## High Bandwidth, Analog/Video Optocouplers

## Data Sheet

### Description

The HCPL-4562 and HCNW4562 optocouplers provide wide bandwidth isolation for analog signals. They are ideal for video isolation when combined with their application circuit (Figure 4). High linearity and low phase shift are achieved through an AlGaAs LED combined with a high speed detector. These single channel optocouplers are available in 8-Pin DIP and Widebody package configurations.

## Conversion from HCPL-4562 to HCNW4562

In order to obtain similar circuit performance when converting from the HCPL-4562 to the HCNW4562, it is recommended to increase the Quiescent Input Current,  $I_{FQ}$ , from 6 mA to 10 mA. If the application circuit in Figure 4 is used, then potentiometer R4 should be adjusted appropriately.

### Design Considerations of the Application Circuit

The application circuit in Figure 4 incorporates several features that help maximize the bandwidth performance of the HCPL-4562/HCNW4562. Most important of these features is peaked response of the detector circuit that helps extend the frequency range over which the voltage gain is relatively constant. The number of gain stages, the overall circuit topology, and the choice of DC bias points are all consequences of the desire to maximize bandwidth performance.

To use the circuit, first select  $R_1$  to set  $V_E$  for the desired LED quiescent current by:

$$I_{FQ} = \frac{V_E}{R_4} \approx \frac{G_V V_E R_{10}}{(I_{PB}/I_F) R_7 R_9} \quad (1)$$

For a constant value  $V_{INP-P}$ , the circuit topology (adjusting the gain with  $R_4$ ) preserves linearity by keeping the modulation factor (MF) dependent only on  $V_E$ .

$$i_{Fp-p} \approx V_{IN}/R_4 \quad (2)$$

$$\frac{i_{Fp-p}}{I_{FQ}} \approx \frac{i_{PBp-p}}{I_{PBQ}} = \frac{V_{INp-p}}{V_E} \quad (3)$$

Modulation

$$\text{Factor (MF): } \frac{i_{F(p-p)}}{2 I_{FQ}} = \frac{V_{INp-p}}{2 V_E} \quad (4)$$

For a given  $G_V$ ,  $V_E$ , and  $V_{CC}$ , DC output voltage will vary only with  $h_{FEX}$ .

$$V_O = V_{CC} - V_{BE4} - \frac{R_9}{R_{10}} [V_{BEX} - (I_{PBQ} - I_{BXQ}) R_7] \quad (5)$$

Where:

$$I_{PBQ} \approx \frac{G_V V_E R_{10}}{R_7 R_9} \quad (6)$$

and,

$$I_{BXQ} \approx \frac{V_{CC} - 2 V_{BE}}{R_6 h_{FEX}} \quad (7)$$

Figure 15 shows the dependency of the DC output voltage on  $h_{FEX}$ .

For  $9V < V_{CC} < 12V$ , select the value of  $R_{11}$  such that

$$I_{CQ4} \approx \frac{V_O}{R_{11}} = \frac{4.25V}{470} = 9.0 \text{ mA} \quad (8)$$

The voltage gain of the second stage ( $Q_3$ ) is approximately equal to:

$$\frac{R_9}{R_{10}} * \frac{1}{1 + s R_9 \left[ C_{CQ3} + \frac{1}{2 R_{11} f_{T4}} \right]} \quad (9)$$

Increasing  $R'_{11}$  ( $R'_{11}$  includes the parallel combination of  $R_{11}$  and the load impedance) or reducing  $R_9$  (keeping  $R_9/R_{10}$  ratio constant) will improve the bandwidth.

If it is necessary to drive a low impedance load, bandwidth may also be preserved by adding an additional emitter following the buffer stage ( $Q_5$  in Figure 16), in which case  $R_{11}$  can be increased to set  $I_{CQ4} \approx 2 \text{ mA}$ .

Finally, adjust  $R_4$  to achieve the desired voltage gain.

$$G_V \approx \frac{V_{OUT}}{V_{IN}} \approx \frac{I_{PB}}{I_F} \left[ \frac{R_7 R_9}{R_4 R_{10}} \right] \quad (10)$$

where typically  $\frac{I_{PB}}{I_F} = 0.0032$
