

## Dual Adjustable Lowpass Filter

## FEATURES

- **Guaranteed Phase and Gain Matching Specs**
- **Programmable BW Up to 2.5MHz**
- **Programmable Gain (0dB/6dB/12dB/24dB)**
- **9th Order Linear Phase Response**
- Differential, Rail-to-Rail Inputs and Outputs
- Low Noise:  $-145\text{dBm/Hz}$  (Input Referred)
- Low Distortion:  $-75\text{dBc}$  at 200kHz
- Simple Pin Programming or SPI Interface
- Set the Max Speed/Power with an External R
- Operates from 2.7V to 3.6V
- Input Range from 0V to 5.5V
- 4mm × 4mm QFN Package

## APPLICATIONS

- Small/Low Cost Basestations:  
IDEN, PHS, TD-SCDMA, CDMA2000, WCDMA,  
UMTS
- Low Cost Repeaters, Radio Links, and Modems
- 802.11x Receivers
- JTRS

## DESCRIPTION

The LTC®6603 is a dual, matched, programmable lowpass filter for communications receivers and transmitters. The selectivity of the LTC6603, combined with its linear phase, phase matching and dynamic range, make it suitable for filtering in many communications systems. With 1.5° phase matching between channels, the LTC6603 can be used in applications requiring pairs of matched filters, such as transceiver I and Q channels. Furthermore, the differential inputs and outputs provide a simple interface for most communications systems.

The sampled data filter does not require an external clock yet its cutoff frequency can be set with a single external resistor with an accuracy of 3.5% or better. The external resistor programs an internal oscillator whose frequency is divided prior to being applied to the filter networks. This allows up to three cutoff frequencies that can be obtained for each external resistor value, allowing the cutoff frequency to be programmed over a range of more than six octaves. Alternatively, the cutoff frequency can be set with an external clock. The filter gain can also be programmed to 1, 2, 4 or 16.

The LTC6603 features a low power shutdown mode that can be programmed through the serial interface and is available in a 24-pin 4mm × 4mm QFN package.

## TYPICAL APPLICATION

## 2.5MHz I and Q Lowpass Filter and Dual ADC

## ABSOLUTE MAXIMUM RATINGS

(Note 1)

$V_{+IN}$ to GND .....	6V
$V_{+A}$ , $V_{+D}$ to GND .....	4V
$V_{+A}$ to $V_{+D}$ .....	-0.3V to +0.3V
Filter Inputs to GND .....	-0.3V to $V_{+IN}$ + 0.3V
Pins 3, 4 to GND .....	-0.3V to $V_{+A}$ + 0.3V
Pins 5, 6, 9-11, 15, 17, 21, 22 to GND .....	-0.3V to $V_{+D}$ + 0.3V
Output Short-Circuit Duration .....	Indefinite
Operating Temperature Range (Note 2)	
LTC6603CUF .....	-40°C TO 85°C
LTC6603IUF .....	-40°C TO 85°C
Specified Temperature Range (Note 3)	
LTC6603CUF .....	0°C TO 70°C
LTC6603IUF .....	-40°C TO 85°C
Storage Temperature Range .....	-65°C to 150°C

## PIN CONFIGURATION

## ORDER INFORMATION

## ELECTRICAL CHARACTERISTICS

**Note 1:** Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

**Note 2:** LTC6603C and LTC6603I are guaranteed functional over the operating temperature range of  $-40^{\circ}\text{C}$  to  $85^{\circ}\text{C}$ .

