TMS320C54x, TMS320LC54x, TMS320VC54x FIXED-POINT DIGITAL SIGNAL PROCESSORS

SPRS039C – FEBRUARY 1996 – REVISED DECEMBER 1999

description

The TMS320C54x, TMS320LC54x, and TMS320VC54x fixed-point, digital signal processor (DSP) families (hereafter referred to as the '54x unless otherwise specified) are based on an advanced modified Harvard architecture that has one program memory bus and three data memory buses. These processors also provide an arithmetic logic unit (ALU) that has a high degree of parallelism, application-specific hardware logic, on-chip memory, and additional on-chip peripherals. These DSP families also provide a highly specialized instruction set, which is the basis of the operational flexibility and speed of these DSPs.

Separate program and data spaces allow simultaneous access to program instructions and data, providing the high degree of parallelism. Two reads and one write operation can be performed in a single cycle. Instructions with parallel store and application-specific instructions can fully utilize this architecture. In addition, data can be transferred between data and program spaces. Such parallelism supports a powerful set of arithmetic, logic, and bit-manipulation operations that can all be performed in a single machine cycle. In addition, the 'C54x, 'LC54x, and 'VC54x versions include the control mechanisms to manage interrupts, repeated operations, and function calls.

Table 1 provides an overview of the '54x generation of DSPs. The table shows significant features of each device including the capacity of on-chip RAM and ROM memories, the peripherals, the execution time of one machine cycle, and the type of package with its total pin count.

Table 1. Characteristics of the '54x Processors

| DSP TYPE | NOMINAL VOLTAGE (V) | ON-CHIP MEMORY | | PERIPHERALS | | | CYCLE TIME (ns) | PACKAGE TYPE |

SPRS039C – FEBRUARY 1996 – REVISED DECEMBER 1999

'54x Signal Descriptions

| TERMINAL NAME | TYPE† | DESCRIPTION |
|---|-------|--|
| DATA SIGNALS | | |
| A22 (MSB) A21 A20 A19 A18 A17 A16 A15 A14 A13 A12 A11 A10 A9 A8 A7 A6 A5 A4 A3 A2 A1 A0 (LSB) | O/Z | Parallel port address bus A22 (MSB) through A0 (LSB). The sixteen LSBs (A15–A0) are multiplexed to address external data/program memory or I/O. A15–A0 are placed in the high-impedance state in the hold mode. A15–A0 also go into the high-impedance state when EMU1/OFF is low. The seven MSBs (A22 to A16) are used for extended program memory addressing ('548 and '549 only). On the '548 and '549 devices, the address bus have a feature called bus holder that eliminates passive components and the power dissipation associated with it. The bus holders keep the address bus at the previous logic level when the bus goes into a high-impedance state. The bus holders on the address bus are always enabled. |
| D15 (MSB) D14 D13 D12 D11 D10 D9 D8 D7 D6 D5 D4 D3 D2 D1 D0 (LSB) | I/O/Z | Parallel port data bus D15 (MSB) through D0 (LSB). D15–D0 are multiplexed to transfer data between the core CPU and external data/program memory or I/O devices. D15–D0 are placed in the high-impedance state when not output or when RS or HOLD is asserted. D15–D0 also go into the high-impedance state when EMU1/OFF is low. The data bus has a feature called bus holder that eliminates passive components and the power dissipation associated with it. The bus holders keep the data bus at the previous logic level when the bus goes into a high-impedance state. These bus holders are enabled or disabled by the BH bit in the bank switching control register (BSCR). |
| INITIALIZATION, INTERRUPT AND RESET OPERATIONS | | |
| $\overline{\text{IACK}}$ | O/Z | Interrupt acknowledge signal. $\overline{\text{IACK}}$ indicates the receipt of an interrupt and that the program counter is fetching the interrupt vector location designated by A15–0. $\overline{\text{IACK}}$ also goes into the high-impedance state when EMU1/OFF is low. |
| $\overline{\text{INT0}}$ $\overline{\text{INT1}}$ $\overline{\text{INT2}}$ $\overline{\text{INT3}}$ | I | External user interrupt inputs. $\overline{\text{INT0}}$ – $\overline{\text{INT3}}$ are prioritized and are maskable by the interrupt mask register and the interrupt mode bit. $\overline{\text{INT0}}$ – $\overline{\text{INT3}}$ can be polled and reset by the interrupt flag register. |

† I = Input, O = Output, Z = High impedance

'54x Signal Descriptions (Continued)

| TERMINAL NAME | TYPE† | DESCRIPTION |
|--|-------|--|
| INITIALIZATION, INTERRUPT AND RESET OPERATIONS (CONTINUED) | | |
| $\overline{\text{NMI}}$ | I | Nonmaskable interrupt. $\overline{\text{NMI}}$ is an external interrupt that cannot be masked by way of the INTM or the IMR. When $\overline{\text{NMI}}$ is activated, the processor traps to the appropriate vector location. |
| $\overline{\text{RS}}$ | I | Reset input. $\overline{\text{RS}}$ causes the DSP to terminate execution and forces the program counter to 0FF80h. When $\overline{\text{RS}}$ is brought to a high level, execution begins at location 0FF80h of the program memory. $\overline{\text{RS}}$ affects various registers and status bits. |
| MP/ $\overline{\text{MC}}$ | I | Microprocessor/microcomputer mode-select pin. If active-low at reset (microcomputer mode), MP/ $\overline{\text{MC}}$ causes the internal program ROM to be mapped into the upper program memory space. In the microprocessor mode, off-chip memory and its corresponding addresses (instead of internal program ROM) are accessed by the DSP. |
| CNT | I | I/O level select. For 5-V operation, all input and output voltage levels are TTL-compatible when CNT is pulled down to a low level. For 3-V operation with CMOS-compatible I/O interface levels, CNT is pulled to a high level. |
| MULTIPROCESSING SIGNALS | | |
| $\overline{\text{BIO}}$ | I | Branch control input. A branch can be conditionally executed when $\overline{\text{BIO}}$ is active. If low, the processor executes the conditional instruction. The $\overline{\text{BIO}}$ condition is sampled during the decode phase of the pipeline for the XC instruction, and all other instructions sample $\overline{\text{BIO}}$ during the read phase of the pipeline. |
| XF | O/Z | External flag output (latched software-programmable signal). XF is set high by the SSBX XF instruction, set low by RSBX XF instruction or by loading the ST1 status register. XF is used for signaling other processors in multiprocessor configurations or as a general-purpose output pin. XF goes into the high-impedance state when $\overline{\text{OFF}}$ is low, and is set high at reset. |
| MEMORY CONTROL SIGNALS | | |
| $\overline{\text{DS}}$ $\overline{\text{PS}}$ $\overline{\text{IS}}$ | O/Z | Data, program, and I/O space select signals. $\overline{\text{DS}}$, $\overline{\text{PS}}$, and $\overline{\text{IS}}$ are always high unless driven low for communicating to a particular external space. Active period corresponds to valid address information. Placed into a high-impedance state in hold mode. $\overline{\text{DS}}$, $\overline{\text{PS}}$, and $\overline{\text{IS}}$ also go into the high-impedance state when EMU1/ $\overline{\text{OFF}}$ is low. |
| $\overline{\text{MSTRB}}$ | O/Z | Memory strobe signal. $\overline{\text{MSTRB}}$ is always high unless low-level asserted to indicate an external bus access to data or program memory. Placed in high-impedance state in hold mode. $\overline{\text{MSTRB}}$ also goes into the high-impedance state when $\overline{\text{OFF}}$ is low. |
| READY | I | Data-ready input. READY indicates that an external device is prepared for a bus transaction to be completed. If the device is not ready (READY is low), the processor waits one cycle and checks READY again. Note that the processor performs ready-detection if at least two software wait states are programmed. The READY signal is not sampled until the completion of the software wait states. |
| R/ $\overline{\text{W}}$ | O/Z | Read/write signal. R/ $\overline{\text{W}}$ indicates transfer direction during communication to an external device and is normally high (in read mode), unless asserted low when the DSP performs a write operation. Placed in the high-impedance state in hold mode, R/ $\overline{\text{W}}$ also goes into the high-impedance state when EMU1/ $\overline{\text{OFF}}$ is low. |
| $\overline{\text{IOSTRB}}$ | O/Z | I/O strobe signal. $\overline{\text{IOSTRB}}$ is always high unless low level asserted to indicate an external bus access to an I/O device. Placed in high-impedance state in hold mode. $\overline{\text{IOSTRB}}$ also goes into the high-impedance state when EMU1/ $\overline{\text{OFF}}$ is low. |
| $\overline{\text{HOLD}}$ | I | Hold input. $\overline{\text{HOLD}}$ is asserted to request control of the address, data, and control lines. When acknowledged by the '54x, these lines go into high-impedance state. |
| $\overline{\text{HOLDA}}$ | O/Z | Hold acknowledge signal. $\overline{\text{HOLDA}}$ indicates to the external circuitry that the processor is in a hold state and that the address, data, and control lines are in a high-impedance state, allowing them to be available to the external circuitry. $\overline{\text{HOLDA}}$ also goes into the high-impedance state when EMU1/ $\overline{\text{OFF}}$ is low. |
| $\overline{\text{MSC}}$ | O/Z | Microstate complete signal. Goes low on CLKOUT falling at the start of the first software wait state. Remains low until one CLKOUT cycle before the last programmed software wait state. If connected to the READY line, $\overline{\text{MSC}}$ forces one external wait state after the last internal wait state has been completed. $\overline{\text{MSC}}$ also goes into the high-impedance state when EM1/ $\overline{\text{OFF}}$ is low. |

† I = Input, O = Output, Z = High impedance

'54x Signal Descriptions (Continued)

| TERMINAL NAME | TYPE† | DESCRIPTION |
|--|-------|--|
| MEMORY CONTROL SIGNALS (CONTINUED) | | |
| $\overline{\text{IAQ}}$ | O/Z | Instruction acquisition signal. $\overline{\text{IAQ}}$ is asserted (active low) when there is an instruction address on the address bus and goes into the high-impedance state when EMU1/OFF is low. |
| OSCILLATOR/TIMER SIGNALS | | |
| CLKOUT | O/Z | Master clock output signal. CLKOUT cycles at the machine-cycle rate of the CPU. The internal machine cycle is bounded by the falling edges of this signal. CLKOUT also goes into the high-impedance state when EMU1/OFF is low. |
| CLKMD1 CLKMD2 CLKMD3 | I | Clock mode external/internal input signals. CLKMD1, CLKMD2, and CLKMD3 allow you to select and configure different clock modes, such as crystal, external clock, and various PLL factors. Refer to PLL section for a detailed functional description of these pins. |
| X2/CLKIN | I | Input pin to internal oscillator from the crystal. If the internal (crystal) oscillator is not being used, a clock can become input to the device using this pin. The internal machine cycle time is determined by the clock operating-mode pins (CLKMD1, CLKMD2 and CLKMD3). |
| X1 | O | Output pin from the internal oscillator for the crystal. If the internal oscillator is not used, X1 should be left unconnected. X1 does not go into the high-impedance state when EMU1/OFF is low. |
| TOUT | O/Z | Timer output. TOUT signals a pulse when the on-chip timer counts down past zero. The pulse is a CLKOUT-cycle wide. TOUT also goes into the high-impedance state when EMU1/OFF is low. |
| BUFFERED SERIAL PORT 0 AND BUFFERED SERIAL PORT 1 SIGNALS | | |
| BCLKR0 BCLKR1 | I | Receive clocks. External clock signal for clocking data from the data-receive (DR) pin into the buffered serial port receive shift registers (RSRs). Must be present during buffered serial port transfers. If the buffered serial port is not being used, BCLKR0 and BCLKR1 can be sampled as an input by way of IN0 bit of the SPC register. |
| BCLKX0 BCLKX1 | I/O/Z | Transmit clock. Clock signal for clocking data from the serial port transmit shift register (XSR) to the data transmit (DX) pin. BCLKX can be an input if MCM in the serial port control register is cleared to 0. It also can be driven by the device at $1/(\text{CLKDV} + 1)$ where CLKDV range is 0–31 CLKOUT frequency when MCM is set to 1. If the buffered serial port is not used, BCLKX can be sampled as an input by way of IN1 of the SPC register. BCLKX0 and BCLKX1 go into the high-impedance state when OFF is low. |
| BDR0 BDR1 | I | Buffered serial-data-receive input. Serial data is received in the RSR by BDR0/BDR1. |
| BDX0 BDX1 | O/Z | Buffered serial-port-transmit output. Serial data is transmitted from the XSR by way of BDX. BDX0 and BDX1 are placed in the high-impedance state when not transmitting and when EMU1/OFF is low. |
| BFSR0 BFSR1 | I | Frame synchronization pulse for receive input. The falling edge of the BFSR pulse initiates the data-receive process, beginning the clocking of the RSR. |
| BFSX0 BFSX1 | I/O/Z | Frame synchronization pulse for transmit input/output. The falling edge of the BFSX pulse initiates the data-transmit process, beginning the clocking of the XSR. Following reset, the default operating condition of BFSX is an input. BFSX0 and BFSX1 can be selected by software to be an output when TXM in the serial control register is set to 1. This pin goes into the high-impedance state when EMU1/OFF is low. |
| SERIAL PORT 0 AND SERIAL PORT 1 SIGNALS | | |
| CLKR0 CLKR1 | I | Receive clocks. External clock signal for clocking data from the data receive (DR) pin into the serial port receive shift register (RSR). Must be present during serial port transfers. If the serial port is not being used, CLKR0 and CLKR1 can be sampled as an input via IN0 bit of the SPC register. |
| CLKX0 CLKX1 | I/O/Z | Transmit clock. Clock signal for clocking data from the serial port transmit shift register (XSR) to the data transmit (DX) pin. CLKX can be an input if MCM in the serial port control register is cleared to 0. It also can be driven by the device at $1/4$ CLKOUT frequency when MCM is set to 1. If the serial port is not used, CLKX can be sampled as an input via IN1 of the SPC register. CLKX0 and CLKX1 go into the high-impedance state when EMU1/OFF is low. |
| DR0 DR1 | I | Serial-data-receive input. Serial data is received in the RSR by DR. |

