The SoC has three MIPI clock lanes and five MIPI data lanes. The Analog Front End (AFE) and Digital Physical Layer (DPHY) take these lanes and connects them to three virtual ports. Two data lanes are dedicated to each of the rear facing cameras and the remaining one data lane is connected to the front facing camera. The MIPI interfaces follow the MIPI-CSI-2 specifications as defined by the MIPI Alliance. They support YUV420, YUV422, RGB444, RGB555, RGB565, RGB 888 and RAW 8b/10b/12b. Both MIPI ports support compression settings specified in MIPI-CSI-2 draft specification 1.01.00 Annex E. The compression is implemented in Hardware with support for Predictor 1 and Predictor 2. Supported compression schemes:

- 12-8-12
- 12-7-12
- 12-6-12
- 10-8-10
- 10-7-10
- 10-6-10

The data compression schemes above use an X-Y-Z naming convention where X is the number of bits per pixel in the original image, Y is the encoded (compressed) bits per pixel and Z is the decoded (uncompressed) bits per pixel.

#### 15.3.2.2 Camera Sideband for Camera Interface

Twelve (12) GPIO signals are allocated for camera functions, refer to Table 177 for signal names. These GPIOs are multiplexed and are available for other usages without powering on the ISP. The ISP provides a timing control block through which the GPIOs can be controlled to support assertion, de-assertion, pulse widths and delay. The configuration below of camera GPIOs is just an example of how the GPIOs can be used. Several of these functions could be implemented using $I^2C$, depending on the sensor implementation for the platform.

- Sensor Reset signals

  —Force hardware reset on one or more of the sensors.

- Sensor Single Shot Trigger signal

  —Indicate that the target sensor needs to send a full frame in a single shot mode, or to capture the full frame for flash synchronization.

- PreLight Trigger signal

  —Light up a pilot lamp prior to firing the flash for preventing red-eye.

- Flash Trigger signal

  —Indicate that a full frame is about to be captured. The Flash fires when it detects an assertion of the signal.

- Sensor Strobe Trigger signal

  —Asserted by the target sensor to indicate the start of a full frame, when it is configured in the single shot mode, or to indicate a flash exposed frame for flash synchronization.

## 15.4 Functional Description

At a high level, the Camera Subsystem supports the following modes:

- Preview
- Image capture
- Video capture

### 15.4.1 Preview Mode

Once the ISP and the camera subsystem is enabled, the ISP goes into the preview mode where very low resolution frames, such as VGA/480p (programmable), are being processed.

### 15.4.2 Image Capture

During the image capture mode, the camera subsystem can acquire at a peak throughput of 24 Mpixels @ 15fps. While doing this, it continues to output preview frames simultaneously.

- The ISP can output RAW, RGB or YUV formats. The ISP can capture one full frame at a time or perform burst mode capture, where up to five full back-to-back frames are recorded.
- The ISP will not limit the number of back-to-back full frames captured, but the number is programmable and determined on how much memory can be allocated dynamically.
- The ISP can process all the frames on the fly and writes to memory only after fully processing the frames, without requiring download of any part of the frame for further processing.
  - —The exceptions to this approach are image stabilization and some other advanced functions requiring temporal information over multiple frames.

The ISP can support image stabilization in image capture model.

- The ISP initially outputs preview frames.
- When the user decides to capture the picture, image stabilization is enabled. The ISP checks the previous frame for motion and compensates for it appropriately.

Auto Exposure (AE), Auto Focus (AF), and Auto White Balance (AWB), together known as 3A, are implemented in the CPU to provide flexibility.

### 15.4.3 Video Capture

During video recording, the ISP can capture video up to 1080p @ 60 fps and output preview frames concurrently. The ISP output video frames to memory in YUV420 or YUV422 format.

### 15.4.4 ISP Overview

The Camera Subsystem consists of 2 parts, the hardware subsystem and a software stack that implements the ISP functionality on top of this hardware.

The core of the ISP is a vector processor. The vector processor is supported by the following components:

- Interfaces for data and control
- A small input formatter that parallelizes the data
- A scalar (RISC) processor, for system control and low-rate processing
- An accelerator for scaling, digital zoom, and lens distortion correction
- A DMA engine transfers large amounts of data such as input and output image data or large parameter sets between LPDDR2 and the ISP block.