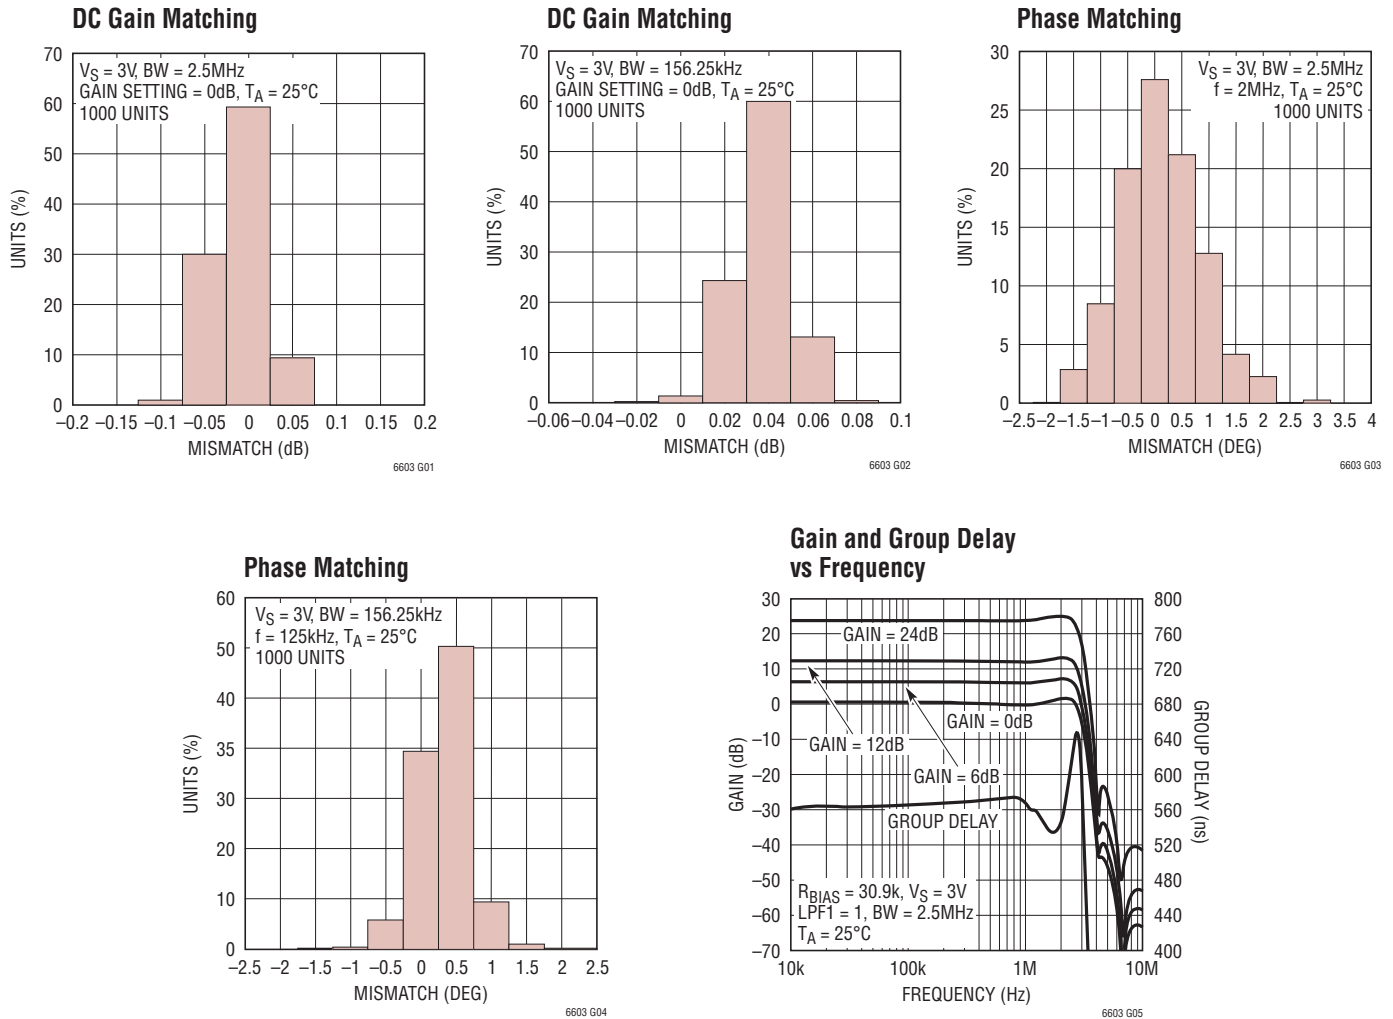

**Note 3:** LTC6603C is guaranteed to meet specified performance from  $0^{\circ}\text{C}$  to  $70^{\circ}\text{C}$ . The LTC6603C is designed, characterized and expected to meet specified performance from  $-40^{\circ}\text{C}$  to  $85^{\circ}\text{C}$  but is not tested or QA sampled at these temperatures. The LTC6603I is guaranteed to meet the specified performance limits from  $-40^{\circ}\text{C}$  to  $85^{\circ}\text{C}$ .

**Note 4:** This test measures the internal oscillator accuracy (deviation from the  $f_{\text{CLK}}$  equation). Variations in the internal oscillator cause variations in the filter cutoff frequency. See the “Applications Information” section.

**Note 5:** Guaranteed by design, not subject to test.

**Note 6:** To conform to the logic IC standard, current out of a pin is arbitrarily given a negative value.

## TYPICAL PERFORMANCE CHARACTERISTICS

## PIN FUNCTIONS

**V<sub>IN</sub> (Pin 1):** Input Voltage Supply ( $2.7V \leq V \leq 5.5V$ ). This supply must be kept free from noise and ripple. It should be bypassed directly to a ground plane with a 0.1µF capacitor unless it is tied to V<sub>+</sub>A (Pin 2). The bypass should be as close as possible to the IC, but is not as critical as the bypassing of V<sub>+</sub>A and V<sub>+</sub>D (Pin16).

**V<sub>+</sub>A (Pin 2):** Analog Voltage Supply ( $2.7V \leq V \leq 3.6V$ ). This supply must be kept free from noise and ripple. It should be bypassed directly to a ground plane with a 0.1µF capacitor. The bypass should be as close as possible to the IC.

**V<sub>OCM</sub> (Pin 3):** Output Common Mode Voltage Reference. If floated, an internal resistive divider sets the voltage on this pin to half the supply voltage (typically 1.5V), maximizing the dynamic range of the filter. If this pin is floated, it must be bypassed with a quality 1µF capacitor to ground. This pin has a typical input impedance of 3.4k and may be overdriven. Driving this pin to a voltage other than the default value will reduce the signal range the filter can handle before clipping.

**R<sub>BIAS</sub> (Pin 4):** Oscillator Frequency-Setting Resistor Input. The value of the resistor connected between this pin and ground determines the frequency of the master oscillator, and sets the bias currents for the filter networks. The voltage on this pin is held by the LTC6603 to approximately 1.17V.

For best performance, use a precision metal film resistor with a value between 30.9k and 200k and limit the capacitance on this pin to less than 10pF. This resistor is necessary even if an external clock is used.