| DX0 DX1 | O/Z | Serial port transmit output. Serial data is transmitted from the XSR via DX. DX0 and DX1 are placed in the high-impedance state when not transmitting and when EMU1/ÖFF is low. |
| FSR0 FSR1 | I | Frame synchronization pulse for receive input. The falling edge of the FSR pulse initiates the data-receive process, beginning the clocking of the RSR. |
| FSX0 FSX1 | I/O/Z | Frame synchronization pulse for transmit input/output. The falling edge of the FSX pulse initiates the data transmit process, beginning the clocking of the XSR. Following reset, the default operating condition of FSX is an input. FSX0 and FSX1 can be selected by software to be an output when TXM in the serial control register is set to 1. This pin goes into the high-impedance state when EMU1/ÖFF is low. |
| TDM SERIAL PORT SIGNALS | | |
| TCLKR | I | TDM receive clock input |
| TDR | I | TDM serial data-receive input |
| TFSR/TADD | I/O | TDM receive frame synchronization or TDM address |
| TCLKX | I/O/Z | TDM transmit clock |
| TDX | O/Z | TDM serial data-transmit output |
| TFSX/TFRM | I/O/Z | TDM transmit frame synchronization |
| HOST-PORT INTERFACE SIGNALS | | |
| HD0–HD7 | I/O/Z | Parallel bidirectional data bus. HD0–HD7 are placed in the high-impedance state when not outputting data. The signals go into the high-impedance state when EMU1/ÖFF is low. These pins each have bus holders similar to those on the address/data bus, but which are always enabled. |
| HCNTL0 HCNTL1 | I | Control inputs |
| HBIL | I | Byte-identification input |
| HCS | I | Chip-select input |
| HDS1 HDS2 | I | Data strobe inputs |
| HAS | I | Address strobe input |
| HR/W | I | Read/write input |
| HRDY | O/Z | Ready output. This signal goes into the high-impedance state when EMU1/ÖFF is low. |
| HINT | O/Z | Interrupt output. When the DSP is in reset, this signal is driven high. The signal goes into the high-impedance state when EMU1/ÖFF is low. |
| HPIENA | I | HPI module select input. This signal must be tied to a logic 1 state to have HPI selected. If this input is left open or connected to ground, the HPI module will not be selected, internal pullup for the HPI input pins are enabled, and the HPI data bus has keepers set. This input is provided with an internal pull-down resistor which is active only when RS is low. HPIENA is sampled when RS goes high and ignored until RS goes low again. Refer to the Electrical Characteristics section for the input current requirements for this pin. |
| SUPPLY PINS | | |
| CVDD | Supply | +VDD. CVDD is the dedicated power supply for the core CPU. |
| DVDD | Supply | +VDD. DVDD is the dedicated power supply for I/O pins. |
| VSS | Supply | Ground. VSS is the dedicated power ground for the device. |

'54x Signal Descriptions (Continued)

| TERMINAL NAME | TYPE† | DESCRIPTION |
|-----------------------------|-------|--|
| IEEE1149.1 TEST PINS | | |
| TCK | I | IEEE standard 1149.1 test clock. Pin with internal pullup device. This is normally a free-running clock signal with a 50% duty cycle. The changes on the test-access port (TAP) of input signals TMS and TDI are clocked into the TAP controller, instruction register, or selected test data register on the rising edge of TCK. Changes at the TAP output signal (TDO) occur on the falling edge of TCK. |
| TDI | I | IEEE standard 1149.1 test data input. Pin with internal pullup device. TDI is clocked into the selected register (instruction or data) on a rising edge of TCK. |
| TDO | O/Z | IEEE standard 1149.1 test data output. The contents of the selected register (instruction or data) is shifted out of TDO on the falling edge of TCK. TDO is in the high-impedance state except when the scanning of data is in progress. TDO also goes into the high-impedance state when EMU1/OFF is low. |
| TMS | I | IEEE standard 1149.1 test mode select. Pin with internal pullup device. This serial control input is clocked into the TAP controller on the rising edge of TCK. |
| $\overline{\text{TRST}}$ | I | IEEE standard 1149.1 test reset. $\overline{\text{TRST}}$, when high, gives the IEEE standard 1149.1 scan system control of the operations of the device. If $\overline{\text{TRST}}$ is not connected or driven low, the device operates in its functional mode, and the IEEE standard 1149.1 signals are ignored. Pin with internal pulldown device. |
| EMU0 | I/O/Z | Emulator interrupt 0 pin. When $\overline{\text{TRST}}$ is driven low, EMU0 must be high for the activation of the EMU1/OFF condition. When $\overline{\text{TRST}}$ is driven high, EMU0 is used as an interrupt to or from the emulator system and is defined as input/output by way of IEEE standard 1149.1 scan system. |
| EMU1/OFF | I/O/Z | Emulator interrupt 1 pin/disable all outputs. When $\overline{\text{TRST}}$ is driven high, EMU1/OFF is used as an interrupt to or from the emulator system and is defined as input/output by way of IEEE standard 1149.1 scan system. When $\overline{\text{TRST}}$ is driven low, EMU1/OFF is configured as OFF. The EMU1/OFF signal, when active low, puts all output drivers into the high-impedance state. Note that OFF is used exclusively for testing and emulation purposes (not for multiprocessing applications). Therefore, for the OFF condition, the following conditions apply: $\overline{\text{TRST}}$ = low, EMU0 = high EMU1/OFF = low |
| DEVICE TEST PIN | | |
| TEST1 | I | Test1 – Reserved for internal use only ('LC548, 'LC549, and 'VC549 only). This pin must not be connected (NC). |

† I = Input, O = Output, Z = High impedance

architecture

The '54x DSPs use an advanced, modified Harvard architecture that maximizes processing power by maintaining three separate bus structures for data memory and one for program memory. Separate program and data spaces allow simultaneous access to program instructions and data, providing a high degree of parallelism. For example, two read and one write operations can be performed in a single cycle. Instructions with parallel store and application-specific instructions fully utilize this architecture. In addition, data can be transferred between data and program spaces. Such parallelism supports a powerful set of arithmetic, logic, and bit-manipulation operations that can all be performed in a single machine cycle. In addition, the '54x include the control mechanisms to manage interrupts, repeated operations, and function calls.

The functional block diagram includes the principal blocks and bus structure in the '54x devices.

SPRS039C – FEBRUARY 1996 – REVISED DECEMBER 1999

central processing unit (CPU)

The CPU of the '54x devices contains:

- A 40-bit arithmetic logic unit (ALU)
- Two 40-bit accumulators
- A barrel shifter
- A 17×17 -bit multiplier/adder
- A compare, select and store unit (CSSU)

arithmetic logic unit (ALU)

The '54x devices perform 2s-complement arithmetic using: a 40-bit arithmetic logic unit (ALU) and two 40-bit accumulators (ACCA and ACCB). The ALU also can perform Boolean operations.

The ALU can function as two 16-bit ALUs and perform two 16-bit operations simultaneously when the C16 bit in status register 1 (ST1) is set.

accumulators

The accumulators, ACCA and ACCB, store the output from the ALU or the multiplier / adder block; the accumulators can also provide a second input to the ALU or the multiplier / adder. The accumulators are divided into three parts:

- Guard bits (bits 32–39)
- A high-order word (bits 16–31)
- A low-order word (bits 0–15)

Instructions are provided for storing the guard bits, the high- and the low-order accumulator words in data memory, and for manipulating 32-bit accumulator words in or out of data memory. Also, any of the accumulators can be used as temporary storage for the other.

barrel shifter

The '54x's barrel shifter has a 40-bit input connected to the accumulator, or data memory (CB, DB) and a 40-bit output connected to the ALU, or data memory (EB). The barrel shifter produces a left shift of 0 to 31 bits and a right shift of 0 to 16 bits on the input data. The shift requirements are defined in the shift-count field (ASM) of ST1 or defined in the temporary register (TREG), which is designated as a shift-count register. This shifter and the exponent detector normalize the values in an accumulator in a single cycle. The least significant bits (LSBs) of the output are filled with 0s and the most significant bits (MSBs) can be either zero-filled or sign-extended, depending on the state of the sign-extended mode bit (SXM) of ST1. Additional shift capabilities enable the processor to perform numerical scaling, bit extraction, extended arithmetic, and overflow prevention operations.

multiplier/adder

The multiplier / adder performs 17×17 -bit 2s-complement multiplication with a 40-bit accumulation in a single instruction cycle. The multiplier / adder block consists of several elements: a multiplier, adder, signed / unsigned input control, fractional control, a zero detector, a rounder (2s-complement), overflow / saturation logic, and TREG. The multiplier has two inputs: one input is selected from the TREG, a data-memory operand, or an accumulator; the other is selected from the program memory, the data memory, an accumulator, or an immediate value. The fast on-chip multiplier allows the '54x to perform operations such as convolution, correlation, and filtering efficiently.

In addition, the multiplier and ALU together execute multiply/accumulate (MAC) computations and ALU operations in parallel in a single instruction cycle. This function is used in determining the Euclid distance, and in implementing symmetrical and least mean square (LMS) filters, which are required for complex DSP algorithms.

compare, select and store unit (CSSU)

The compare, select and store unit (CSSU) performs maximum comparisons between the accumulator's high and low word, allows the test/control (TC) flag bit of status register 0 (ST0) and the transition (TRN) register to keep their transition histories, and selects the larger word in the accumulator to be stored in data memory. The CSSU also accelerates Viterbi-type butterfly computation with optimized on-chip hardware.

program control

Program control is provided by several hardware and software mechanisms:

- The program controller decodes instructions, manages the pipeline, stores the status of operations, and decodes conditional operations. Some of the hardware elements included in the program controller are the program counter, the status and control register, the stack, and the address-generation logic.
- Some of the software mechanisms used for program control include branches, calls, conditional instructions, a repeat instruction, reset, and interrupts.

power-down modes

There are three power-down modes, activated by the IDLE1, IDLE2, and IDLE3 instructions. In these modes, the '54x devices enter a dormant state and dissipate considerably less power than in normal operation. The IDLE1 instruction is used to shut down the CPU. The IDLE2 instruction is used to shut down the CPU and on-chip peripherals. The IDLE3 instruction is used to shut down the '54x processor completely. This instruction stops the PLL circuitry as well as the CPU and peripherals.

bus structure

The '54x device architecture is built around eight major 16-bit buses:

- One program-read bus (PB), which carries the instruction code and immediate operands from program memory
- Two data-read buses (CB, DB) and one data-write bus (EB), which interconnect to various elements, such as the CPU, data-address generation logic, program-address generation logic, on-chip peripherals, and data memory
 - The CB and DB carry the operands read from data memory.
 - The EB carries the data to be written to memory.
- Four address buses (PAB, CAB, DAB, and EAB), which carry the addresses needed for instruction execution

The '54x devices have the capability to generate up to two data-memory addresses per cycle, which are stored into two auxiliary register arithmetic units (ARAU0 and ARAU1).

