a black line. Starting from left the switching frequency is increasing with the increasing output current  $I_{CC}$ .

As soon as the switching frequency is crossing the frequency threshold for transition from PFM to PWM  $f_{PFM/PWM}$  (which is above the switching frequency  $f_{OSC}$  set by the frequency setting resistor  $R_{FREQ}$ ) the regulator will switch from PFM to PWM.

Buck regulator

## Reset

## 6 Reset

### 6.1 Description reset function

#### Principle:

The reset function supervises the value of the regulator output voltage  $V_{CC}$ . The result is monitored by the status of pin RO. A high level at pin RO means that the output voltage  $V_{CC}$  is above the desired reset threshold. A low level at pin RO means that the output voltage  $V_{CC}$  is below the desired reset threshold. The reset function does not work, if the supply ( $V_{FB}$ ) voltage is below 1 V.

#### Adjustment of reset threshold:

The reset generator consists of an internal comparator with a reset threshold  $V_{RO,T}$ . By adding an external resistor divider between the output voltage  $V_{CC}$  and ground (GND) and connecting the point between the upper (R1) and lower (R2) resistor to pin RTADJ the desired reset threshold  $V_{RT}$  (where the reset generator indicates an undervoltage) might be adjusted.

If reset function is not used please connect pin RTADJ to  $V_{CC}$ .

(6.1)

$$\text{Desired reset threshold} = V_{RO,T} \left( \frac{R1 + R2}{R2} \right) = V_{RT}$$

#### Operation mode (please refer to [Figure 7](#)):

The reset generator starts operating as soon as the regulator is activated by supplying the device with an input (battery) voltage higher than the input voltage startup threshold  $V_{S,ON}$  and a valid high signal  $V_{EN,hi}$  at pin EN.

The pin RO is low at this time.

When the regulator starts to operate,  $V_{CC}$  ramps up and passes the desired reset threshold. The reset delay time  $t_{RD}$  is the time duration between that point and pin RO turning to high level.

The reset reaction time  $t_{RR}$  is the maximum duration or time, the output voltage  $V_{CC}$  may dip below the desired reset threshold, before a reset is indicated and pin RO is pulled to low level. This is implemented to avoid wrong reset triggering by short glitches on the output voltage  $V_{CC}$ . If the output voltage  $V_{CC}$  dips below the desired reset threshold  $V_{RT}$  for more than  $t_{RR}$ ;  $t_{RR}$  is also the time until pin RO is pulled below  $V_{RO,L}$ .

A voltage dip at the output voltage  $V_{CC}$  leads to a low level at pin RO under the following condition:

(6.2)