**CLKCNTL (Pin 5):** Clock Control Input. This three-state input selects the function of CLKIO (Pin 15). Tying the CLKCNTL pin to ground allows the CLKIO pin to be driven by an external clock (CLKIO is the master clock input). If the CLKCNTL pin is floated, the internal oscillator is enabled, but the master clock is not present at the CLKIO pin (CLKIO is a no-connect). If the CLKCNTL pin is tied to V<sub>+</sub>D (Pin 16), the internal oscillator is enabled and the master clock is present at the CLKIO pin (CLKIO is the master clock output). To detect a floating CLKCNTL pin, the LTC6603 attempts to pull the pin toward mid-supply. This is realized with two internal 15µA current sources, one tied to V<sub>+</sub>D and CLKCNTL and the other one tied to ground and CLKCNTL. Therefore, driving the CLKCNTL pin high requires sourcing approximately 15µA. Likewise, driving the CLKCNTL pin low requires sinking 15µA. When the CLKCNTL pin is floated, it should be bypassed by a 1nF capacitor to ground or be surrounded by a ground shield to prevent excessive coupling from other PCB traces.

## PIN FUNCTIONS

**LPF1( $\overline{\text{CS}}$ ) (Pin 6):** TTL Level Input. When in pin programmable control mode, this pin is the MSB of the lowpass cutoff frequency control code; in serial control mode, this pin is the chip select input (active low).

**+INB, -INB (Pins 7, 8):** Channel B Differential Inputs. The input range and input resistance are described in the Applications Information section. Input voltages which exceed  $V_{+IN}$  (Pin 1) should be avoided.

**LPF0 (SCLK) (Pin 9):** TTL Level Input. When in pin programmable control mode, this pin is the LSB of the lowpass cutoff frequency control code; in serial control mode, this pin is the clock of the serial interface.

**SDI (Pin 10):** TTL Level Input. When in pin programmable control mode, this pin is left floating; in serial control mode, this pin is the serial data input.

**SDO (Pin 11):** TTL Level Input. When in pin programmable control mode, this pin is left floating; in serial control mode, this pin is the serial data output.

**-OUTB, +OUTB (Pins 12, 13):** Channel B Differential Filter Outputs. These pins can drive 1k and/or 50pF loads. For larger capacitive loads, an external 100 $\Omega$  series resistor is recommended for each output. The common mode voltage of the filter outputs is the same as the voltage at  $V_{OCM}$  (Pin 3).

**GND (Pin 14):** Ground. Should be tied to a ground plane for best performance.

**CLKIO (Pin 15):** When CLKCNTL (Pin 5) is tied to ground, CLKIO is the master clock input. When CLKCNTL is floated, CLKIO is pulled to ground by a weak pulldown. When CLKCNTL is tied to  $V_{+D}$  (Pin 16), CLKIO is the master clock output. When configured as a clock output, this pin can drive 1k and/or 5pF loads (heavier loads will cause inaccuracies).

**$V_{+D}$  (Pin 16):** Digital Voltage Supply ( $2.7V \leq V \leq 3.6V$ ). This supply must be kept free from noise and ripple. It should be bypassed directly to a ground plane with a 0.1 $\mu$ F capacitor. The bypass should be as close as possible to the IC.

**$\overline{\text{SER}}$  (Pin 17):** Interface Selection Input. When tied to  $V_{+D}$  (Pin 16) or floated, the interface is in pin programmable control mode, i.e. the filter gain and cutoff frequencies are programmed by the GAIN1, GAIN0, LPF1 and LPF0 pins. When  $\overline{\text{SER}}$  is tied to ground, the filter gain, the filter cutoff frequency and shutdown mode are programmed by the serial interface.

**-OUTA, +OUTA (Pins 18, 19):** Channel A Differential Filter Outputs. These pins can drive 1k and/or 50pF loads. For larger capacitive loads, an external 100 $\Omega$  series resistor is recommended for each output. The common mode voltage of the filter outputs is the same as the voltage at  $V_{OCM}$  (Pin 3).

**CAP (Pin 20):** Connect a 0.1 $\mu$ F bypass capacitor to this pin. Pin 20 is a buffered version of Pin 3.

**GAIN0(D0) (Pin 21):** TTL Level Input. When in pin programmable control mode, this pin is the LSB of the gain control code; in serial control mode, this pin is the LSB of the serial control register, an output.

**GAIN1 (Pin 22):** TTL Level Input. When in pin programmable control mode, this pin is the MSB of the gain control code; in serial control mode, this pin is a no-connect.

**-INA, +INA (Pins 23, 24):** Channel A Differential Inputs. The input range and input resistance are described in the Applications Information section. Input voltages which exceed  $V_{+IN}$  (Pin 1) should be avoided.

**Exposed Pad (Pin 25):** Ground. The Exposed Pad must be soldered to PCB.

## APPLICATIONS INFORMATION

### Theory of Operation (Refer to Block Diagram)

The LTC6603 features two matched filter channels, each containing gain control and lowpass filter networks that are controlled by a single control block and clocked by a single clock generator. The gain and cutoff frequency can be separately programmed. The two channels are not independent, i.e. if the gain is set to 24dB then both channels have a gain of 24dB. The filter can be clocked with an external clock source, or using the internal oscillator. A resistor connected to the  $R_{BIAS}$  pin sets the bias currents for the filter networks and the internal oscillator frequency (unless driven by an external clock). Altering the clock frequency changes the filter bandwidth. This allows the filters to be “tuned” to many different bandwidths.