The PB can carry data operands stored in program space (for instance, a coefficient table) to the multiplier for multiply/accumulate operations or to a destination in data space for the data move instruction. This capability allows implementation of single-cycle three-operand instructions such as FIRS.

The '54x devices also have an on-chip bidirectional bus for accessing on-chip peripherals; this bus is connected to DB and EB through the bus exchanger in the CPU interface. Accesses using this bus can require more than two cycles for reads and writes depending on the peripheral's structure.

The '54x devices can have bus keepers connected to the data bus. Bus keepers ensure that the data bus does not float. When bus keepers are enabled, the data bus maintains its previous level. Setting bit 1 of the bank switching control register (BSCR) enables bus keepers and clearing bit 1 disables the bus keepers. A reset automatically disables the bus keepers.

TMS320C54x, TMS320LC54x, TMS320VC54x FIXED-POINT DIGITAL SIGNAL PROCESSORS

SPRS039C – FEBRUARY 1996 – REVISED DECEMBER 1999

bus structure (continued)

The '548 and '549 devices also have equivalent bus keepers connected to the address bus. The bus keepers ensure the address bus does not float when in high-impedance. For the '548 and '549 devices, the bus keepers are always enabled.

Table 2 summarizes the buses used by various types of accesses.

Table 2. Bus Usage for Accesses

| ACCESS TYPE | ADDRESS BUS | | | | PROGRAM BUS | DATA BUS | | |
|----------------------------|-------------|-------|-------|-----|-------------|----------|-------|----|
| | PAB | CAB | DAB | EAB | PB | CB | DB | EB |
| Program read | √ | | | | √ | | | |
| Program write | √ | | | | | | | √ |
| Data single read | | | √ | | | | √ | |
| Data dual read | | √ | √ | | | √ | √ | |
| Data long (32-bit) read | | √(hw) | √(lw) | | | √(hw) | √(lw) | |
| Data single write | | | | √ | | | | √ |
| Data read/data write | | | √ | √ | | | √ | √ |
| Dual read/coefficient read | √ | √ | √ | | √ | √ | √ | |
| Peripheral read | | | √ | | | | √ | |
| Peripheral write | | | | √ | | | | √ |

Legend:

hw = high 16-bit word

lw = low 16-bit word

memory

The total memory address range for the host of '54x devices is 192K 16-bit words. The '548 and '549 devices have 8M-word program memory. The memory space is divided into three specific memory segments: 64K-word program, 64K-word data, and 64K-word I/O. The program memory space contains the instructions to be executed as well as tables used in execution. The data memory space stores data used by the instructions. The I/O memory space interfaces to external memory-mapped peripherals and can also serve as extra data storage space.

The parallel nature of the architecture of these DSPs allows them to perform four concurrent memory operations in any given machine cycle: fetching an instruction, reading two operands, and writing an operand. The four parallel buses are the program-read bus (PB), the data-write bus (EB) and the two data-read buses (CB and DB). Each bus accesses different memory spaces for different aspects of the DSP's operation. Additionally, this architecture allows dual-operand reads, 32-bit-long word accesses, and a single read with a parallel store.

The '54x DSPs include on-chip memory to aid in system performance and integration.

on-chip ROM

The 'C541 and 'LC541 feature a 28K-word × 16-bit on-chip maskable ROM. 8K words of the 'C541 and 'LC541 ROM can be mapped into program and data memory space if the data ROM (DROM) bit in the processor mode status (PMST) register is set. This allows an instruction to use data stored in the ROM as an operand.

The 'LC545/'LC546 all feature a 48K-word × 16-bit on-chip maskable ROM. 16K words of the ROM on these devices can be mapped into program and data memory space if the DROM bit in the PMST register is set.

The 'C542/'LC542/'LC543/'LC548 all feature 2K-word × 16-bit on-chip ROM.

The 'LC549 and 'VC549 feature 16K-word × 16-bit on-chip ROM.

on-chip ROM (continued)

Customers can arrange to have the ROM of the '54x programmed with contents unique to any particular application.

on-chip dual-access RAM (DARAM)

The '541 devices have a 5K-word \times 16-bit on-chip DARAM (5 blocks of 1K-word each).

The '542 and '543 devices have a 10K-word \times 16-bit on-chip DARAM (5 blocks of 2K-word each).

The '545 and '546 devices have a 6K-word \times 16-bit on-chip DARAM (3 blocks of 2K-word each).

The '548 and '549 devices have a 8K-word \times 16-bit on-chip DARAM (4 blocks of 2K-word each).

Each of these RAM blocks can be accessed twice per machine cycle. This memory is intended primarily to store data values; however, it can be used to store program as well. At reset, the DARAM is mapped into data memory space. DARAM can be mapped into program/data memory space by setting the OVLY bit in the PMST register.

on-chip single-access RAM (SARAM)

The '548 and '549 devices have a 24K word \times 16 bit on-chip SARAM (three blocks of 8K words each).

Each of these SARAM blocks is a single-access memory. This memory is intended primarily to store data values; however, it can be used to store program as well. At reset, the SARAM is mapped into data memory space (2000h–7FFFh). SARAM can be mapped into program/data memory space by setting the OVLY bit in the PMST register.

on-chip memory security

The '54x devices have a maskable option to protect the contents of on-chip memories. When the related bit is set, no externally originating instruction can access the on-chip memory spaces.

program memory

The external program memory space on the '54x devices addresses up to 64K 16-bit words. Software can configure their memory cells to reside inside or outside of the program address map. When the cells are mapped into program space, the device automatically accesses them when their addresses are within bounds. When the program-address generation (PAGEN) logic generates an address outside its bounds, the device automatically generates an external access. The advantages of operating from on-chip memory are as follows:

- Higher performance because no wait states are required
- Lower cost than external memory
- Lower power than external memory

The advantage of operating from off-chip memory is the ability to access a larger address space.

program memory address map

The reset, interrupt, and trap vectors are addressed in program space. These vectors are soft — meaning that the processor, when taking the trap, loads the program counter (PC) with the trap address and executes the code at the vector location. Four words are reserved at each vector location to accommodate a delayed branch instruction, and either two 1-word instructions or one 2-word instruction, which allows branching to the appropriate interrupt service routine without the overhead.

At device reset, the reset, interrupt, and trap vectors are mapped to address FF80h in program space. However, these vectors can be remapped to the beginning of any 128-word page in program space after device reset. This is done by loading the interrupt vector pointer (IPTR) bits in the PMST register with the appropriate 128-word page boundary address. After loading IPTR, any user interrupt or trap vector is mapped to the new 128-word page. For example:

```
STM    #05800h,PMST    ;Remapped vectors to start at 5800h.
```

This example moves the interrupt vectors to program space at address 05800h. Any subsequent interrupt (except for a device reset) fetches its interrupt vector from that new location. For example, if, after loading the IPTR, an $\overline{\text{INT2}}$ occurs, the interrupt service routine vector is fetched from location 5848h in program space as opposed to location FFC8h. This feature facilitates moving the desired vectors out of the boot ROM and then removing the ROM from the memory map. Once the system code is booted into the system from the boot-loader code resident in ROM, the application reloads the IPTR with a value pointing to the new vectors. In the previous example, the STM instruction is used to modify the PMST. Note that the STM instruction modifies not only the IPTR but other status/control bits in the PMST register.

NOTE: The hardware reset ($\overline{\text{RS}}$) vector cannot be remapped, because the hardware reset loads the IPTR with 1s. Therefore, the reset vector is always fetched at location FF80h in program space. In addition, for the '54x, 128 words are reserved in the on-chip ROM for device-testing purposes. Application code written to be implemented in on-chip ROM must reserve these 128 words at addresses FF00h–FF7Fh in program space.

extended program memory ('548 and '549 only)

The '548 and '549 devices use a paged extended memory scheme in program space to allow access of up to 8M of program memory. This extended program memory is organized into 128 pages (0–127), each 64K in length. To implement the extended program memory scheme, the '548 and '549 device includes the following additional features:

- Seven additional address lines (for a total of 23)
- An extra memory-mapped register [program counter extension register (XPC)]

extended program memory ('548 and '549 only) (continued)

- Six new instructions for addressing extended program memory space:
 - FB[D] — Far branch
 - FBACC[D] — Far branch to the location specified by the value in accumulator A or accumulator B
 - FCALA[D] — Far call to the location specified by the value in accumulator A or accumulator B
 - FCALL[D] — Far call
 - FRET[D] — Far return
 - FRETE[D] — Far return with interrupts enabled
- Two '54x instructions are extended to use the 23 bits in the '548 and '549 devices:
 - READA — Read program memory addressed by accumulator A and store in data memory
 - WRITA — Write data to program memory addressed by accumulator A

For more information on these six new instructions and the two extended instructions, refer to the instruction set summary table in this data sheet and to the *TMS320C54x DSP Reference Set, Volume 2, Mnemonic Instruction Set*, literature number SPRU172. And for more information on extended program memory, refer to the *TMS320C54x DSP Reference Set, Volume 1, CPU and Peripherals*, literature number SPRU131.

data memory

The data memory space on the '54x device addresses contains up to 64K of 16-bit words. The 'devices automatically access the on-chip RAM when addressing within its bounds. When an address is generated outside the RAM bounds, the device automatically generates an external access.

The advantages of operating from on-chip memory are as follows:

- Higher performance because no wait states are required
- Higher performance because of better flow within the pipeline of the CALU
- Lower cost than external memory
- Lower power than external memory

The advantage of operating from off-chip memory is the ability to access a larger address space.

bootloader

A bootloader is available in the standard '54x on-chip ROM. This bootloader can be used to transfer user code from an external source to anywhere in the program memory at power up automatically. If $\overline{\text{MP}}/\overline{\text{MC}}$ of the device is sampled low during a hardware reset, execution begins at location FF80h of the on-chip ROM. This location contains a branch instruction to the start of the bootloader program. The standard '54x devices provide different ways to download the code to accommodate various system requirements:

- Parallel from 8-bit or 16-bit-wide EPROM
- Parallel from I/O space 8-bit or 16-bit mode
- Serial boot from serial ports 8-bit or 16-bit mode
- Host-port interface boot ('542, '545, '548, and '549 devices only)
- Warm boot

TMS320C54x, TMS320LC54x, TMS320VC54x FIXED-POINT DIGITAL SIGNAL PROCESSORS

SPRS039C – FEBRUARY 1996 – REVISED DECEMBER 1999

bootloader (continued)

The bootloader provided in the on-chip ROM of the '548 and '549 devices implements several enhanced features. These include the addition of BSP and TDM boot modes. To accommodate these new boot modes, the encoding of the boot-mode selection word has been modified.

For a detailed description of bootloader functionality, refer to the *TMS320C54x DSP Reference Set, Volume 4: Applications Guide* (literature number SPRU173). For a detailed description of the enhanced bootloader functionality, refer to the *TMS320x548/'549 Bootloader Technical Reference*.

on-chip peripherals

All the '54x devices have the same CPU structure; however, they have different on-chip peripherals connected to their CPUs. The on-chip peripheral options provided are:

- Software-programmable wait-state generator
- Programmable bank switching
- Parallel I/O ports
- Serial ports (standard, TDM, and BSP)
- A hardware timer
- A clock generator [with a multiple phase-locked loop (PLL) on '549 devices]

software-programmable wait-state generators

Software-programmable wait-state generators can be used to extend external bus cycles up to seven machine cycles to interface with slower off-chip memory and I/O devices. The software wait-state generators are incorporated without any external hardware. For off-chip memory access, a number of wait states can be specified for every 32K-word block of program and data memory space, and for one 64K-word block of I/O space within the software wait-state (SWWSR) register.

programmable bank-switching

Programmable bank-switching can be used to insert one cycle automatically when crossing memory-bank boundaries inside program memory or data memory space. One cycle can also be inserted when crossing from program-memory space to data-memory space ('54x) or one program memory page to another program memory page ('548 and '549 only). This extra cycle allows memory devices to release the bus before other devices start driving the bus; thereby avoiding bus contention. The size of memory bank for the bank-switching is defined by the bank-switching control register (BSCR).

parallel I/O ports

Each '54x device has a total of 64K I/O ports. These ports can be addressed by the PORTR instruction or the PORTW instruction. The \overline{IS} signal indicates a read/write operation through an I/O port. The devices can interface easily with external devices through the I/O ports while requiring minimal off-chip address-decoding circuits.

host-port interface ('542, '545, '548, and '549 only)

The host-port interface (HPI) is an 8-bit parallel port used to interface a host processor to the DSP device. Information is exchanged between the DSP device and the host processor through on-chip memory that is accessible by both the host and the DSP device. The DSP devices have access to the HPI control (HPIC) register and the host can address the HPI memory through the HPI address register (HPIA). HPI memory is a 2K-word DARAM block that resides at 1000h to 17FFh in data memory and can also be used as general-purpose on-chip data or program DARAM.

host-port interface ('542, '545, '548, and '549 only) (continued)

Data transfers of 16-bit words occur as two consecutive bytes with a dedicated pin (HBIL) indicating whether the high or low byte is being transmitted. Two control pins, HCNTL1 and HCNTL0, control host access to the HPIA, HPI data (with an optional automatic address increment), or the HPIC. The host can interrupt the DSP device by writing to HPIC. The DSP device can interrupt the host with a dedicated $\overline{\text{HINT}}$ pin that the host can acknowledge and clear.

