## Low-Jitter LVDS Fanout Clock Buffers with up to 10 LVDS Outputs from Any-Format Input and Wide Frequency Range from dc up to 1250 MHz

The Si53340-45 family of LVDS fanout buffers is ideal for clock/data distribution and redundant clocking applications. These devices feature typical ultra-low jitter of 50 fs and operate over a wide frequency range from dc to 1250 MHz. Built-in LDOs deliver high PSRR performance and reduces the need for external components simplifying low jitter clock distribution in noisy environments.

They are available in multiple configurations and offer a selectable input clock using a 2:1 input mux. Other features include independent output enable and built-in format translation. These buffers can be paired with the Si534x clocks and Si5xx oscillators to deliver end-to-end clock tree performance.

## 2. Functional Description

The Si53340-45 are a family of low-jitter, low skew, fixed format (LVDS) buffers. The Si53340/42/44 have a universal input that accepts most common differential or LVCMOS input signals, while the Si53341/43/45 accept only LVCMOS inputs. These devices are available in multiple configurations customized for the end application (refer to [1. Ordering Guide](#) for more details on configurations).

### 2.1 Universal, Any-Format Input Termination (Si53340/42/44)

The universal input stage enables simple interfacing to a wide variety of clock formats, including LVPECL, Low-power LVPECL, LVDS, CML, HCSL, and LVCMOS. The tables below summarize the various ac- and dc-coupling options supported by the device. For the best high-speed performance, the use of differential formats is recommended. For both single-ended and differential input clocks, the fastest possible slew rate is recommended since low slew rates can increase the noise floor and degrade jitter performance. Though not required, a minimum slew rate of 0.75 V/ns is recommended for differential formats and 1.0 V/ns for single-ended formats. See [“AN766: Understanding and Optimizing Clock Buffer’s Additive Jitter Performance”](#) for more information.

The table below summarizes the various ac- and dc-coupling options supported by the LVCMOS device, and the figure shows the recommended input clock termination.

## 2.3 Input Bias Resistors

Internal bias resistors ensure a differential output low condition in the event that the clock inputs are not connected. The non-inverting input is biased with a 18.75 k $\Omega$  pull-down to GND and a 75 k $\Omega$  pull-up to V<sub>DD</sub>. The inverting input is biased with a 75 k $\Omega$  pull-up to V<sub>DD</sub>.

**Figure 2.5. Input Bias Resistors**

**Note:** To minimize the possibility of system noise coupling into the Si5334x differential inputs and adversely affecting the buffered output, Silicon Labs recommends 1 PPS clocks and disabled/gapped clocks be DC-coupled and driven “stop-low”.

## 2.4 Input Mux

The Si5334x provide two clock inputs for applications that need to select between one of two clock sources. The CLK\_SEL pin selects the active clock input. The following table summarizes the input and output clock based on the input mux and output enable pin settings.

**Table 2.3. Input Mux Logic**

CLK_SEL	CLK0	CLK1	Q <sup>1</sup>	Qb

## 2.7 Typical Phase Noise Performance: Differential Input Clock

Each of the three phase noise plots superimposes Source Jitter, Total SE Jitter and Total Diff Jitter on the same diagram.

- **Source Jitter**—Reference clock phase noise (measured Single-ended to PNA).
- **Total Jitter (SE)**—Combined source and clock buffer phase noise measured as a single-ended output to the phase noise analyzer and integrated from 12 kHz to 20 MHz.
- **Total Jitter (Diff)**—Combined source and clock buffer phase noise measured as a differential output to the phase noise analyzer and integrated from 12 kHz to 20 MHz. The differential measurement as shown in each figure is made using a balun. For more information, see 3. [Electrical Specifications](#).

**Note:** To calculate the total RMS phase jitter when adding a buffer to your clock tree, use the root-sum-square (RSS).

Figure 2.8. Differential Measurement Method Using a Balun

The total jitter is a measure of the source plus the buffer's additive phase jitter. The additive jitter (rms) of the buffer can then be calculated (via root-sum-square addition).

## 2.8 Typical Phase Noise Performance: Single-Ended Input Clock

For single-ended input phase noise measurements, the input was connected directly without the use of a balun.

The following figure shows three phase noise plots superimposed on the same diagram.

Frequency (MHz)	Single-Ended Input Slew Rate (V/ns)	Source Jitter (fs)	Total Jitter (SE) (fs)	Additive Jitter (SE) (fs)	Total Jitter (Differential) (fs)	Additive Jitter (Differential) (fs)

Figure 2.12. Total Jitter Single-Ended Input (156.25 MHz)

## 2.9 Input Mux Noise Isolation

The input clock mux is designed to minimize crosstalk between the CLK0 and CLK1. This improves phase jitter performance when clocks are present at both the CLK0 and CLK1 inputs. The following figure shows a measurement of the input mux's noise isolation.

Figure 2.13. Input Mux Noise Isolation (Differential Input Clock, 44-QFN Package)

Figure 2.14. Input Mux Noise Isolation (Single-Ended Input Clock, 24-QFN Package)

## 2.10 Power Supply Noise Rejection

The device supports on-chip supply voltage regulation to reject power supply noise and simplify low-jitter operation in real-world environments. This feature enables robust operation alongside FPGAs, ASICs and SoCs and may reduce board-level filtering requirements. See [“AN491: Power Supply Rejection for Low-Jitter Clocks”](#) for more information.