### Pin Programmable Interface

As shown in Figure 1, connecting  $\overline{SER}$  to  $V_{+D}$  allows the filter to be directly controlled through the pin programmable control lines GAIN1, GAIN0, LPF1 and LPF0. The GAIN0(D0) pin is bidirectional (input in pin programmable control mode, output in serial mode). In pin programmable control mode, the voltage at GAIN0(D0) cannot exceed  $V_{+D}$ ; otherwise, large currents can be injected to  $V_{+D}$  through the parasitic diodes (see Figure 2). Connecting a 10k resistor at the GAIN0(D0) pin (see Figure 1) is recommended for current limiting, to less than 10mA.  $\overline{SER}$  has an internal

pull-up to  $V_{+D}$ . None of the logic inputs have an internal pull-up or pull-down.

### Serial Interface

Connecting  $\overline{SER}$  to ground allows the filter to be controlled through the SPI serial interface. When  $\overline{CS}$  is low, the serial data on SDI is shifted into an 8-bit shift register on the rising edge of the clock (SCLK), with the MSB transferred first (see Figure 3). Serial data on SDO is shifted out on the clock's falling edge. A high  $\overline{CS}$  will load the 8 bits of the shift register into an 8-bit D-latch, which is the serial control register. The clock is disabled internally when  $\overline{CS}$  is pulled high. Note: SCLK must be low before  $\overline{CS}$  is pulled low to avoid an extra internal clock pulse. SDO is always active in serial mode (never tri-stated) and cannot be “wire-ORed” to other SPI outputs. In addition, SDO is not forced to zero when  $\overline{CS}$  is pulled high.

An LTC6603 may be daisy-chained with other LTC6603s or other devices having serial interfaces. Daisy chaining is accomplished by connecting the SDO of the lead chip to the SDI of the next chip, while SCLK and  $\overline{CS}$  remain common to all chips in the daisy chain. The serial data is clocked to all the chips then the  $\overline{CS}$  signal is pulled high to update all of them simultaneously. Figure 4 shows an example of two LTC6603s in a daisy-chained SPI configuration.

### Self-Clocking Operation

The LTC6603 features a unique internal oscillator which sets the filter cutoff frequency using a single external resistor connected to the  $R_{BIAS}$  pin. The clock frequency is determined by the following simple formula (see Figure 5):

$$f_{CLK} = 247.2\text{MHz} \cdot 10\text{k}/R_{BIAS}$$

Note:  $R_{BIAS} \leq 200\text{k}$

The design is optimized for  $V_{+A}$ ,  $V_{+D} = 3\text{V}$ ,  $f_{CLK} = 45\text{MHz}$ , where the filter cutoff frequency error is typically <3% when a 0.1% external 54.9k resistor is used (any resistor ( $R_{BIAS}$ ) tolerance, will shift the clock frequency). With different resistor values and cutoff frequency control settings (LPF1 and LPF0), the lowpass cutoff frequency can

be accurately varied from 24.14kHz to 2.5MHz. Table 2 summarizes the cutoff frequencies that can be obtained with an external resistor ( $R_{BIAS}$ ) value of 30.9k. Note that the cutoff frequencies scale with the clock frequency. For example, if LPF1 and LPF0 are both equal to zero, and  $R_{BIAS}$  is increased from 30.9k to 200k,  $f_{CLK}$  will decrease from 80MHz to 12.36MHz and the cutoff frequency will be reduced from 156.25kHz to 24.14kHz. The cutoff frequencies that can be obtained with external resistor values of 54.9k and 200k are shown in Table 3 and Table 4, respectively. When the LTC6603 is programmed for the cutoff frequencies lower than the maximum, the power is automatically reduced. The power savings at the middle bandwidth setting (LPF1 = 0, LPF0 = 1), is about 23%, while the power savings at the lowest bandwidth setting (LPF1 = 0, LPF0 = 0) is about 60%.

**Figure 5.  $R_{BIAS}$  vs Desired Clock Frequency**

## APPLICATIONS INFORMATION

The following graphs show a few of the possible lowpass filters.

The oscillator is sensitive to transients on the positive supply. The IC should be soldered to the PCB and the PCB layout should include a 0.1μF ceramic capacitor between V<sub>+</sub>A (Pin 2) and ground, as close as possible to the IC to minimize inductance. The PCB layout should also include an additional 0.1μF ceramic capacitor between V<sub>+</sub>D (Pin 16) and ground. Avoid parasitic capacitance on R<sub>BIAS</sub> (Pin 4) and avoid routing noisy signals near R<sub>BIAS</sub>. Use a ground plane connected to Pin 14 and the Exposed Pad (Pin 25).

### Alternative Methods of Setting the Clock Frequency of the LTC6603

The oscillator may be programmed by any method that sinks a current out of the R<sub>BIAS</sub> pin. The circuit in Figure 6 sets the clock frequency by using a programmable current source and in the expression for f<sub>CLK</sub>, the resistor R<sub>BIAS</sub> is replaced by the ratio of 1.17V/I<sub>CONTROL</sub>. Because the voltage of the R<sub>BIAS</sub> pin is approximately 1.17V ±5%, the Figure 6 circuit is less accurate than if a resistor controls the clock frequency.