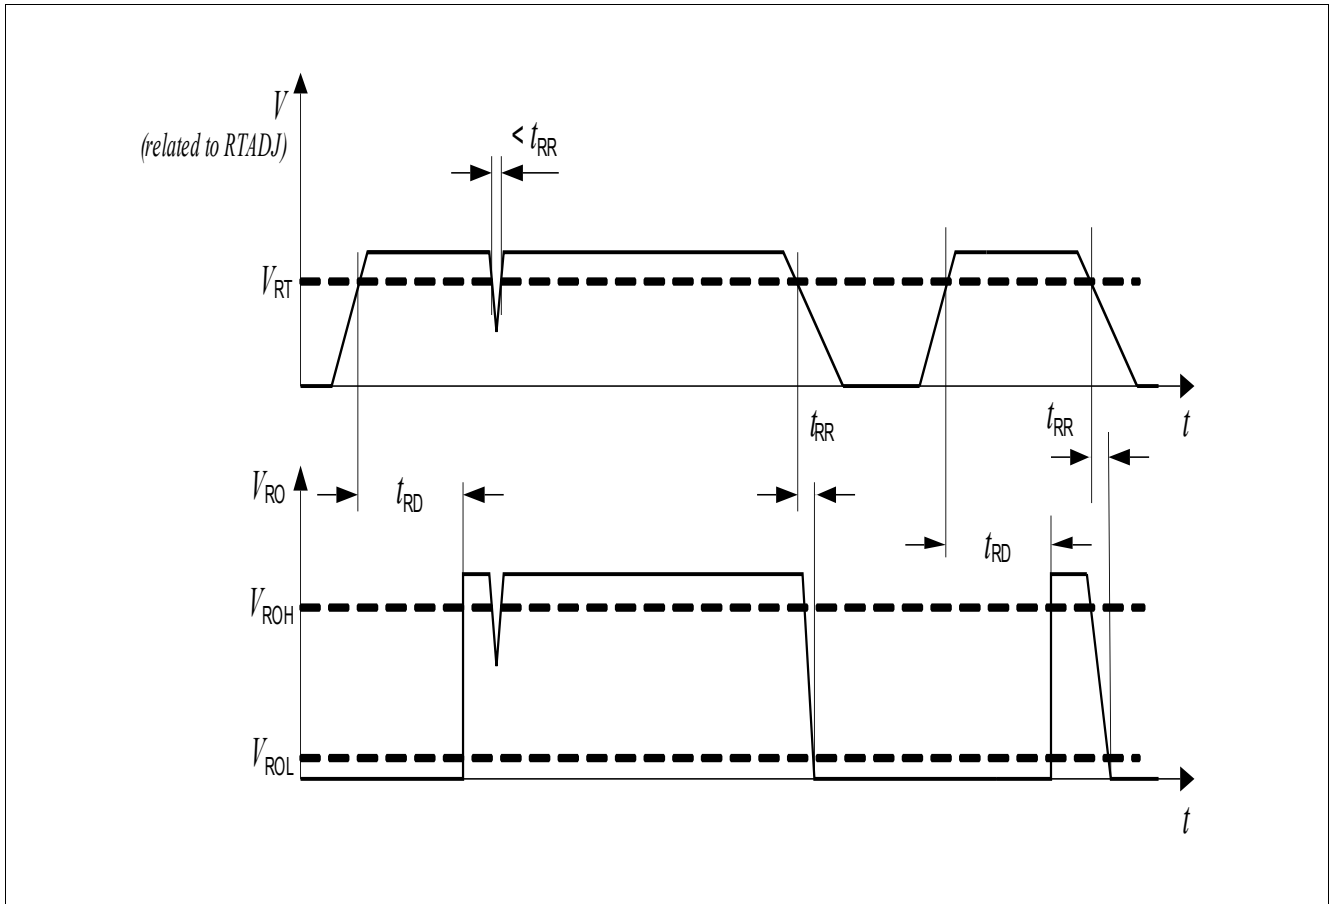

$$V_{CC} < V_{RO,T} \left( \frac{R1 + R2}{R2} \right) \text{ (for } t > t_{RR} \text{)}$$

In case the pin RO is pulled to low level, it stays low for the time until the output voltage  $V_{CC}$  is higher than the desired reset threshold  $V_{RT}$  plus the reset delay time  $t_{RD}$ .

## Reset

### Reset output pin (please refer to [Figure 7](#)):

The reset output is an open collector structure. As soon as a reset condition occurs, the pin is pulled to ground. A pull up resistor (R4) connected to  $V_{CC}$  or another voltage source is necessary. If the supply ( $V_{FB}$ ) voltage is below 1 V the open collector structure does no longer pull pin RO to ground. In this case pin RO goes up to the pull-up voltage (if not supplied by voltage  $V_{CC}$ ).

**Figure 7** Reset function and timing diagram

- ROH:= Reset Output High Level, depending on voltage sourcing the pull-up resistor at pin RO.
- ROL:= Reset Output Low Level, Reset signal valid.

The recommended maximum value for the sum of both resistors R1 and R2 of the external resistor divider is 1.2 M $\Omega$ .

