**Note:** The SGND and PGND pins of the IS31AP4912 must be routed separately back to the decoupling capacitor in order to provide proper device operation. If the SGND and PGND pins are connected directly to each other, the part functions without risk of failure, but the noise and THD performance do not meet the specifications.

## APPLICATION INFORMATION

### CHARGE PUMP CONVERTER

IS31AP4912 integrate a charge pump converter to change input supply voltage ( $V_{CC}$ ) into a negative voltage providing a 0V reference voltage for output.

The charge pump converter only needs three external components: supply decoupling capacitor, output bypass capacitor and flying capacitor.

Choose low ESR capacitors to ensure the best operating performance and place the capacitors as close as possible to the IS31AP4912.

### GAIN SETTING

The input resistors ( $R_{IN}$ ) and feedback resistors ( $R_F$ ) set the gain of the amplifier according to Equation (1).

$$Gain = \frac{R_F}{R_{IN}} \left( \frac{V}{V} \right) \quad (1)$$

For example, in figure 1:

$R_F = 20k\Omega$ ,  $R_{IN} = 20k\Omega$ ,

$$\text{so,} \quad Gain = \frac{20}{20} = 1 \left( \frac{V}{V} \right)$$

Resistor matching is very important in the amplifiers. The balance of the output on the reference voltage depends on matched ratios of the resistors. CMRR, PSRR, and cancellation of the second harmonic distortion diminish if resistor mismatch occurs. Therefore, it is recommended to use 1% tolerance resistors or better to keep the performance optimized. Matching is more important than overall tolerance. Resistor arrays with 1% matching can be used with a tolerance greater than 1%.

Place the input resistors very close to the IS31AP4912 to limit noise injection on the high-impedance nodes.

### INPUT CAPACITOR ( $C_{IN}$ )

The input capacitors and input resistors form a high pass filter with the corner frequency,  $f_c$ , determined in Equation (2).

$$f_c = \frac{1}{2\pi R_{IN} C_{IN}} \quad (2)$$

For example, in figure 1:

$R_{IN} = 20k\Omega$ ,  $C_{IN} = 0.47\mu F$ ,

$$\text{so,} \quad f_c = \frac{1}{2\pi \times 20k\Omega \times 0.47\mu F} \approx 17Hz$$

The value of the input capacitor is important to consider as it directly affects the bass (low frequency) performance of the circuit. The capacitors should have a tolerance of  $\pm 10\%$  or better, because any mismatch in capacitance causes an impedance mismatch at the corner frequency and below.

### DESIGN NOTE

#### COMPONENT SELECTION

The value and ESR of the output capacitor for charge pump will affect output ripple and transient performance. A X7R or X5R ceramic capacitor in  $2.2\mu F$  should be recommended. The flying capacitor should use a  $2.2\mu F$  X7R or X5R ceramic capacitor.

All the capacitors should support at least 10V.

### PCB LAYOUT

The decoupling capacitors should be placed close to the VCC pin and the output capacitors should be placed close to the VSS pin. The flying capacitor should be placed close to the CN and CP pins. The input capacitors and input resistors should be placed close to the INR and INL pins and the traces must be parallel to prevent noise. The traces of OUTR and OUTL pins connected to the headphone should be as possible as short and wide. The recommended width is 0.5mm.

Trace width should be at least 0.75mm for the power supply and the ground plane. The SGND and PGND pins of the IS31AP4912 must be routed separately back to the decoupling capacitor in order to provide proper device operation. If the SGND and PGND pins are connected directly to each other, the part functions without risk of failure, but the noise and THD performance do not meet the specifications.