In this circuit, the LTC2621 (a 12-bit DAC) is daisy-chained with the LTC6603. Because the sinking current from the R<sub>BIAS</sub> pin is:

$$\frac{V_{RBIAS} \cdot k}{2^N \cdot R1}$$

the equivalent R<sub>BIAS</sub> is:

$$\frac{2^N \cdot R1}{k}$$

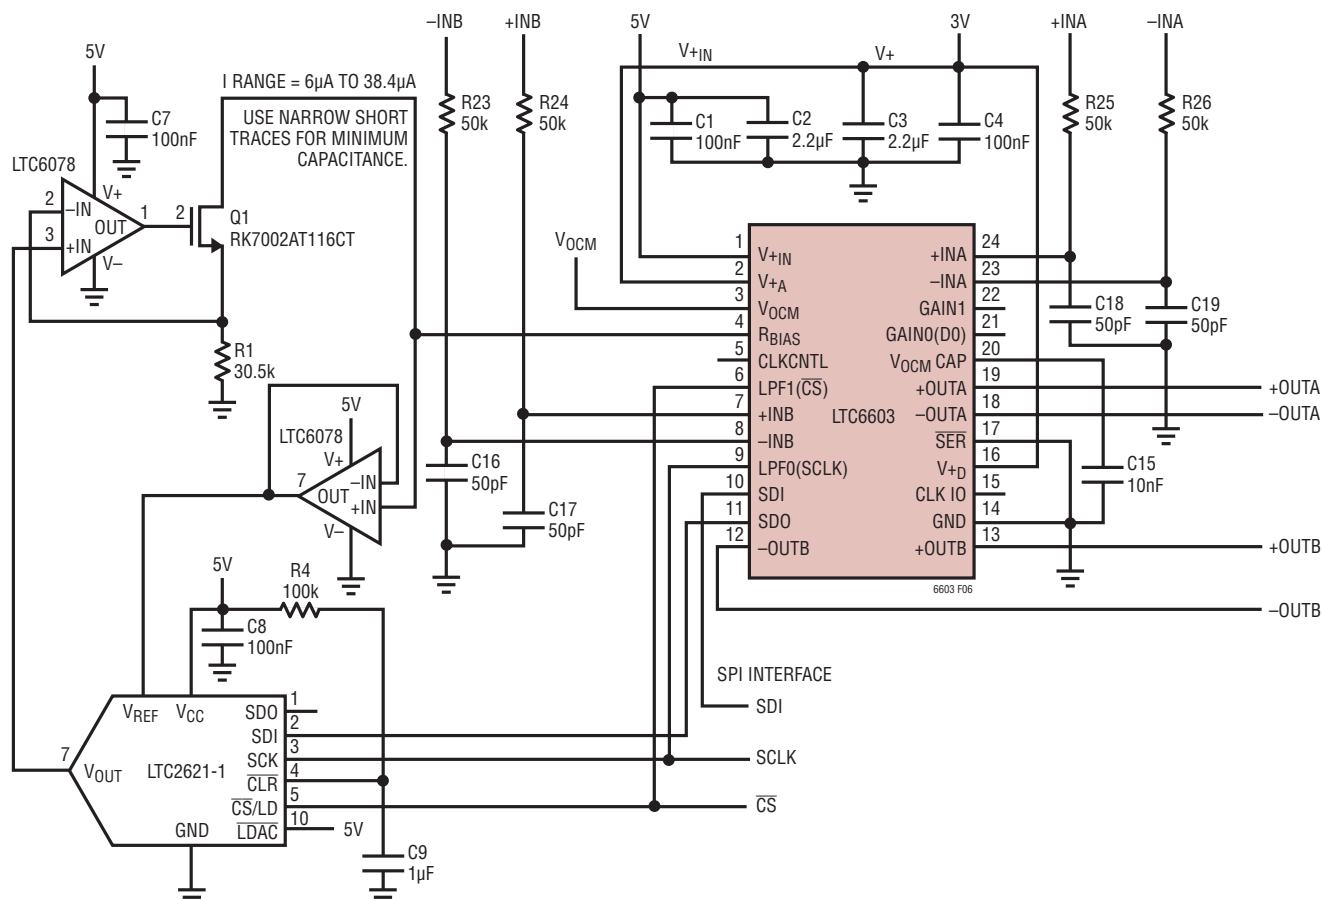

where k is the binary DAC input code and N is the resolution. Figure 7 shows some of the frequency responses that can be obtained using this circuit.

Figure 8 shows the LTC6603's oscillator configured as a VCO. A voltage source is connected in series with the R<sub>BIAS</sub> resistor. The clock frequency, f<sub>CLK</sub>, will vary with V<sub>CONTROL</sub>. Again, this circuit decouples the relationship between the current out of the R<sub>BIAS</sub> pin and the voltage of the R<sub>BIAS</sub> pin; the frequency accuracy will be degraded. The clock frequency, however, will increase monotonically with decreasing V<sub>CONTROL</sub>.

### Operation Using an External Clock

The LTC6603 may be clocked by an external oscillator for tighter bandwidth control by pulling CLKNTL (Pin 5) to ground and driving a clock into CLKIO (Pin 15). If an external clock is used, the R<sub>BIAS</sub> resistor is still necessary. The value of R<sub>BIAS</sub> must be no larger than the value that would be required for using the internal oscillator. For example, a 100k resistor would program the internal oscillator for 24.705MHz, so an external oscillator frequency of 24.705MHz would require an R<sub>BIAS</sub> resistance of no more

## APPLICATIONS INFORMATION

## APPLICATIONS INFORMATION

than 100k. If the value of  $R_{BIAS}$  is too large, the filters will not receive a large enough bias current, possibly causing errors due to insufficient settling. Be sure to obey the absolute maximum specifications when driving a clock into CLKIO (Pin 15).