## Reset

## 6.2 Electrical characteristics reset function

Table 5 Electrical characteristics: reset

$V_S = 6.0\text{ V to }40\text{ V}$ ,  $T_j = -40^\circ\text{C to }150^\circ\text{C}$ , all voltages with respect to ground (unless otherwise specified)

Parameter	Symbol	Values			Unit	Note or Test Condition	Number
		Min.	Typ.	Max.			
<b>Reset Output RO</b>							
Output voltage low	$V_{RO,L}$	–	0.2	0.4	V	$V_{CC} \geq 1\text{ V}$ ; $V_{RTADJ} < 0.9\text{ V}$ , $I_{RO} = 1\text{ mA}$	P_6.2.1
Sink current limit	$I_{R,S,MAX}$	1	–	–	mA	$V_{CC} = 5\text{ V}$ ; $V_{RTADJ} < 0.9\text{ V}$ , $V_{RO} = 0.4\text{ V}$	P_6.2.2
Leakage current	$I_{RO,L,MAX}$	–	–	1	$\mu\text{A}$	$V_{RO} = 5\text{ V}$	P_6.2.3

Output undervoltage hysteresis	$V_{RO,T,Hyst}$	50	–	150	mV	Output voltage decreasing	P_6.2.5
Pin RTADJ input current	$I_{RTADJ,MAX}$	-1	0.1	1	$\mu\text{A}$	$V_{RTADJ} = 1.2\text{ V}$	P_6.2.6
Delay time	$t_{RD}$	6	8	10	ms	–	P_6.2.7
Reset reaction time	$t_{RR}$	2	–	10	$\mu\text{s}$	Output voltage decreasing	P_6.2.8

## Enable and thermal shutdown

# 7 Enable and thermal shutdown

## 7.1 Description

A valid high level at pin EN ( $V_{EN,hi}$ ) turns the regulator on, a valid low level at pin EN ( $V_{EN,lo}$ ) turns the regulator off. In off state the current consumption of the device is less than 2  $\mu$ A. An integrated pull down resistor at pin EN ( $R_{EN,INT}$ ) ensures, that the device is switched off, if pin EN is left open.

The integrated thermal shutdown function turns off the power switch in case of overtemperature. The typical junction shutdown temperature is 175°C, with a min. of 155°C. After cooling down, the IC will automatically restart with a soft start into normal operation. The thermal shutdown is an integrated protection function designed to prevent IC destruction when operating under fault conditions. It should not be used for normal operation.

## 7.2 Electrical characteristics Enable, bias and thermal shutdown

**Table 6 Electrical characteristics: Enable, bias and thermal shutdown**

$V_S = 6.0$  V to 40 V,  $T_j = -40^\circ$ C to 150°C, all voltages with respect to ground (unless otherwise specified)

Parameter	Symbol	Values			Unit	Note or Test Condition	Number
		Min.	Typ.	Max.			
<b>Enable EN</b>							
Current consumption, shut down mode	$I_{q,OFF}$	–	0.1	2	$\mu$ A	$V_{EN} = 0$ V; $T_j < 105^\circ$ C; $V_S = 16$ V	P_7.2.1
Current consumption of $V_{CC}$	$I_{q,ON,V_{CC}}$	–	–	60	$\mu$ A	$V_{EN} = 5.0$ V; $V_S = 16$ V; $V_{CC} = 5.4$ V; $T_j < 105^\circ$ C; PFM mode	P_7.2.2

Enable high signal valid	$V_{EN,hi}$	3.0	–	–	V	–	P_7.2.4
Enable low signal valid	$V_{EN,lo}$	–	–	0.8	V	–	P_7.2.5
Enable hysteresis	$V_{EN,HY}$	50	200	400	mV	–	P_7.2.6
Enable high input current	$I_{EN,hi}$	–	–	3	$\mu$ A	$V_{EN} = 16$ V	P_7.2.7
Enable low input current	$I_{EN,lo}$	–	0.1	1	$\mu$ A	$V_{EN} = 0.5$ V	P_7.2.8
Enable internal resistor to GND	$R_{EN,INT}$	7	12	20	M $\Omega$	$V_{EN} = 3$ V	P_7.2.9
<b>Internal overtemperature protection</b>							
Overtemperature shutdown	$T_{j,sd}$	155	175	195	$^\circ$ C	1)	P_7.2.14
Overtemperature shutdown hysteresis	$T_{j,sd,hyst}$	–	15	–	K		P_7.2.15

1) Specified by design. Not subject to production test.