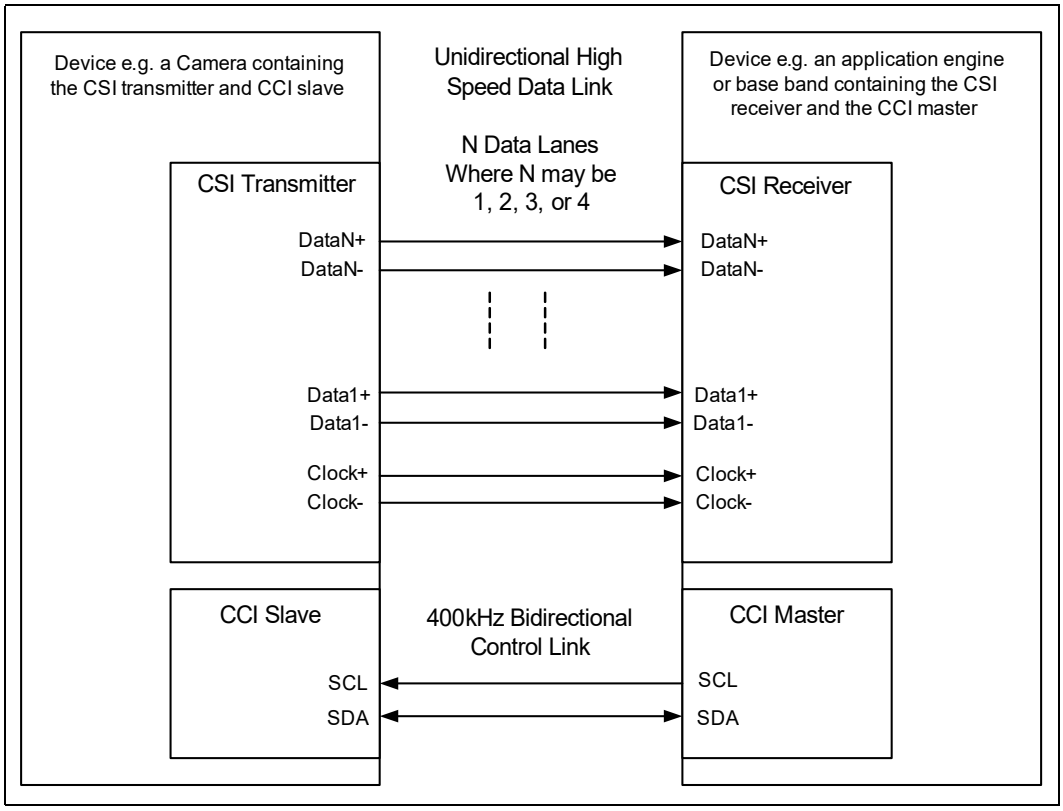
## 15.4.5 Memory Management Unit (MMU)

The camera subsystem has capabilities to deal with a virtual address space, since a contiguous memory range in the order 16–32MB cannot be guaranteed by the OS.

### 15.4.5.1 Interface

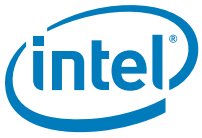
The MMU performs the lookup required for address translation from a virtual to physical 32-bit address. The lookup tables are stored external to the system. The MMU performs the lookup through a master interface without burst support that is connected to the Open Core Protocol (OCP) master of the subsystem. The MMU configuration registers can be accessed through a 32-bit Core I/O (CIO) slave interface. Additionally there is a 32-bit CIO slave interface connected to the address translator.

## 15.5 MIPI-CSI-2 Receiver



MIPI-CSI-2 devices are camera serial interface devices. They are categorized into two types, a CSI transmitter device with Camera Control Interface (CCI) slave and CSI receiver device with CCI master.

Data transfer by means of MIPI-CSI is unidirectional that is, from transmitter to receiver. CCI data transfer is bidirectional between the CCI slave and master.



Camera Serial Interface Bus (CSI) is a type of serial bus that enables transfer of data between a Transmitter device and a receiver device. The CSI device has a point-to-point connections with another CSI device by means of D-PHYs and as shown in Figure 96.

Similarly, CCI (Camera Control Interface bus) is a type of serial bus that enables transfer back and forth between the master CCI and a Slave CCI Unit.

**Figure 96. MIPI-CSI Bus Block Diagram**

D-PHY data lane signals are transferred point-to-point differentially using two signal lines and a clock lane. There are two signaling modes, a high speed mode that operates at 1000Mbs and a low power mode that works at 10Mbs. The mode is set to low power mode and a stop state at start up/power up. Depending on the desired data transfer type, the lanes switch between high and low power modes.

The CCI interface consists of an $I^2C$ bus which has a clock line and a bidirectional data line.

The MIPI-CSI-2 devices operate in a layered fashion. There are 5 layers identified at the receiver and transmitter ends.

