Absolute Maximum Ratings

Stresses above the ratings listed below can cause permanent damage to the IDT6V31021. These ratings, which are standard values for IDT commercially rated parts, are stress ratings only. Functional operation of the device at these or any other conditions above those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods can affect product reliability. Electrical parameters are guaranteed only over the recommended operating temperature range.

Notes on Electrical Characteristics (all measurements use $R_S=33\text{ohms}/C_L=2\text{pF}$ test load):

¹ Guaranteed by design and characterization, not 100% tested in production.

² Slew rate measured through V_{swing} centered around differential zero

³ V_{xabs} is defined as the voltage where $CLK = CLK\#$

⁴ Only applies to the differential rising edge (CLK rising and CLK# falling)

⁵ Defined as the total variation of all crossing voltages of CLK rising and CLK# falling. Matching applies to rising edge rate of CLK and falling edge of CLK#. It is measured using a +/-75mV window centered on the average cross point where CLK meets CLK#.

⁶ This figure refers to the maximum distortion of the input wave form.

⁷ Operation under these conditions is neither implied, nor guaranteed.

⁸ Maximum input voltage is not to exceed maximum VDD

⁹ The 6V31021 has no PLL, so the part itself contributes very little jitter to the input clock. But this also means that the 9DBL411 cannot 'de-jitter' a noisy input clock. Values calculated per PCI SIG and per Intel Clock Jitter tool version 1.6.6. For PCIe RMS figures, additive jitter is calculated by solving the following equation: Additive jitter = $\text{SQRT}[(\text{total jitter})^2 - (\text{input jitter})^2]$

¹⁰ Calculated from Agilent E5052A phase noise machine.

¹¹ Mean value not including cycle-to-cycle jitter