The HPI has two modes of operation, shared-access mode (SAM) and host-only mode (HOM). In SAM, the normal mode of operation, both the DSP device and the host can access HPI memory. In this mode, asynchronous host accesses are resynchronized internally and, in case of conflict, the host has access priority and the DSP device waits one cycle. The HOM capability allows the host to access HPI memory while the DSP device is in IDLE2 (all internal clocks stopped) or in reset mode. The host can therefore access the HPI RAM while the DSP device is in its optimal configuration in terms of power consumption.

The HPI control register has two data strobes, $\overline{\text{HDS1}}$ and $\overline{\text{HDS2}}$, a read/write strobe $\text{HR}/\overline{\text{W}}$, and an address strobe $\overline{\text{HAS}}$, to enable a glueless interface to a variety of industry-standard host devices. The HPI is interfaced easily to hosts with multiplexed address/data bus, separate address and data buses, one data strobe and a read/write strobe, or two separate strobes for read and write.

The HPI supports high-speed back-to-back accesses.

- In the SAM, the HPI can handle one byte every five DSP device periods—that is, 64 MBps with a 40-MIPS DSP, or 160 MBps with a 100-MIPS DSP. The HPI is designed so that the host can take advantage of this high bandwidth and run at frequencies up to $(f \times n) \div 5$, where n is the number of host cycles for an external access and f is the DSP device frequency.
- In HOM, the HPI supports high-speed back-to-back host accesses at 1 byte every 50 ns—that is, 160 MBps with a -40 or faster DSP.

serial ports

The '54x devices provide high-speed full-duplex serial ports that allow direct interface to other '54x devices, codecs, and other devices in a system. There is a standard serial port, a time-division-multiplexed (TDM) serial port, and a buffered serial port (BSP). The '549 devices provides a misalignment detection feature to that allows the device to detect when a word or words are lost in the serial data line.

The general-purpose serial port utilizes two memory-mapped registers for data transfer: the data-transmit register (DXR) and the data-receive register (DRR). Both of these registers can be accessed in the same manner as any other memory location. The transmit and receive sections of the serial port each have associated clocks, frame-synchronization pulses, and serial-shift registers; and serial data can be transferred either in bytes or in 16-bit words. Serial port receive and transmit operations can generate their own maskable transmit and receive interrupts (XINT and RINT), allowing serial-port transfers to be managed through software. The '54x serial ports are double-buffered and fully static.

The TDM port allows the device to communicate through time-division multiplexing with up to seven other '54x devices with TDM ports. Time-division multiplexing is the division of time intervals into a number of subintervals with each subinterval representing a prespecified communications channel. The TDM port serially transmits 16-bit words on a single data line (TDAT) and destination addresses on a single address line (TADD). Each device can transmit data on a single channel and receive data from one or more of the eight channels, providing a simple and efficient interface for multiprocessing applications. A frame synchronization pulse occurs once every 128 clock cycles, corresponding to the transmission of one 16-bit word on each of the eight channels. Like the general-purpose serial port, the TDM port is double-buffered on both input and output data.

The buffered serial port (BSP) consists of a full-duplex double-buffered serial-port interface and an auto-buffering unit (ABU). The serial port block of the BSP is an enhanced version of the standard serial port. The ABU allows the serial port to read/write directly to the '54x internal memory using a dedicated bus independent of the CPU. This results in minimal overhead for serial port transactions and faster data rates.

TMS320C54x, TMS320LC54x, TMS320VC54x FIXED-POINT DIGITAL SIGNAL PROCESSORS

SPRS039C – FEBRUARY 1996 – REVISED DECEMBER 1999

serial ports (continued)

When auto-buffering capability is disabled (standard mode), serial port transfers are performed under software control through interrupts. In this mode, the ABU is transparent and the word-based interrupts (WXINT and WRINT) provided by the serial port are sent to the CPU as transmit interrupt (XINT) and receive interrupt (RINT). When auto buffering is enabled, word transfers are done directly between the serial port and the '54x internal memory using ABU-embedded address generators.

The ABU has its own set of circular-addressing registers with corresponding address-generation units. Memory for the buffers resides in 2K words of the '54x internal memory. The length and starting addresses of the buffers are user-programmable. A buffer-empty/buffer-full interrupt can be posted to the CPU. Buffering is easily halted by an auto-disabling capability. Auto-buffering capability can be enabled separately for transmit and receive sections. When auto buffering is disabled, operation is similar to that of the general-purpose serial port.

The BSP allows transfer of 8-, 10-, 12-, or 16-bit data packets. In burst mode, data packets are directed by a frame synchronization pulse for every packet. In continuous mode, the frame synchronization pulse occurs when the data transmission is initiated and no further pulses occur. The frame and clock strobes are frequency- and polarity-programmable. The BSP is fully static and operates at arbitrarily low clock frequencies. The maximum operating frequency for '54x devices up to 50 MIPs is CLKOUT. For higher-speed '54x devices, the maximum operating frequency is 50 MBps at 20 ns.

buffer misalignment (BMINT) interrupt ('549 only)

The BMINT interrupt is generated when a frame sync occurs and the ABU transmit or receive buffer pointer is not at the top of the buffer address. This is useful for detecting several potential error conditions on the serial interface, including extraneous and missed clocks and frame sync pulses. A BMINT interrupt, therefore, indicates that one or more words may have been lost on the serial interface.

BMINT is useful for detecting buffer misalignment only when the buffer pointer(s) are initially loaded with the top of buffer address, and a frame of data contains the same number of words as the buffer length. These are the only conditions under which a frame sync occurring at a buffer address, other than the top of buffer, constitute an error condition. In cases where these conditions are met, a frame sync always occurs when the buffer pointer is at the top of buffer address, if the interface is functioning properly.

If BMINT is enabled under conditions other than those stated above, interrupts may be generated under circumstances other than actual buffer misalignment. In these cases, BMINT should generally be masked in the IMR register so that the processor will ignore this interrupt.

BMINT is available when operating auto-buffering mode with continuous transfers, the FIG bit cleared to 0, and external serial clocks or frames.

The BSP0 and BSP1 BMINT bits in the IMR and IFR registers are bits 12 and 13, respectively, (bit 15 is the MSB), and their interrupt vector locations are 070h and 074h, respectively.

serial ports (continued)

Table 3 provides a comparison of the serial ports available in the '54x devices.

Table 3. Serial Port Configurations for the '54x

| DEVICE | NO. OF STANDARD SERIAL PORTS | NO. OF BSPs (BSP ADDRESS RANGES) | NO. OF TDM SERIAL PORTS |
|-----------------------------|------------------------------|----------------------------------|-------------------------|
| TMS320C541 TMS320LC541 | 2 | – | – |
| TMS320C542 TMS320LC542 | – | 1 (0800h–0FFFh) | 1 |
| TMS320LC543 | – | 1 (0800h–0FFFh) | 1 |
| TMS320LC545 TMS320LC545A | 1 | 1 (0800h–0FFFh) | – |
| TMS320LC546 TMS320LC546A | 1 | 1 (0800h–0FFFh) | – |
| TMS320LC548 | – | 2 (0800h–0FFFh and 1800h–1FFFh) | 1 |
| TMS320LC549 TMS320VC549 | – | 2 (0800h–0FFFh and 1800h–1FFFh) | 1 |

hardware timer

The '54x devices feature a 16-bit timing circuit with a four-bit prescaler. The timer counter is decremented by one at every CLKOUT cycle. Each time the counter decrements to zero, a timer interrupt is generated. The timer can be stopped, restarted, reset, or disabled by specific status bits.

clock generator

The clock generator provides clocks to the '54x device, and consists of an internal oscillator and a phase-locked loop (PLL) circuit. The clock generator requires a reference clock input, which can be provided by using a crystal resonator with the internal oscillator, or from an external clock source. The reference clock input is then either divided by two (or by four on the '545A, '546A, '548, and '549) to generate clocks for the '54x device, or the PLL circuit can be used to generate the device clock by multiplying the reference clock frequency by a scale factor, allowing use of a clock source with a lower frequency than that of the CPU.

The PLL is an adaptive circuit that, once synchronized, locks onto and tracks an input clock signal. When the PLL is initially started, it enters a transitional mode during which the PLL acquires lock with the input signal. Once the PLL is locked, it continues to track and maintain synchronization with the input signal. Then, other internal clock circuitry allows the synthesis of new clock frequencies for use as master clock for the '54x device.

Two types of PLL are available: a hardware-programmable PLL and a software-programmable PLL. All '54x devices have the hardware-programmable PLL except the '545A, '546A, '548, and '549, which have the software-programmable PLL. On the hardware-programmable PLL, an external delay must be provided before the device is released from reset in order for the PLL to achieve lock. With the software-programmable PLL, a lock timer is provided to implement this delay automatically. Note that both the hardware- and the software-programmable PLLs require the device to be reset after power up to begin functioning properly.

hardware-programmable PLL

The '54x can use either the internal oscillator or an external frequency source for an input clock. The clock generation mode is determined by the CLKMD1, CLKMD2 and CLKMD3 clock mode pins except on the '545A, the '546A, the '548, and the '549 (see software-programmable PLL description below). Table 4 outlines the selection of the clock mode by these pins. Note that both the hardware- and the software-programmable PLLs require the device to be reset after power up to begin functioning properly.

SPRS039C – FEBRUARY 1996 – REVISED DECEMBER 1999

hardware-programmable PLL (continued)

Table 4. Clock Mode Configurations

| MODE-SELECT PINS | | | CLOCK MODE | |
|------------------|--------|--------|--|--|
| CLKMD1 | CLKMD2 | CLKMD3 | OPTION 1† | OPTION 2† |
| 0 | 0 | 0 | PLL × 3 with external source | PLL × 5 with external source |
| 1 | 1 | 0 | PLL × 2 with external source | PLL × 4 with external source |
| 1 | 0 | 0 | PLL × 3, internal oscillator enabled | PLL × 5, internal oscillator enabled |
| 0 | 1 | 0 | PLL × 1.5 with external source | PLL × 4.5 with external source |
| 0 | 0 | 1 | Divide-by-two with external source | Divide-by-two with external source |
| 0 | 1 | 1 | Stop mode‡ | Stop mode‡ |
| 1 | 0 | 1 | PLL × 1 with external source | PLL × 1 with external source |
| 1 | 1 | 1 | Divide-by-two, internal oscillator enabled | Divide-by-two, internal oscillator enabled |

† Option: Option 1 or option 2 is selected when ordering the device.

‡ Stop mode: The function of the stop mode is equivalent to that of the power-down mode of IDLE3; however, the IDLE3 instruction is recommended rather than stop mode to realize full power saving, since IDLE3 stops clocks synchronously and can be exited with an interrupt.

software-programmable PLL ('545A, '546A, '548, and '549)

The software-programmable PLL features a high level of flexibility, and includes a clock scaler that provides various clock multiplier ratios, capability to directly enable and disable the PLL, and a PLL lock timer that can be used to delay switching to PLL clocking mode of the device until lock is achieved.

Devices that have a built-in software-programmable PLL can be configured in one of two clock modes:

- PLL mode. The input clock (X2/CLKIN) is multiplied by 1 of 31 possible ratios. These ratios are achieved using the PLL circuitry.
- DIV (divider) mode. The input clock is divided by 2 or 4. Note that when DIV mode is used, the PLL can be completely disabled in order to minimize power dissipation.