MIPI-CSI-2 Functional Layers:

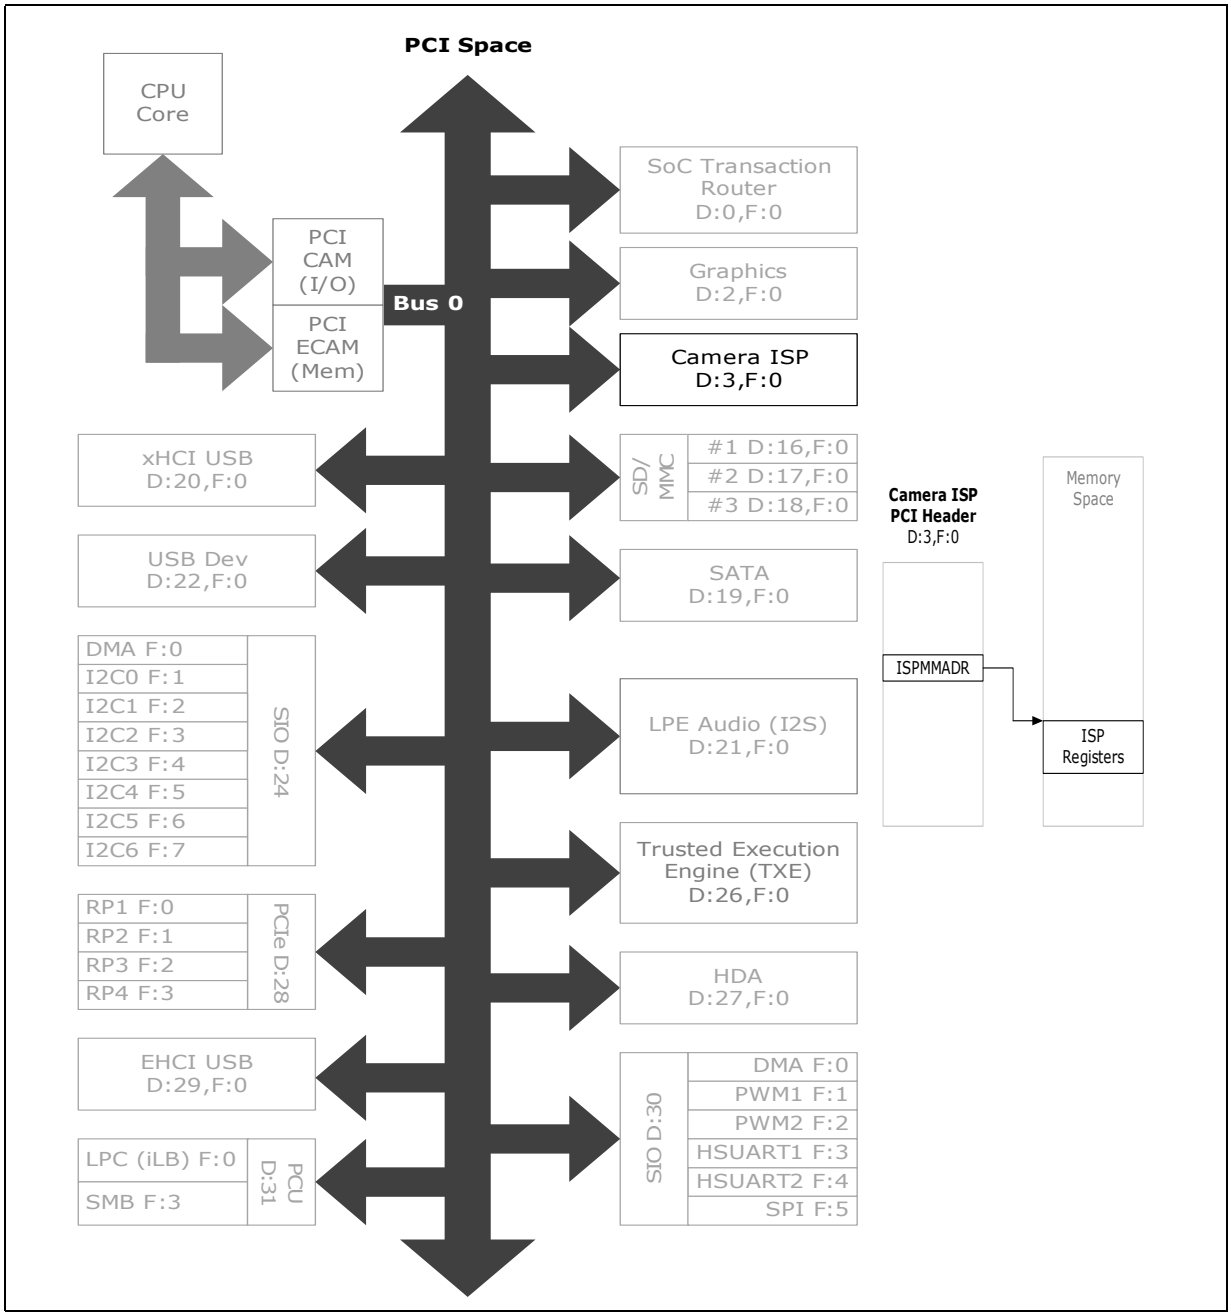
- **PHY Layer**:
  - An embedded electrical layer sends and detects start of packet signalling and end of packet signalling on the data lanes. It contains a serializer and deserializer unit to interface with the PPI / lane management unit. There is also a clock divider unit to source and receive the clock during different modes of operation.
- **PPI/Lane Management Unit**:
  - This layer does the lane buffering and distributes the data in the lanes as programmed in a round robin manner and also merges them for the PLI/Low Level Protocol unit.
- **PLI/Low Level Protocol Unit**:
  - This layer packetizes as well as de-packetizes the data with respect to channels, frames, colors and line formats. There are ECC generator and corrector units to recover the data free from errors in the packet headers. There is also a CRC checker or CRC generator unit to pack the payload data with CRC checksum bits for payload data protection.
- **Pixel/Byte to Byte/Pixel Packing Formats**:
  - Conversion of pixel formats to data bytes in the payload data is done depending on the type of image data supported by the application. It also re-converts the raw data bytes to pixel format understandable to the application layer.
- **Application**:
  - Depending on the type of formats, camera types, capability of the camera used by the transmitter, the application layer recovers the image formats and reproduces the image in the display unit. It also works on de-framing the data into pixel-to-packing formats. High level encoding and decoding of image data is handled in the application unit.