### Input Common Mode and Differential Voltage Range

The input signal range extends from zero to the  $V_{+IN}$  supply voltage. This input supply can be tied to  $V_{+A}$  and  $V_{+D}$ , or driven up to 5.5V for increased input signal range. Figure 9 shows the distortion of the filter versus common mode input voltage with a 2V<sub>P-P</sub> differential input signal ( $V_{+IN} = 5V$ ).

Figure 9. Distortion vs Common Mode Input Voltage (5V)

For best performance, the inputs should be driven differentially. For single-ended signals, connect the unused input to  $V_{OCM}$  (Pin 3) or to a quiet DC reference voltage. To achieve the best distortion performance, the input signal should be centered around the DC voltage of the unused input.

Refer to the Typical Performance Characteristics section to estimate the distortion for a given input level.

### Dynamic Input Impedance

The unique input sampling structure of the LTC6603 has a dynamic input impedance which depends on the configuration and the clock frequency. This dynamic input impedance has both a differential component and a common mode component. The common mode input impedance is a function of the clock frequency and the

control bits LPF1 and LPF0. The differential input impedance is a function of the clock frequency and the control bits LPF1, LPF0, GAIN1 and GAIN0. Table 5 shows the typical input impedances for a clock frequency of 80MHz. These input impedances are all proportional to  $1/f_{CLK}$ , so if the clock frequency were reduced by half to 40MHz, the impedances would be doubled. The typical variation in dynamic input impedance for a given clock frequency is -20% to +35%.

Table 5. Differential, Common Mode Input Impedances,  $f_{CLK} = 80MHz$

1	1	0	0	5.2	40
1	1	0	1	2.8	20
1	1	1	0	1.6	5
1	1	1	1	1.6	5

### Output Common Mode and Differential Voltage Range

The output voltage is a fully differential signal with a common mode level equal to the voltage at  $V_{OCM}$ . Any of the filter outputs may be used as single-ended outputs, although this will degrade the performance. The output voltage range is typically 0.5V to  $V_{+A} - 0.5V$  ( $V_{+A} = 2.7V$  to 3.6V).

The common mode output voltage can be adjusted by overdriving the voltage present on  $V_{OCM}$ . To maximize the undistorted peak-to-peak signal swing of the filter, the  $V_{OCM}$  voltage should be set to  $V_{+A}/2$ . Note that the output common mode voltages of the two channels are

## APPLICATIONS INFORMATION

not independent as they are both set by the  $V_{OCM}$  pin. Figure 10 illustrates the distortion versus output common mode voltage for a  $2V_{P-P}$  differential input voltage and a common mode input voltage that is equal to mid-supply.

Figure 10. Distortion vs Common Mode Output Voltage

### Interfacing to the LTC6603

The input and output common mode voltages of the LTC6603 are independent. The input common mode voltage is set by the signal source if DC-coupled, as shown in Figure 11. If the inputs are AC-coupled, as shown in Figure 12 (Circuit A), the input common mode voltage will be pulled to ground by an equivalent resistance of  $R_{CM}$ , shown in Table 5. This does not affect the filter's performance as long as the input amplitude is less than  $0.5V_{P-P}$ . At low filter gain settings, a larger input voltage swing may be desired.

Figure 11. DC-Coupled Inputs

Connecting resistors between each input and  $V_{+IN}$  will pull the input common mode voltage up, increasing the input signal swing. The resistance,  $R_{PULL-UP}$ , necessary to set the input common mode voltage,  $V_{ICM}$ , to any desired level can be calculated by

$$R_{PULL-UP} = R_{CM} \left( \frac{V_{SUPPLY}}{V_{ICM}} - 1 \right)$$

where

$$R_{CM} = 40k \cdot 80MHz/f_{CLK} \text{ for LPF1=0, LPF0=0}$$

$$R_{CM} = 20k \cdot 80MHz/f_{CLK} \text{ for LPF1=0, LPF0=1}$$

$$R_{CM} = 5k \cdot 80MHz/f_{CLK} \text{ for LPF1=1}$$

For example, if the lowpass cutoff frequency is set to 2.5MHz, 5k resistors connected between each input and  $V_{+IN}$  will set the input common mode voltage to mid-supply.

Circuit A of Figure 12 is for a fixed CLK and LPF0, LPF1 setting. If the clock varies or the LPF0, LPF1 setting changes then Circuit B of Figure 12 should be used.

Due to the sampled data nature of the filter, an anti-aliasing filter at the inputs is recommended.

The output common mode voltage is equal to the voltage of the  $V_{OCM}$  pin. The  $V_{OCM}$  pin is biased to one-half of the supply voltage by an internal resistive divider (see Block Diagram). To alter the common mode output voltage,  $V_{OCM}$  can be driven with an external voltage source or resistor network. If external resistors are used, it is important to note that the internal 2k resistors can vary  $\pm 30\%$  (their ratio varies only  $\pm 1\%$ ). The filter outputs can also be AC-coupled.

The LTC6603 can be interfaced to an A/D converter by pulling CLKCNTL (Pin 5) to  $V_{+D}$ . This configures CLKIO (Pin 15) as a clock output, which can be used to drive the clock input of the A/D converter. This allows the A/D converter to be synchronized with the filter sampling clock, avoiding "beat frequencies" and simplifying the board layout. Any routing attached to the CLKIO pin should be as short as possible, in order to minimize reflections.