The software-programmable PLL is controlled using the 16-bit memory-mapped (address 0058h) clock mode register (CLKMD). The CLKMD register is used to define the clock configuration of the PLL clock module. The CLKMD register fields are shown in Figure 7 and described below. Note that upon reset, the CLKMD register is initialized with a predetermined value dependent only upon the state of the CLKMD1 – CLKMD3 pins (see Table 6).

| Bit # | 15–12 | 11 | 10–3 | 2 | 1 | 0 |
|-------|--------|--------|----------|-----------|---------|-----------|
| | PLLMUL | PLLDIV | PLLCOUNT | PLLON/OFF | PLLNDIV | PLLSTATUS |
| | R/W† | R/W† | R/W† | R/W† | R/W | R |

R = read, W = write

† When in DIV mode (PLLSTATUS is low), PLLMUL, PLLDIV, PLLCOUNT, and PLLON/OFF are don't cares, and their contents are indeterminate.

Figure 7. Clock Mode Control Register (CLKMD)

software-programmable PLL ('545A, '546A, '548, and '549) (continued)

Bits 15–12 PLLMUL. PLL multiplier. Defines the frequency multiplier in conjunction with PLLDIV and PLLNDIV, as shown in Table 5.

Bit 11 PLLDIV. PLL divider. Defines the frequency multiplier in conjunction with PLLMUL and PLLNDIV, as shown in Table 5.

0 = an integer multiply factor is used.

1 = a non-integer multiply factor is used.

Bits 10–3 PLLCOUNT. PLL counter value. Specifies the number of input clock cycles (in increments of 16 cycles) for the PLL lock timer to count before the PLL begins clocking the processor after the PLL is started. The PLL counter is a down-counter, which is driven by the input clock divided by 16; therefore, for every 16 input clocks, the PLL counter decrements by one.

The PLL counter can be used to ensure that the processor is not clocked until the PLL is locked, so that only valid clock signals are sent to the device.

Bit 2 PLLON/OFF. PLL on/off. Enables or disables the PLL part of the clock generator in conjunction with the PLLNDIV bit. Note that PLLON/OFF and PLLNDIV can both force the PLL to run; when PLLON/OFF is high, the PLL runs independently of the state of PLLNDIV.

| PLLON/OFF | PLLNDIV | PLL STATE |
|-----------|---------|-----------|
| 0 | 0 | Off |
| 1 | 0 | On |
| 0 | 1 | On |
| 1 | 1 | On |

Bit 1 PLLNDIV. PLL clock generator select. Determines whether the clock generator works in PLL mode or in divider (DIV) mode, thereby defining the frequency multiplier in conjunction with PLLMUL and PLLDIV.

0 = Divider mode is used

1 = PLL mode is used

Bit 0 PLLSTATUS. PLL status. Indicates the mode in which the clock generator is operating.

0 = DIV mode

1 = PLL mode

SPRS039C – FEBRUARY 1996 – REVISED DECEMBER 1999

software-programmable PLL ('545A, '546A, '548, and '549) (continued)

Immediately following reset, the clock mode is determined by the values of the three external pins: CLKMD1, CLKMD2, and CLKMD3. The modes corresponding to the CLKMD pins are shown in Table 6.

Table 6. Clock Mode Settings at Reset

| CLKMD1 | CLKMD2 | CLKMD3 | CLKMD REGISTER RESET VALUE | CLOCK MODE |
|--------|--------|--------|-------------------------------|---|
| 0 | 0 | 0 | 0000h | Divide-by-two, with external source |
| 0 | 0 | 1 | 1000h | Divide-by-two, with external source |
| 0 | 1 | 0 | 2000h | Divide-by-two, with external source |
| 1 | 0 | 0 | 4000h | Divide-by-two, internal oscillator enabled |
| 1 | 1 | 0 | 6000h | Divide-by-two, with external source |
| 1 | 1 | 1 | 7000h | Divide-by-two, internal oscillator enabled [†] |
| 1 | 0 | 1 | 0007h | PLL × 1 with external source |
| 0 | 1 | 1 | — | Stop mode |

[†] Reserved mode ('549 only). Do not use in normal operation.

Following reset, the software-programmable PLL can be programmed to any configuration desired, as described above. Note that when the PLL × 1 with external source option (CLKMD[1–3]=101) is selected during reset, the internal PLL lock-count timer is not active; therefore, the system must delay releasing reset in order to allow for the PLL lock-time delay. Also, note that both the hardware- and the software-programmable PLLs require the device to be reset after power up to begin functioning properly.

programming considerations when using the software-programmable PLL

The software-programmable PLL offers many different options in startup configurations, operating modes, and power-saving features. Programming considerations and several software examples are presented here to illustrate the proper use of the software-programmable PLL at start-up, when switching between different clocking modes, and before and after IDLE1/IDLE2/IDLE3 instruction execution.

use of the PLLCOUNT programmable lock timer

During the lockup period, the PLL should not be used to clock the '54x. The PLLCOUNT programmable lock timer provides a convenient method of automatically delaying clocking of the device by the PLL until lock is achieved.

The PLL lock timer is a counter, loaded from the PLLCOUNT field in the CLKMD register, that decrements from its preset value to 0. The timer can be preset to any value from 0 to 255, and its input clock is CLKIN divided by 16. The resulting lockup delay can therefore be set from 0 to 255 × 16 CLKIN cycles.

The lock timer is activated when the clock generator operating mode is switched from DIV to PLL (see the section describing switching from DIV mode to PLL mode). During the lockup period, the clock generator continues to operate in DIV mode; after the PLL lock timer has decremented to zero, the PLL begins clocking the '54x.

Accordingly, the value loaded into PLLCOUNT is chosen based on the following relationship:

$$\text{PLLCOUNT} > \text{Lockup Time} / (16 \times t_{\text{CLKIN}})$$

where t_{CLKIN} is the input reference clock period and lockup time is the required PLL lockup time as shown in Figure 8.

use of the PLLCOUNT programmable lock timer (continued)

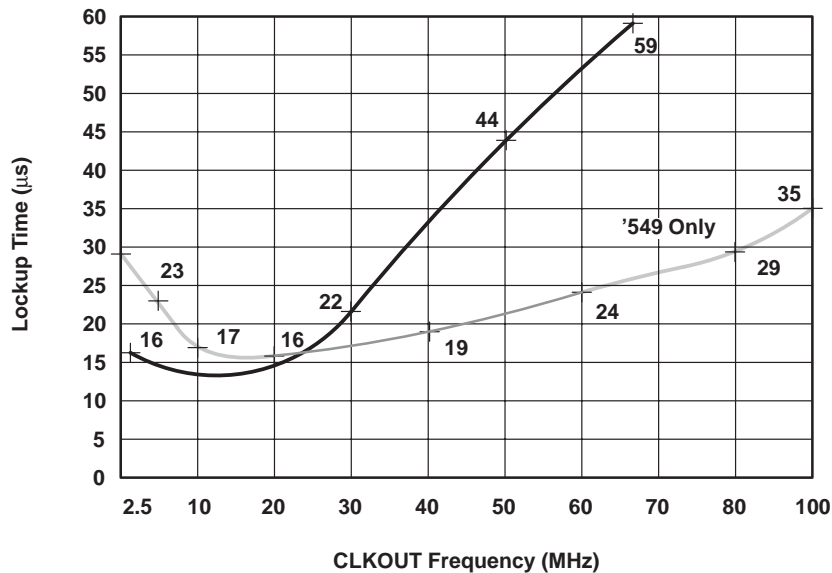

Figure 8. PLL Lockup Time Versus CLKOUT Frequency

switching from DIV mode to PLL mode

Several circumstances may require switching from DIV mode to PLL mode; however, note that if the PLL is not locked when switching from DIV mode to PLL mode, the PLL lockup time delay must be observed before the mode switch occurs to ensure that only proper clock signals are sent to the device. It is, therefore, important to know whether or not the PLL is locked when switching operating modes.

The PLL is unlocked on power-up, after changing the PLLMUL or PLLDIV values, after turning off the PLL (PLLON/OFF = 0), or after loss of input reference clock. Once locked, the PLL remains locked even in DIV mode as long as the PLL had been previously locked and has not been turned off (PLLON/OFF stays 1), and the PLLMUL and PLLDIV values have not been changed since the PLL was locked.

Switching from DIV mode to PLL mode (setting PLLNDIV to 1) activates the PLLCOUNT programmable lock timer (when PLLCOUNT is preloaded with a non-zero value), and this can be used to provide a convenient method for implementing the lockup time delay. The PLLCOUNT lock timer feature should be used in the situations described above, where the PLL is unlocked unless a reset delay is used to implement the lockup delay, or the PLL is not used.

Switching from DIV mode to PLL mode is accomplished by loading the CLKMD register. The following procedure describes switching from DIV mode to PLL mode when the PLL is not locked. When performing this mode switch with the PLL already locked, the effect is the same as when switching from PLL to DIV mode, but in the reverse order. In this case, the delays of when the new clock mode takes effect are the same.

When switching from DIV to PLL mode with the PLL unlocked, or when the mode change will result in unlocked operation, the PLLMUL[3–0], PLLDIV, and PLLNDIV bits are set to select the desired frequency multiplier as described in Table 5, and the PLLCOUNT[7–0] bits are set to select the required lockup time delay. Note that PLLMUL, PLLDIV, PLLCOUNT, and PLLON/OFF can only be modified when in DIV mode.

TMS320C54x, TMS320LC54x, TMS320VC54x FIXED-POINT DIGITAL SIGNAL PROCESSORS

SPRS039C – FEBRUARY 1996 – REVISED DECEMBER 1999

switching from DIV mode to PLL mode (continued)

Once the PLLNDIV bit is set, the PLLCOUNT timer begins being decremented from its preset value. When the PLLCOUNT timer reaches zero, the switch to PLL mode takes effect after six CLKIN cycles plus 3.5 PLL cycles (CLKOUT frequency). When the switch to PLL mode is completed, the PLLSTATUS bit in the CLKMD register is read as 1. Note that during the PLL lockup period, the '54x continues operating in DIV mode.

The following software example shows an instruction that can be used to switch from DIV mode to PLL $\times 3$, with a CLKIN frequency of 13 MHz and PLLCOUNT = 41 (decimal).

```
STM      #0010000101001111b, CLKMD
```

switching clock mode from PLL to DIV

When switching from PLL mode to DIV mode, the PLLCOUNT delay does not occur, and the switch between the two modes takes place after a short transition delay.

The switch from PLL mode to DIV mode is also accomplished by loading the CLKMD register. The PLLNDIV bit is set to 0, selecting DIV mode, and the PLLMUL bits are set to select the desired frequency multiplier as shown in Table 5.

The switch to DIV mode takes effect in 6 CLKIN cycles plus 3.5 PLL cycles (CLKOUT frequency) for all PLLMUL values except 1111b. With a PLLMUL value of 1111b, the switch to DIV mode takes effect in 12 CLKIN cycles plus 3.5 PLL cycles (CLKOUT frequency). When the switch to DIV mode is completed, the PLLSTATUS bit in the CLKMD register is read as 0.

The following software example shows a code sequence that can be used to switch from PLL $\times 3$ to divide-by-two mode. Note that the PLLSTATUS bit is polled to determine when the switch to DIV mode has taken effect, and then the STM instruction is used to turn off the PLL at this point.

```
TstStatu:  STM      #0b, CLKMD                ;switch to DIV mode
            LDM      CLKMD, A
            AND      #01b, A                  ;poll STATUS bit
            BC       TstStatu, ANEQ
            STM      #0b, CLKMD                ;reset PLLON_OFF when STATUS
                                                ;is DIV mode
```

switching mode from one PLL multiplier to another

When switching from one PLL multiplier ratio to another is required, the clock generator must be switched from PLL mode to DIV mode before selecting the new multiplier ratio; switching directly from one PLL multiplier ratio to another is not supported.

In order to switch from one PLL multiplier ratio to another, the following steps must be followed:

1. Set the PLLNDIV bit to 0, selecting DIV mode.
2. Poll the PLLSTATUS bit until a 0 is obtained, indicating that DIV mode is enabled and that PLLMUL, PLLDIV, and PLLCOUNT can be updated.
3. Modify the CLKMD register to set the PLLMUL[3–0], PLLDIV, and PLLNDIV bits to the desired frequency multiplier as defined in Table 5, and the PLLCOUNT[7–0] bits to the required lock-up time.