## Oscillator

## 8 Oscillator

### 8.1 Description

The oscillator supplies the device with a constant frequency. The power switch will be switched on and off with a constant frequency  $f_{\text{OSC}}$ . The time period  $T_{\text{PWM}}$  is derived from this frequency and some safety functions are synchronized to this frequency.

The oscillator frequency can be set by connecting an external resistor  $R_{\text{FREQ}}$  between pin FREQ and GND using the following table (selected values, for more precise setting please refer to [Figure 8](#)).

#### Frequency setting resistor

Frequency adjusting resistor	$R_{\text{FREQ}}$	39	43	56	82	100	k $\Omega$	P_8.1.1
Oscillator frequency	$f_{\text{OSC}}$	2400	2250	1800	1330	1100	kHz	P_8.1.2

**Figure 8** Switching frequency  $f_{\text{OSC}}$  versus frequency setting resistor  $R_{\text{FREQ}}$ .

The turn-on frequency can optionally be set externally via the SYNC pin. In this case the synchronization of the PWM-on signal refers to the falling edge of the SYNC-pin input signal. In case the synchronization to an external clock signal is not needed, the SYNC pin should be connected to ground. The frequency setting resistor  $R_{\text{FREQ}}$  is also necessary for SYNC option and must be dimensioned according to the desired synchronization frequency (the ratio between synchronization and internal frequency has to be less than or equal to 1).

The synchronization function is not available in PFM mode.

## Oscillator

## 8.2 Electrical characteristics buck regulator

Table 7 Electrical characteristics: buck regulator

$V_S = 6.0\text{ V to }40\text{ V}$ ,  $T_j = -40^\circ\text{C to }150^\circ\text{C}$ , all voltages with respect to ground (unless otherwise specified)

## Application information

### 9.1 General layout recommendations

#### Introduction:

A switch mode step down converter is a potential source of electromagnetic disturbances which may affect the environment as well as the device itself and cause sporadic malfunction up to damages depending on the amount of noise.

In principal we may consider the following basic effects:

- radiated magnetic fields caused by circular currents, occurring mostly with the switching frequency and their harmonics;
- radiated electric fields, often caused by (voltage) oscillations;
- conducted disturbances (voltage spikes or oscillations) on the lines, mostly input and output lines.

#### Radiated magnetic fields:

Radiated magnetic fields are caused by circular currents occurring in so called “current windows”. These circular currents are alternating currents which are driven by the switching transistor. The alternating current in these windows are driving magnetic fields. The amount of magnetic emissions is mainly depending on the amplitude of the alternating current and the size of the so-called “window” (this is the area, which is defined by the circular current paths.

We can divide into two windows:

- the input current “window” (path consisting of  $C_{IN2}$ ,  $C_{IN3}$ ,  $L_{OUT}$  and  $C_{OUT}$ ): Only the alternate content of the input current  $I_S$  is considered;
- the output current “window” (path consisting of  $D_{CATCH}$ ,  $L_{OUT}$  and  $C_{OUT}$ ): Output current ripple  $\Delta I$ .

The area of these “windows” has to be kept as small as possible, with the relating elements placed next to each others as close as possible. It is highly recommended to use a ground plane as a single layer which covers the complete regulator area with all components shown in the application diagram. All connections to ground shall be as short as possible.

#### Radiated electric fields:

Radiated electric fields are caused by voltage oscillations occurring by stray inductances and stray capacitances at the connection between internal power stage (pin SWO), freewheeling diode  $D_{CATCH}$ , and output capacitor  $C_{OUT}$ . They are also of course influenced by the commutation of the current from the internal power stage to the freewheeling diode  $D_{CATCH}$ . Their frequencies might be above 100 MHz. Therefore, it is recommended to use a fast Schottky diode and to keep the connections in this area as low inductive as possible. This can be achieved by using short and broad connections and by arranging the related parts as close as possible. Following the recommendation of using a ground layer these low inductive connections will form together with the ground layer small capacitances which are desirable to damp the slope of these oscillations. The oscillations use connections or wires as antennas, this effect can also be minimized by the short and broad connections.