Similarly, the LTC6603 can be interfaced to another LTC6603 in a master/slave configuration as shown in Figure 13. This

6603 F12

Figure 12. AC-Coupled Inputs

6603 F13

Figure 13. Two Devices in a Master/Slave Clocking Configuration

## APPLICATIONS INFORMATION

results in four matched filter channels, all synchronized to the same clock. The master has its CLKCNTL pin pulled to  $V_{+D}$ , configuring its CLKIO pin as an output, while the slave has its CLKCNTL pin pulled to ground, configuring its CLKIO pin as an input. Note that in order to synchronize the two filters, the clock frequency must not be buffered. This requires that the filters be close together on the PC board. If the clock is buffered, the filters would have matching bandwidths, but would not be synchronized.

### Output Drive

The filter outputs can drive 1k and/or 50pF loads connected to AC ground with a 0.5V to 2.5V signal (corresponding to a  $4V_{P-P}$  differential signal). For differential loads (loads connected between +OUTA and –OUTA or +OUTB and –OUTB) the outputs can produce a  $4V_{P-P}$  signal across 2k and/or 25pF. For smaller signal amplitudes, the outputs can drive correspondingly larger loads. For larger capacitive loads, an external 50 $\Omega$  series resistor is recommended for each output.

### Clock Feedthrough

Clock feedthrough is defined as the RMS value of the clock frequency and its harmonics that are present at the filter's output. The clock feedthrough is measured with +INA and –INA (or +INB, –INB) tied to  $V_{OCM}$  and depends on the PC board layout and the power supply decoupling. The clock feedthrough can be reduced with a simple RC post filter.

### Decoupling Capacitors

The LTC6603 uses sampling techniques, therefore its performance is sensitive to supply noise. 0.1 $\mu$ F ceramic decoupling capacitors must be connected from  $V_{+A}$  (Pin 2) and  $V_{+D}$  (Pin 16) to ground with leads as short as possible. A ground plane should be used. Noisy signals should be isolated from the filter's input pins. In addition, a 0.1 $\mu$ F decoupling capacitor at Pin 20 is recommended since this pin receives clocked current injection.

### Aliasing

Aliasing is an inherent phenomenon of sampled data filters. Significant aliasing only occurs when the frequency of the input signal approaches the sampling frequency or

multiples of the sampling frequency. The ratio of the LTC6603 input sampling frequency to the clock frequency,  $f_{CLK}$ , is determined by the state of control bits LPF1 and LPF0. Table 6 shows the possible input sampling frequencies for a clock frequency of 80MHz. The input sampling frequency is proportional to the clock frequency. For example, if the clock frequency is lowered from 80MHz to 40MHz, the input sampling frequency will be lowered by half. Input signals with frequencies near the input sampling frequency will be aliased to the passband of the filter and appear at the output unattenuated.

**Table 6. Input Sampling Frequency ( $f_{CLK} = 80\text{MHz}$ )**

LPF1	LPF0	Input Sampling Frequency (MHz)
0	0	20
0	1	40
1	0	160
1	1	160

A simple LC anti-aliasing filter is recommended at the filter inputs to attenuate frequencies near the input sampling frequency that will be aliased to the passband. For example, if the clock frequency is set to 80MHz and the cutoff frequency of the filter is set to its maximum (LPF1 = 1), the lowest frequency that would be aliased to the passband would be  $f_{CLK} - f_{CUTOFF}$ , i.e.,  $160\text{MHz} - 2.5\text{MHz} = 157.5\text{MHz}$ . The LTC6603 filter inputs should be driven by a low impedance output (<100 $\Omega$ ).

### Wideband Noise

The wideband noise of the filter is the RMS value of the device's output noise spectral density. The wideband noise is nearly independent of the value of the clock frequency and excludes the clock feedthrough. Most of the wideband noise is concentrated in the filter passband and cannot be removed with post filtering.

### Power Supply Current

The power supply current depends on the state of the lowpass cutoff frequency controls (LPF1, LPF0) and the value of  $R_{BIAS}$ . When the LTC6603 is programmed for the middle cutoff frequency (LPF1 = 0, LPF0 = 1), the supply current is reduced by about 23% relative to the supply current for the higher bandwidth setting. Programming

## APPLICATIONS INFORMATION

the LTC6603 for the lowest cutoff frequency (LPF1 = 0, LPF0 = 0) reduces the supply current by about 60%. Power supply current vs. cutoff frequency for various bandwidth settings is shown in the Typical Performance Characteristics section. The LTC6603 can be programmed through the serial interface to enter into a low power shutdown mode. The power supply current during shutdown is less than 235 $\mu$ A.

### Supply Current vs Noise Trade-Off

The passband of the LTC6603 is determined by the master clock frequency (which is set by  $R_{BIAS}$  when the internal oscillator is used), LPF1 and LPF0. The LTC6603 is optimized for use with  $R_{BIAS}$  having a value between 200k and 30.9k to set the internal oscillation frequency from 12.36MHz to 80MHz. The lowpass corner frequency is proportional to the clock frequency (internal or external).

To extend the filter's operational frequency range, the master clock is divided down before reaching the filter. LPF1 and LPF0 set the division ratio of the lowpass clock. Figure 14 shows the possible cutoff frequencies versus  $f_{CLK}$ , LPF1 and LPF0. Overlapping frequency ranges allow more than one possible choice of bandwidth settings for some cutoff frequencies. Figure 15 shows supply current as a function of the filter cutoff frequency, LPF1 and LPF0. Note that the higher bandwidth setting always gives the minimum supply current for a given cutoff frequency. The input referred integrated noise voltage for a passband gain of 24dB is shown in Table 7. Note that the noise is higher for the higher bandwidth settings. This creates a tradeoff between supply current and noise. For a given cutoff frequency, using the highest possible bandwidth setting gives the minimum supply current at the expense of higher noise.