When the PLLNDIV bit is set to one in step three, the PLLCOUNT timer begins decrementing from its preset value. Once the PLLCOUNT timer reaches zero, the new PLL mode takes effect after six CLKIN cycles plus 3.5 PLL cycles (CLKOUT frequency).

switching mode from one PLL multiplier to another (continued)

Also, note that a direct switch between divide-by-two mode and divide-by-four mode is not possible. To switch between these two modes, the clock generator must first be set to PLL mode with an integer-only (non-fractional) multiplier ratio, and then set back to DIV mode in the desired divider configuration (see previous sections for details on switching between DIV and PLL modes).

The following software example shows a code sequence that can be used to switch clock mode from PLL \times X to PLL \times 1.

```
TstStatu:  STM      #0b, CLKMD           ;switch to DIV mode
           LDM      CLKMD, A
           AND      #01b, A             ;poll STATUS bit
           BC       TstStatu, ANEQ
           STM      #0000001111101111b, CLKMD ;switch to PLL  $\times$  1 mode
```

programmable clock generator operation immediately following reset

Immediately following reset, the operating mode of the clock generator is determined only on the basis of the CLKMD1/2/3 pin state as described in Table 6. All but two of these operating modes are 'divide-by-two with external source'. Switching from divide-by-two to a PLL mode can easily be accomplished by changing the CLKMD register contents. Note that if use of the internal oscillator is desired, either the 100 or the 111 state of the CLKMD1–CLKMD3 pins must be selected at reset (as shown in Table 6) since the internal oscillator cannot be programmed through software.

The following software example shows an instruction that can be used to switch from divide-by-two mode to the PLL \times 3 mode.

```
STM      #0010000101001111b, CLKMD
```

considerations when using IDLE1/IDLE2/IDLE3

When using one of the IDLE instructions to reduce power requirements, proper management of the PLL is important. The clock generator consumes the least power when operating in DIV mode with the PLL disabled. Therefore, if power dissipation is a significant consideration, it is desirable to switch from PLL to DIV mode, and disable the PLL, before executing the IDLE1/IDLE2/IDLE3 instructions. This is accomplished as explained above in the section describing switching clock mode from PLL to DIV. After waking up from IDLE1/IDLE2/IDLE3, the clock generator can be reprogrammed to PLL mode as explained above in the section describing switching clock mode from DIV to PLL.

Note that when the PLL is stopped during an IDLE state, and the '54x device is restarted and the clock generator is switched back to PLL mode, the PLL lockup delay occurs in the same manner as in a normal device startup. Therefore, in this case, the lockup delay must also be accounted for, either externally or by using the PLL lockup counter timer.

The following software example illustrates a code sequence that switches the clock generator from PLL \times 3 mode to divide-by-two mode, turns off the PLL, and enters IDLE3. After waking up from IDLE3, the clock generator is switched back from DIV mode to PLL \times 3 mode using a single STM instruction, with a PLLCOUNT of 64 (decimal) used for the lock timer value.

considerations when using IDLE1/IDLE2/IDLE3 (continued)

```
TstStatu:  STM    #0b, CLKMD           ;switch to DIV mode
           LDM    CLKMD, A
           AND    #01b, A              ;poll STATUS bit
           BC     TstStatu, ANEQ
           STM    #0b, CLKMD           ;reset PLLON_OFF when STATUS
                                           ;is DIV mode

IDLE3
```

(After IDLE3 wake-up – switch the PLL from DIV mode to PLL × 3 mode)

```
STM    #0010001000000111b, CLKMD    ;PLLCOUNT = 64 (decimal)
```

PLL considerations when using the bootloader

The ROM on the '545A and '546A contains a bootloader program that can be used to load programs into RAM for execution following reset. When using this bootloader with the software-programmable PLL, several considerations are important for proper system operation.

On the '545A and '546A, for compatibility, the bootloader configures the PLL to the same mode as would have resulted if the same CLKMD1–3 input bits had been provided to the option-1 or option-2 hardware-programmable PLL (see Table 4), according to whether the '545A or '546A is an option-1 or option-2 device. Once the bootloader program has finished executing, and control is transferred to the user's program, the PLL can be reprogrammed to any desired configuration.

memory-mapped registers

Most '54x devices have 26 (except '548 and '549 have 27) memory-mapped CPU registers, which are mapped into data memory located at addresses 0h to 1Fh. Each of these devices also has a set of memory-mapped registers associated with peripherals. Table 7 gives a list of CPU memory-mapped registers (MMR) common to all '54x devices. Table 8 shows additional peripheral MMRs associated with the '541 devices, Table 9 shows those associated with the '545/'546 devices, Table 10 shows those associated with the '542/'543 devices, and Table 11 shows those associated with the '548/'549 devices.

SPRS039C – FEBRUARY 1996 – REVISED DECEMBER 1999

status registers (ST0, ST1)

The status registers, ST0 and ST1, contain the status of the various conditions and modes for the '54x devices. ST0 contains the flags (OV, C, and TC) produced by arithmetic operations and bit manipulations in addition to the data page pointer (DP) and the auxiliary register pointer (ARP) fields. ST1 contains the various modes and instructions that the processor operates on and executes.

accumulators (AL, AH, AG, and BL, BH, BG)

The '54x devices have two 40-bit accumulators: accumulator A and accumulator B. Each accumulator is memory-mapped and partitioned into accumulator low-word (AL, BL), accumulator high-word (AH, BH), and accumulator guard bits (AG, BG).

auxiliary registers (AR0–AR7)

The eight 16-bit auxiliary registers (AR0–AR7) can be accessed by the CALU and modified by the auxiliary register arithmetic units (ARAUs). The primary function of the auxiliary registers is generating 16-bit addresses for data space. However, these registers also can act as general-purpose registers or counters.

temporary register (TREG)

The TREG is used to hold one of the multiplicands for multiply and multiply/accumulate instructions. It can hold a dynamic (execution-time programmable) shift count for instructions with shift operation such as ADD, LD, and SUB instructions. It also can hold a dynamic bit address for the BITT instruction. The EXP instruction stores the exponent value computed into the TREG, while the NORM instruction uses the TREG value to normalize the number. For ACS operation of Viterbi decoding, TREG holds branch metrics used by the DADST and DSADT instructions.

transition register (TRN)

The TRN is a 16-bit register that is used to hold the transition decision for the path to new metrics to perform the Viterbi algorithm. The CMPS (compare, select, max, and store) instruction updates the contents of the TRN based on the comparison between the accumulator high word and the accumulator low word.

stack-pointer register (SP)

The SP is a 16-bit register that contains the address at the top of the system. The SP always points to the last element pushed onto the stack. The stack is manipulated by interrupts, traps, calls, returns, and the PUSH, PSHM, POPD, and POPM instructions. Pushes and pops of the stack predecrement and postincrement, respectively, all 16 bits of the SP.

circular-buffer-size register (BK)

The 16-bit BK is used by the ARAUs in circular addressing to specify the data block size.

block repeat registers (BRC, RSA, REA)

The block-repeat counter (BRC) is a 16-bit register used to specify the number of times a block of code is to be repeated when performing a block repeat. The block-repeat start address (RSA) is a 16-bit register containing the starting address of the block of program memory to be repeated when operating in the repeat mode. The 16-bit block repeat-end address (REA) contains the ending address if the block of program memory is to be repeated when operating in the repeat mode.

interrupt registers (IMR, IFR)

The interrupt-mask register (IMR) is used to mask off specific interrupts individually at required times. The interrupt-flag register (IFR) indicates the current status of the interrupts.

processor-mode status register (PMST)

The processor-mode status register (PMST) controls memory configurations of the '54x devices.

interrupts

Vector-relative locations and priorities for all internal and external interrupts are shown in Table 12.

Table 12. '54x Interrupt Locations and Priorities

| NAME | LOCATION | | PRIORITY | FUNCTION |

development support

Texas Instruments offers an extensive line of development tools for the '54x generation of DSPs, including tools to evaluate the performance of the processors, generate code, develop algorithm implementations, and fully integrate and debug software and hardware modules.

The following products support development of '54x-based applications:

Software Development Tools:

Assembler/Linker
Simulator
Optimizing ANSI C compiler
Application algorithms
C/Assembly debugger and code profiler

Hardware Development Tools:

Extended development system (XDS™) emulator (supports '54x multiprocessor system debug)
'54x EVM (Evaluation Module)
'54x DSK (DSP Starter Kit)

The *TMS320 Family Development Support Reference Guide* (SPRU011) contains information about development support products for all TMS320 family member devices, including documentation. Refer to this document for further information about TMS320 documentation or any other TMS320 support products from Texas Instruments. There is an additional document, the *TMS320 Third Party Support Reference Guide* (SPRU052), which contains information about TMS320-related products from other companies in the industry. To receive copies of TMS320 literature, contact the Literature Response Center at 800/477-8924.

See Table 14 for complete listings of development support tools for the '54x. For information on pricing and availability, contact the nearest TI field sales office or authorized distributor.

SPRS039C – FEBRUARY 1996 – REVISED DECEMBER 1999

device and development support tool nomenclature

To designate the stages in the product development cycle, TI assigns prefixes to the part numbers of all TMS320 devices and support tools. Each TMS320 member has one of three prefixes: TMX, TMP, or TMS. Texas Instruments recommends two of three possible prefix designators for its support tools: TMDX and TMDS. These prefixes represent evolutionary stages of product development from engineering prototypes (TMX/TMDX) through fully qualified production devices/tools (TMS/TMDS). This development flow is defined below.

Device development evolutionary flow:

| | |
|------------|--|
| TMX | Experimental device that is not necessarily representative of the final device's electrical specifications |
| TMP | Final silicon die that conforms to the device's electrical specifications but has not completed quality and reliability verification |
| TMS | Fully-qualified production device |

Support tool development evolutionary flow:

| | |
|-------------|--|
| TMDX | Development support product that has not yet completed Texas Instruments internal qualification testing. |
| TMDS | Fully qualified development support product |

TMX and TMP devices and TMDX development support tools are shipped against the following disclaimer:

"Developmental product is intended for internal evaluation purposes."

TMS devices and TMDS development support tools have been characterized fully, and the quality and reliability of the device has been demonstrated fully. TI's standard warranty applies.

Predictions show that prototype devices (TMX or TMP) have a greater failure rate than the standard production devices. Texas Instruments recommends that these devices not be used in any production system because their expected end-use failure rate still is undefined. Only qualified production devices are to be used.

TI device nomenclature also includes a suffix with the device family name. This suffix indicates the package type (for example, PZ, PGE, PBK, or GGU) and temperature range (for example, L). Figure 10 provides a legend for reading the complete device name for any TMS320 family member.

documentation support

Extensive documentation supports all TMS320 family generations of devices from product announcement through applications development. The types of documentation available include: data sheets, such as this document, with design specifications; complete user's guides for all devices; development support tools; and hardware and software applications.

The four-volume *TMS320C54x DSP Reference Set* (literature number SPRU210) consists of:

- *Volume 1: CPU and Peripherals* (literature number SPRU131)
- *Volume 2: Mnemonic Instruction Set* (literature number SPRU172)
- *Volume 3: Algebraic Instruction Set* (literature number SPRU179)
- *Volume 4: Applications Guide* (literature number SPRU173)

The reference set describes in detail the '54x TMS320 products currently available and the hardware and software applications, including algorithms, for fixed-point TMS320 devices.

For general background information on DSPs and TI devices, see the three-volume publication *Digital Signal Processing Applications with the TMS320 Family* (literature numbers SPRA012, SPRA016, and SPRA017).

A series of DSP textbooks is published by Prentice-Hall and John Wiley & Sons to support digital signal processing research and education. The TMS320 newsletter, *Details on Signal Processing*, is published quarterly and distributed to update TMS320 customers on product information. The TMS320 DSP bulletin board service (BBS) provides access to information pertaining to the TMS320 family, including documentation, source code and object code for many DSP algorithms and utilities. The BBS can be reached at 281/274-2323.

Information regarding TI DSP products is also available on the Worldwide Web at <http://www.ti.com> uniform resource locator (URL).

electrical characteristics and operating conditions — 'C541, 'C542

absolute maximum ratings over specified temperature range (unless otherwise noted)[†]

| | |
|---|----------------|
| Supply voltage range, V_{DD} [‡] | –0.3 V to 7 V |
| Input voltage range | –0.3 V to 7 V |
| Output voltage range | –0.3 V to 7 V |
| Operating case temperature range, T_C | –40°C to 100°C |
| Storage temperature range, T_{stg} | –55°C to 150°C |

[†] Stresses beyond those listed under “absolute maximum ratings” may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under “recommended operating conditions” is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

[‡] All voltage values are with respect to V_{SS} .