#### Conducted disturbances:

Conducted disturbances are voltage spikes or voltage oscillations, occurring permanently or by occasion mostly on the input or output connections. Comparable to the radiated electric fields they are caused by voltage stage, freewheeling diode  $D_{CATCH}$ , and output capacitor  $C_{OUT}$ .

Their frequencies might be above 100 MHz. They are super positioned to the input and output voltage and might therefore disturb other components of the application.

The countermeasures against conducted disturbances are similar to the radiated electric fields:

**Application information**

- it is recommended to use short and thick connections between the single parts of the converter;
- all parts shall be mounted close together;
- additional filter capacitors (ceramic, with low ESR i.e.  $C_{IN3}$  in the application diagram) in parallel to the output and input capacitor and as close as possible to the switching parts. Input and load current must be forced to pass these devices, do not connect them via thin lines. Recommended values from 10 nF to 220 nF;
- for the input filter a so called  $\pi$  – Filter for maximum suppression might be necessary, which requires additional capacitors on the input.

**9.2 Further application information**

- Please contact us for information regarding the FMEA pin
- Existing Application Notes with more detailed information about the possibilities of this device

## WARNINGS

Due to technical requirements products may contain dangerous substances. For information on the types in question please contact your nearest Infineon Technologies office.

Except as otherwise explicitly approved by Infineon Technologies in a written document signed by authorized representatives of Infineon Technologies, Infineon Technologies' products may not be used in any applications where a failure of the product or any consequences of the use thereof can reasonably be expected to result in personal injury.

Компания «Океан Электроники» предлагает заключение долгосрочных отношений при поставках импортных электронных компонентов на взаимовыгодных условиях!

Наши преимущества:

- Поставка оригинальных импортных электронных компонентов напрямую с производств Америки, Европы и Азии, а так же с крупнейших складов мира;
- Широкая линейка поставок активных и пассивных импортных электронных компонентов (более 30 млн. наименований);
- Поставка сложных, дефицитных, либо снятых с производства позиций;
- Оперативные сроки поставки под заказ (от 5 рабочих дней);
- Экспресс доставка в любую точку России;
- Помощь Конструкторского Отдела и консультации квалифицированных инженеров;
- Техническая поддержка проекта, помощь в подборе аналогов, поставка прототипов;
- Поставка электронных компонентов под контролем ВП;
- Система менеджмента качества сертифицирована по Международному стандарту ISO 9001;
- При необходимости вся продукция военного и аэрокосмического назначения проходит испытания и сертификацию в лаборатории (по согласованию с заказчиком);
- Поставка специализированных компонентов военного и аэрокосмического уровня качества (Xilinx, Altera, Analog Devices, Intersil, Interpoint, Microsemi, Actel, Aeroflex, Peregrine, VPT, Syfer, Eurofarad, Texas Instruments, MS Kennedy, Miteq, Cobham, E2V, MA-COM, Hittite, Mini-Circuits, General Dynamics и др.);

Компания «Океан Электроники» является официальным дистрибьютором и эксклюзивным представителем в России одного из крупнейших производителей разъемов военного и аэрокосмического назначения «JONHON», а так же официальным дистрибьютором и эксклюзивным представителем в России производителя высокотехнологичных и надежных решений для передачи СВЧ сигналов «FORSTAR».

## JONHON

«JONHON» (основан в 1970 г.)

Разъемы специального, военного и аэрокосмического назначения:

(Применяются в военной, авиационной, аэрокосмической, морской, железнодорожной, горно- и нефтедобывающей отраслях промышленности)

«FORSTAR» (основан в 1998 г.)

ВЧ соединители, коаксиальные кабели, кабельные сборки и микроволновые компоненты:

(Применяются в телекоммуникациях гражданского и специального назначения, в средствах связи, РЛС, а так же военной, авиационной и аэрокосмической отраслях промышленности).