LTC1567	Very Low Noise, High Frequency Filter Building Block	1.4nV/ $\sqrt{\text{Hz}}$ Op Amp, MSOP Package, Differential Outputs
LTC1568	Very Low Noise, 4th Order Building Block	Lowpass and Bandpass Filter Designs Up to 10MHz, Differential Outputs
LTC1569-6	Low Power 10-Pole Delay Equalized Elliptic Lowpass	$f_c \leq 64\text{kHz}$ , One Resistor Sets $f_c$ , SO-8 Differential Inputs
LTC1569-7	10-Pole Delay Equalized Elliptic Lowpass	$f_c \leq 256\text{kHz}$ , One Resistor Sets $f_c$ , SO-8 Differential Inputs
LT1994	Low Distortion, Low Noise Differential Amplifier/ADC Driver	Adjustable, Low Power, $V_S = 2.375\text{V}$ to $12.6\text{V}$
LTC6406	3GHz Low Noise, Rail-to-Rail Input Differential ADC Driver	Low Noise: $1.6\text{nV}/\sqrt{\text{Hz}}$ , Low Power: $18\mu\text{A}$
LT6600-2.5	Very Low Noise, Fully Differential Amplifier and 2.5MHz Filter	86dB S/N with 3V Supply, SO-8 Package
LT6600-5	Very Low Noise, Fully Differential Amplifier and 5MHz Filter	82dB S/N with 3V Supply, SO-8 Package
LT6600-10	Very Low Noise, Fully Differential Amplifier and 10MHz Filter	82dB S/N with 3V Supply, SO-8 Package
LT6600-15	Very Low Noise, Fully Differential Amplifier and 15MHz Filter	76dB S/N with 3V Supply, SO-8 Package
LT6600-20	Very Low Noise, Fully Differential Amplifier and 20MHz Filter	76dB S/N with 3V Supply, SO-8 Package
LTC6601	Pin-Configurable Second Order Filter/Driver	$f_c$ 7MHz to 27MHz Fully Differential 4mm $\times$ 4mm QFN Package
LTC6602	Dual Baseband Bandpass Filter for UHF RFID	Fully Differential 4mm $\times$ 4mm QFN Package
LTC6604-2.5	Dual Very Low Noise, Differential Amp and 2.5MHz Filter	86dB S/N with 3V Supply, 4mm $\times$ 7mm QFN Package
LTC6604-5	Dual Very Low Noise, Differential Amp and 5MHz Filter	82dB S/N with 3V Supply, 4mm $\times$ 7mm QFN Package
LTC6604-10	Dual Very Low Noise, Differential Amp and 10MHz Filter	82dB S/N with 3V Supply, 4mm $\times$ 7mm QFN Package
LTC6604-15	Dual Very Low Noise, Differential Amp and 15MHz Filter	76dB S/N with 3V Supply, 4mm $\times$ 7mm QFN Package

Компания «Океан Электроники» предлагает заключение долгосрочных отношений при поставках импортных электронных компонентов на взаимовыгодных условиях!

Наши преимущества:

- Поставка оригинальных импортных электронных компонентов напрямую с производств Америки, Европы и Азии, а так же с крупнейших складов мира;
- Широкая линейка поставок активных и пассивных импортных электронных компонентов (более 30 млн. наименований);
- Поставка сложных, дефицитных, либо снятых с производства позиций;
- Оперативные сроки поставки под заказ (от 5 рабочих дней);
- Экспресс доставка в любую точку России;
- Помощь Конструкторского Отдела и консультации квалифицированных инженеров;
- Техническая поддержка проекта, помощь в подборе аналогов, поставка прототипов;
- Поставка электронных компонентов под контролем ВП;
- Система менеджмента качества сертифицирована по Международному стандарту ISO 9001;
- При необходимости вся продукция военного и аэрокосмического назначения проходит испытания и сертификацию в лаборатории (по согласованию с заказчиком);
- Поставка специализированных компонентов военного и аэрокосмического уровня качества (Xilinx, Altera, Analog Devices, Intersil, Interpoint, Microsemi, Actel, Aeroflex, Peregrine, VPT, Syfer, Eurofarad, Texas Instruments, MS Kennedy, Miteq, Cobham, E2V, MA-COM, Hittite, Mini-Circuits, General Dynamics и др.);

Компания «Океан Электроники» является официальным дистрибьютором и эксклюзивным представителем в России одного из крупнейших производителей разъемов военного и аэрокосмического назначения «JONHON», а так же официальным дистрибьютором и эксклюзивным представителем в России производителя высокотехнологичных и надежных решений для передачи СВЧ сигналов «FORSTAR».

## JONHON

«JONHON» (основан в 1970 г.)

Разъемы специального, военного и аэрокосмического назначения:

(Применяются в военной, авиационной, аэрокосмической, морской, железнодорожной, горно- и нефтедобывающей отраслях промышленности)

«FORSTAR» (основан в 1998 г.)

ВЧ соединители, коаксиальные кабели,  
кабельные сборки и микроволновые компоненты:

(Применяются в телекоммуникациях гражданского и специального назначения, в средствах связи, РЛС, а так же военной, авиационной и аэрокосмической отраслях промышленности).