PARAMETER MEASUREMENT INFORMATION

timing parameter symbology

Timing parameter symbols used are created in accordance with JEDEC Standard 100-A. To shorten the symbols, some of the pin names and other related terminology have been abbreviated as follows:

Lowercase subscripts and their meanings:

| | |
|-----|--|
| a | access time |
| c | cycle time (period) |
| d | delay time |
| dis | disable time |
| en | enable time |
| f | fall time |
| h | hold time |
| r | rise time |
| su | setup time |
| t | transition time |
| v | valid time |
| w | pulse duration (width) |
| X | Unknown, changing, or don't care level |

Letters and symbols and their meanings:

| | |
|---|----------------|
| H | High |
| L | Low |
| V | Valid |
| Z | High impedance |

signal transition reference points

All timing references are made at a voltage of 1.5 volts, except rise and fall times which are referenced at the 10% and 90% points of the specified low and high logic levels, respectively.

Where: I_{OL} = 2 mA (all outputs)
 I_{OH} = 300 μ A (all outputs)
 V_{Load} = 1.5 V
 C_T = 40 pF typical load circuit capacitance.

PARAMETER MEASUREMENT INFORMATION

Where: I_{OL} = 1.5 mA (all outputs)
 I_{OH} = 300 μ A (all outputs)
 V_{Load} = 1.5 V
 C_T = 40 pF typical load circuit capacitance.

Figure 12. 3.3-V Test Load Circuit

internal oscillator with external crystal

The internal oscillator is enabled by selecting the appropriate clock mode at reset (this is device dependent – see PLL section) and connecting a crystal or ceramic resonator across X1 and X2/CLKIN. The CPU clock frequency is one-half the crystal's oscillation frequency following reset. After reset, the clock mode of the devices with the software PLL can also be changed to divide-by-four.

The crystal should be in fundamental mode operation and parallel resonant with an effective series resistance of 30ohms and power dissipation of 1 mW. The connection of the required circuit, consisting of the crystal and two load capacitors, is shown in Figure 13. The load capacitors, C_1 and C_2 , should be chosen such that the equation below is satisfied. C_L in the equation is the load specified for the crystal.

$$C_L = \frac{C_1 C_2}{(C_1 + C_2)}$$

[‡] It is recommended that the PLL clocking option be used for maximum frequency operation.

Figure 13. Internal Divide-by-Two Clock Option With External Crystal

TMS320C54x, TMS320LC54x, TMS320VC54x FIXED-POINT DIGITAL SIGNAL PROCESSORS

SPRS039C – FEBRUARY 1996 – REVISED DECEMBER 1999

divide-by-two/divide-by-four clock option – PLL disabled

The frequency of the reference clock provided at the X2/CLKIN pin can be divided by a factor of two or four to generate the internal machine cycle. The selection of the clock mode is described in the clock generator section.

When an external clock source is used, the frequency injected must conform to specifications listed in the timing requirements table.

switching characteristics over recommended operating conditions [$H = 0.5t_{c(CO)}$] (see Figure 13 and Figure 14, and the recommended operating conditions table)

multiply-by-N clock option – PLL enabled

The frequency of the reference clock provided at the X2/CLKIN pin can be multiplied by a factor of N to generate the internal machine cycle. The selection of the clock mode and the value of N is described in the clock generator section.

When an external clock source is used, the frequency injected must conform to specifications listed in the timing requirements table.

switching characteristics over recommended operating conditions for multiply-by-N clock option – PLL enabled [$H = 0.5t_{c(CO)}$] (see Figure 13 and Figure 15, and the recommended operating conditions table)

| PARAMETER | | 'C54x-40 'LC54x-40 | | | 'LC54x-50 | | | '54x-66 | | | UNIT |

reset, $\overline{\text{BIO}}$, interrupt, and $\text{MP}/\overline{\text{MC}}$ timings

timing requirements for reset, interrupt, $\overline{\text{BIO}}$, and $\text{MP}/\overline{\text{MC}}$ [$H = 0.5 t_{\text{c}}(\text{CO})$] (see Figure 26, Figure 27, and Figure 28)

| | | 'C54x-40 'LC54x-40 | | 'LC54x-50 | | '54x-66 | | UNIT |
|---------------------------------------|---|-----------------------|-----|-----------|-----|---------|-----|------|
| | | MIN | MAX | MIN | MAX | MIN | MAX | |
| $t_{\text{h}}(\text{RS})$ | Hold time, $\overline{\text{RS}}$ after CLKOUT low | 0 | | 0 | | 0 | | ns |
| $t_{\text{h}}(\text{BIO})$ | Hold time, $\overline{\text{BIO}}$ after CLKOUT low | 0 | | 0 | | 0 | | ns |
| $t_{\text{h}}(\text{INT})$ | Hold time, $\overline{\text{INTn}}$, $\overline{\text{NMI}}$, after CLKOUT low [†] | 0 | | 0 | | 0 | | ns |
| $t_{\text{h}}(\text{MPMC})$ | Hold time, $\text{MP}/\overline{\text{MC}}$ after CLKOUT low | 0 | | 0 | | 0 | | ns |
| $t_{\text{w}}(\text{RSL})$ | Pulse duration, $\overline{\text{RS}}$ low ^{‡§¶} | 4H+10 | | 4H+10 | | 4H+10 | | ns |
| $t_{\text{w}}(\text{BIO})\text{S}$ | Pulse duration, $\overline{\text{BIO}}$ low, synchronous | 2H+15 | | 2H+12 | | 2H+10 | | ns |
| $t_{\text{w}}(\text{BIO})\text{A}$ | Pulse duration, $\overline{\text{BIO}}$ low, asynchronous | 4H | | 4H | | 4H | | ns |
| $t_{\text{w}}(\text{INTH})\text{S}$ | Pulse duration, $\overline{\text{INTn}}$, $\overline{\text{NMI}}$ high (synchronous) | 2H+15 | | 2H+12 | | 2H+10 | | ns |
| $t_{\text{w}}(\text{INTH})\text{A}$ | Pulse duration, $\overline{\text{INTn}}$, $\overline{\text{NMI}}$ high (asynchronous) | 4H | | 4H | | 4H | | ns |
| $t_{\text{w}}(\text{INTL})\text{S}$ | Pulse duration, $\overline{\text{INTn}}$, $\overline{\text{NMI}}$ low (synchronous) | 2H+15 | | 2H+12 | | 2H+10 | | ns |
| $t_{\text{w}}(\text{INTL})\text{A}$ | Pulse duration, $\overline{\text{INTn}}$, $\overline{\text{NMI}}$ low (asynchronous) | 4H | | 4H | | 4H | | ns |
| $t_{\text{w}}(\text{INTL})\text{WKP}$ | Pulse duration, $\overline{\text{INTn}}$, $\overline{\text{NMI}}$ low for IDLE2/IDLE3 wakeup | 10 | | 10 | | 10 | | ns |
| $t_{\text{su}}(\text{RS})$ | Setup time, $\overline{\text{RS}}$ before X2/CLKIN low [§] | 5 | | 5 | | 5 | | ns |
| $t_{\text{su}}(\text{BIO})$ | Setup time, $\overline{\text{BIO}}$ before CLKOUT low | 15 | | 12 | | 10 | | ns |
| $t_{\text{su}}(\text{INT})$ | Setup time, $\overline{\text{INTn}}$, $\overline{\text{NMI}}$, $\overline{\text{RS}}$ before CLKOUT low | 15 | | 12 | | 10 | | ns |
| $t_{\text{su}}(\text{MPMC})$ | Setup time, $\text{MP}/\overline{\text{MC}}$ before CLKOUT low | 10 | | 10 | | 10 | | ns |

[†] The external interrupts ($\overline{\text{INT0}}-\overline{\text{INT3}}$, $\overline{\text{NMI}}$) are synchronized to the core CPU by way of a two flip-flop synchronizer which samples these inputs with consecutive falling edges of CLKOUT. The input to the interrupt pins is required to represent a 1–0–0 sequence at the timing that is corresponding to three CLKOUTs sampling sequence.

[‡] If the PLL mode is selected, then at power-on sequence, or at wakeup from IDLE3, $\overline{\text{RS}}$ must be held low for at least 50 μs to assure synchronization and lock-in of the PLL.

[§] Divide-by-two mode

[¶] Note that $\overline{\text{RS}}$ may cause a change in clock frequency, therefore changing the value of H (see the PLL section).

| $t_w(SCK)$ Pulse duration, serial port clock low/high | 3H | | 3H | | 3H | | ns |

† The serial port design is fully static and, therefore, can operate with $t_c(SCK)$ approaching ∞ . It is characterized approaching an input frequency of 0 Hz but tested at a much higher frequency to minimize test time.

‡ If the FSX pulse does not meet this specification, the first bit of serial data is driven on DX until the falling edge of FSX. After the falling edge of FSX, data is shifted out on DX pin. The transmit buffer-empty interrupt is generated when the $t_h(FSX)$ and $t_h(FSX)H$ specification is met.

NOTE 1: Internal clock with external FSX and vice versa are also allowable. However, FSX timings to CLKX always are defined depending on the source of FSX, and CLKX timings always are dependent upon the source of CLKX. Specifically, the relationship of FSX to CLKX is independent of the source of CLKX.

† The serial-port design is fully static and, therefore, can operate with $t_{c(SCK)}$ approaching infinity. It is characterized approaching an input frequency of 0 Hz but tested at a much higher frequency to minimize test time.

‡ TFRM timing and waveforms shown in Figure 38 are for external TFRM. TFRM can also be configured as internal. The TFRM internal case is illustrated in the transmit timing diagram in Figure 39.

SPRS039C – FEBRUARY 1996 – REVISED DECEMBER 1999

serial-port receive timing in TDM mode (continued)

[†] All devices except '542/'543

[‡] '542/'543 only

Figure 38. Serial-Port Receive Timing in TDM Mode

serial-port transmit timing in TDM mode

switching characteristics over recommended operating conditions for serial-port transmit in TDM mode [$H = 0.5t_{c(CO)}$] (see Figure 39)

| PARAMETER | | '542 '543 | 'C54x-40 'LC54x-40 'LC54x-50 | UNIT |
|-----------------------|--|--------------|------------------------------------|------|
| | | MIN | MAX | |
| $t_h(\text{TCH-TDV})$ | Hold time, TDAT/TADD valid after TCLK rising edge, TCLK external | 3 | 0 | ns |
| $t_h(\text{TCH-TDV})$ | Hold time, TDAT/TADD valid after TCLK rising edge, TCLK internal | 1 | -5 | ns |
| $t_d(\text{TCH-TFV})$ | Delay time, TFRM valid after TCLK rising edge, TCLK ext [†] | $H - 3$ | $3H + 22$ | ns |
| | Delay time, TFRM valid after TCLK rising edge, TCLK int [†] | $H - 3$ | $3H + 12$ | |
| $t_d(\text{TC-TDV})$ | Delay time, TCLK to valid TDAT/TADD, TCLK ext | | 18 | ns |
| | Delay time, TCLK to valid TDAT/TADD, TCLK int | | 18 | |

[†] TFRM timing and waveforms shown in Figure 39 are for internal TFRM. TFRM can also be configured as external. The TFRM external case is illustrated in the receive timing diagram in Figure 38.

switching characteristics over recommended operating conditions for serial-port transmit in TDM mode [$H = 0.5t_{c(CO)}$] (see Figure 39)

| PARAMETER | | '54x-66 | | UNIT |
|-----------------------|--|---------|-----------|------|
| | | MIN | MAX | |
| $t_h(\text{TCH-TDV})$ | Hold time, TDAT/TADD valid after TCLK rising edge, TCLK external | 1 | | ns |
| $t_h(\text{TCH-TDV})$ | Hold time, TDAT/TADD valid after TCLK rising edge, TCLK internal | 1 | | ns |
| $t_d(\text{TCH-TFV})$ | Delay time, TFRM valid after TCLK rising edge, TCLK ext [†] | $H - 3$ | $3H + 22$ | ns |
| | Delay time, TFRM valid after TCLK rising edge, TCLK int [†] | $H - 3$ | $3H + 12$ | |
| $t_d(\text{TC-TDV})$ | Delay time, TCLK to valid TDAT/TADD, TCLK ext | | 25 | ns |
| | Delay time, TCLK to valid TDAT/TADD, TCLK int | | 18 | |

[†] TFRM timing and waveforms shown in Figure 39 are for internal TFRM. TFRM can also be configured as external. The TFRM external case is illustrated in the receive timing diagram in Figure 38.

TMS320C54x, TMS320LC54x, TMS320VC54x FIXED-POINT DIGITAL SIGNAL PROCESSORS

SPRS039C – FEBRUARY 1996 – REVISED DECEMBER 1999

serial-port transmit timing in TDM mode (continued)

timing requirements for serial-port transmit in TDM mode [$H = 0.5t_{c(CO)}$] (see Figure 39)

| | | 'C54x-40 'LC54x-40 'LC54x-50 | | '54X-66 | | UNIT |
|------------|--|------------------------------------|-----|------------------|-----|------|
| | | MIN | MAX | MIN | MAX | |
| $t_c(SCK)$ | Cycle time, serial-port clock | 8H [†] | ‡ | 16H [†] | ‡ | ns |
| $t_f(SCK)$ | Fall time, serial-port clock | | 6 | | 6 | ns |
| $t_r(SCK)$ | Rise time, serial-port clock | | 6 | | 6 | ns |
| $t_w(SCK)$ | Pulse duration, serial-port clock low/high | 4H [†] | | 8H [†] | | ns |

[†] When SCK is generated internally, this value is typical.

[‡] The serial-port design is fully static and, therefore, can operate with $t_c(SCK)$ approaching ∞ . It is characterized approaching an input frequency of 0 Hz but tested as a much higher frequency to minimize test time.

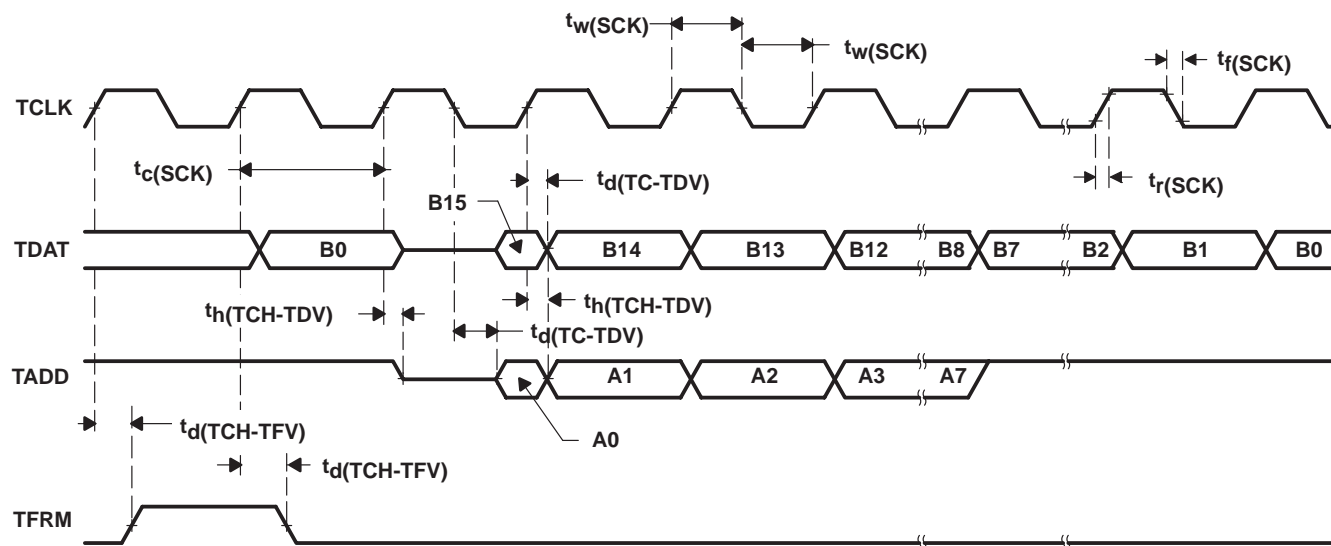

Figure 39. Serial-Port Transmit Timing in TDM Mode

host-port interface timing

switching characteristics over recommended operating conditions for host-port interface
[H = 0.5t_{c(CO)}] (see Note 5, Note 6, and Figure 40 through Figure 43)

| PARAMETER | | 'C54x-40 'C54x-50 'C54x-66 | UNIT |
|---------------------------|--|---|------|
| | | MIN MAX | |
| t _d (DSL-HDV) | Delay time, \overline{DS} low to HD driven | 5 12 | ns |
| t _d (HEL-HDV1) | Delay time, HDS falling to HD valid for first byte of a non-subsequent read: → max 20 ns ^{†‡} | Case 1: Shared-access mode if t _w (DSH) < 7H | ns |
| | | Case 2: Shared-access mode if t _w (DSH) > 7H | |
| | | Case 3: Host-only mode if t _w (DSH) < 20 ns | |
| | | Case 4: Host-only mode if t _w (DSH) > 20 ns | |
| t _d (DSL-HDV2) | Delay time, \overline{DS} low to HD valid, second byte | 5 [‡] 20 | ns |
| t _d (DSH-HYH) | Delay time, \overline{DS} high to HRDY high | 10H+10 | ns |
| t _{su} (HDV-HYH) | Setup time, HD valid before HRDY rising edge | 3H–10 | ns |
| t _h (DSH-HDV)R | Hold time, HD valid after \overline{DS} rising edge, read | 0 12 | ns |
| t _d (COH-HYH) | Delay time, CLKOUT rising edge to HRDY high | 10 | ns |
| t _d (DSH-HYL) | Delay time, \overline{HDS} or \overline{HCS} high to HRDY low | 12 | ns |
| t _d (COH-HTX) | Delay time, CLKOUT rising edge to \overline{HINT} change | 15 | ns |

[†] Host-only mode timings apply for read accesses to HPIC or HPIA, write accesses to BOB, and resetting DSPINT or HINT to 0 in shared-access mode. HRDY does not go low for these accesses.

[‡] Shared-access mode timings will be met automatically if HRDY is used.

NOTES: 5. SAM = shared-access mode, HOM = host-only mode
HAD stands for HCNTRL0, HCNTRL1, and HR/ \overline{W} .
 \overline{HDS} refers to either $\overline{HDS1}$ or $\overline{HDS2}$.
 \overline{DS} refers to the logical OR of \overline{HCS} and \overline{HDS} .

6. On host read accesses to the HPI, the setup time of HD before \overline{DS} rising edge depends on the host waveforms and cannot be specified here.

TMS320C54x, TMS320LC54x, TMS320VC54x FIXED-POINT DIGITAL SIGNAL PROCESSORS

SPRS039C – FEBRUARY 1996 – REVISED DECEMBER 1999

host-port interface timing (continued)

timing requirements for host-port interface [$H = 0.5t_{c(CO)}$] (see Note 5 and Figure 40 through Figure 43)

| | | 'C54x-40 'C54x-50 'C54x-66 | UNIT |
|---------------------------|--|---|------|
| | | MIN MAX | |
| $t_{su}(HBV-DSL)$ | Setup time, HAD/HBIL valid before \overline{DS} or \overline{HAS} falling edge | 10 | ns |
| $t_h(DSL-HBV)$ | Hold time, HAD/HBIL valid after \overline{DS} or \overline{HAS} falling edge | 5 | ns |
| $t_{su}(HSL-DSL)$ | Setup time, \overline{HAS} low before \overline{DS} falling edge | 12 | ns |
| $t_w(DSL)$ | Pulse duration, \overline{DS} low | 30 [†] | ns |
| $t_w(DSH)$ | Pulse duration, \overline{DS} high | 10 | ns |
| $t_c(DSH-DSH)^{\dagger}$ | Cycle time, \overline{DS} rising edge to next \overline{DS} rising edge | Case 1: HOM access timings (see Access Timing Without HRDY) | ns |
| | | Case 2a: SAM accesses and HOM active writes to DSPINT or HINT. (see Access Timings With HRDY) | |
| $t_{su}(HDV-DSH)$ | Setup time, HD valid before \overline{DS} rising edge | 12 | ns |
| $t_d(DSH-HSL)^{\ddagger}$ | Delay time, \overline{DS} high to next \overline{HAS} low | 10H | ns |
| $t_h(DSH - HDV)W$ | Hold time, HD valid after \overline{DS} rising edge, write | 3 | ns |

[†] A host not using HRDY should meet the 10H requirement all the time unless a software handshake is used to change the access rate according to the HPI mode.

[‡] Must only be met if \overline{HAS} is going low when not accessing the HPI (as would be the case where multiple devices are being driven by one host).

NOTE 5: SAM = shared-access mode, HOM = host-only mode

HAD stands for HCNTRL0, HCNTRL1, and HR/W.

HDS refers to either HDS1 or HDS2.

\overline{DS} refers to the logical OR of HCS and HDS.

IMPORTANT NOTICE

Texas Instruments and its subsidiaries (TI) reserve the right to make changes to their products or to discontinue any product or service without notice, and advise customers to obtain the latest version of relevant information to verify, before placing orders, that information being relied on is current and complete. All products are sold subject to the terms and conditions of sale supplied at the time of order acknowledgement, including those pertaining to warranty, patent infringement, and limitation of liability.

TI warrants performance of its semiconductor products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are utilized to the extent TI deems necessary to support this warranty. Specific testing of all parameters of each device is not necessarily performed, except those mandated by government requirements.

CERTAIN APPLICATIONS USING SEMICONDUCTOR PRODUCTS MAY INVOLVE POTENTIAL RISKS OF DEATH, PERSONAL INJURY, OR SEVERE PROPERTY OR ENVIRONMENTAL DAMAGE ("CRITICAL APPLICATIONS"). TI SEMICONDUCTOR PRODUCTS ARE NOT DESIGNED, AUTHORIZED, OR WARRANTED TO BE SUITABLE FOR USE IN LIFE-SUPPORT DEVICES OR SYSTEMS OR OTHER CRITICAL APPLICATIONS. INCLUSION OF TI PRODUCTS IN SUCH APPLICATIONS IS UNDERSTOOD TO BE FULLY AT THE CUSTOMER'S RISK.

In order to minimize risks associated with the customer's applications, adequate design and operating safeguards must be provided by the customer to minimize inherent or procedural hazards.

TI assumes no liability for applications assistance or customer product design. TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right of TI covering or relating to any combination, machine, or process in which such semiconductor products or services might be or are used. TI's publication of information regarding any third party's products or services does not constitute TI's approval, warranty or endorsement thereof.

Компания «Океан Электроники» предлагает заключение долгосрочных отношений при поставках импортных электронных компонентов на взаимовыгодных условиях!

Наши преимущества:

- Поставка оригинальных импортных электронных компонентов напрямую с производств Америки, Европы и Азии, а так же с крупнейших складов мира;
- Широкая линейка поставок активных и пассивных импортных электронных компонентов (более 30 млн. наименований);
- Поставка сложных, дефицитных, либо снятых с производства позиций;
- Оперативные сроки поставки под заказ (от 5 рабочих дней);
- Экспресс доставка в любую точку России;
- Помощь Конструкторского Отдела и консультации квалифицированных инженеров;
- Техническая поддержка проекта, помощь в подборе аналогов, поставка прототипов;
- Поставка электронных компонентов под контролем ВП;
- Система менеджмента качества сертифицирована по Международному стандарту ISO 9001;
- При необходимости вся продукция военного и аэрокосмического назначения проходит испытания и сертификацию в лаборатории (по согласованию с заказчиком);
- Поставка специализированных компонентов военного и аэрокосмического уровня качества (Xilinx, Altera, Analog Devices, Intersil, Interpoint, Microsemi, Actel, Aeroflex, Peregrine, VPT, Syfer, Eurofarad, Texas Instruments, MS Kennedy, Miteq, Cobham, E2V, MA-COM, Hittite, Mini-Circuits, General Dynamics и др.);

Компания «Океан Электроники» является официальным дистрибьютором и эксклюзивным представителем в России одного из крупнейших производителей разъемов военного и аэрокосмического назначения «JONHON», а так же официальным дистрибьютором и эксклюзивным представителем в России производителя высокотехнологичных и надежных решений для передачи СВЧ сигналов «FORSTAR».

JONHON

«JONHON» (основан в 1970 г.)

Разъемы специального, военного и аэрокосмического назначения:

(Применяются в военной, авиационной, аэрокосмической, морской, железнодорожной, горно- и нефтедобывающей отраслях промышленности)

«FORSTAR» (основан в 1998 г.)

ВЧ соединители, коаксиальные кабели,
кабельные сборки и микроволновые компоненты:

(Применяются в телекоммуникациях гражданского и специального назначения, в средствах связи, РЛС, а так же военной, авиационной и аэрокосмической отраслях промышленности).