### 15.5.1 MIPI-CSI-2 Receiver Features

CSI Features:

- Compliant to CSI-2 MIPI specification for Camera Serial Interface (Version 1.00)
- Supports standard D-PHY transceiver compliant to the MIPI Specification
- Supports PHY data programmability up to four lanes.
- Supports PHY data time-out programming.
- Has controls to start and re-start the CSI-2 data transmission for synchronization failures and to support recovery.

- The ISP may not support all the data formats that the CSI-2 receiver can handle.
  —Refer to Table 178 for formats supported by the ISP
- Supports all generic short packet data types.
- Single Image Signal Processor interface for pixel transfers to support multiple image streams for all virtual channel numbers.



D-PHY Features:

- Supports synchronous transfer in high speed mode with a bit rate of 80-1000Mb/s
- Supports asynchronous transfer in low power mode with a bit rate of 10Mb/s.
- Differential signalling for HS data
- Spaced one-hot encoding for Low Power [LP] data
- Data lanes support transfer of data in high speed as well as low power modes.
- Supports ultra low power mode, escape mode, and high speed mode
- Has a clock divider unit to generate clock for parallel data reception and transmission from and to the PPI unit.
- Activates and disconnects high speed terminators for reception and control mode.
- Activates and disconnects low power terminators for reception and transmission.

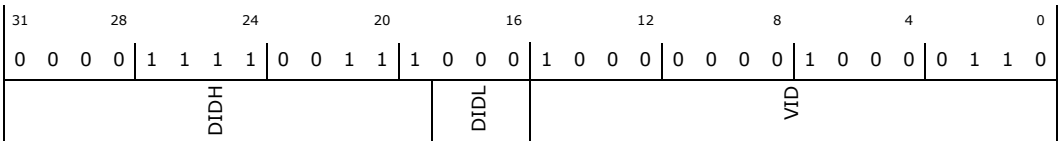
## 15.7.1 iunit_ID_type (ID)—Offset 0h



PCI Device and Vendor ID Register

### Access Method

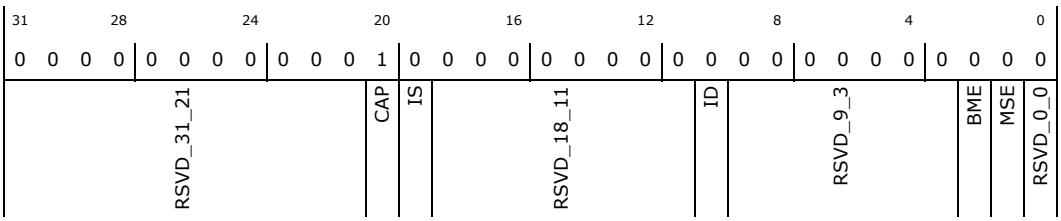
**Type:** PCI Configuration Register (Size: 32 bits)

**ID:** [B:0, D:3, F:0] + 0h

**Default:** 0F388086h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31:19 | 01E7h RO | **DIDH:** DEVICE_IDENTIFICATION_NUMBER_HIGH: Upper bits of ISP Device ID. Connected to straps at IUNIT top level. (Tangier IUNIT Device IDs range from 16'h1178 through 16'h117F. Valleyview IUNIT Device IDs range from 16'h0F38 through 16'h0F3F.) |
| 18:16 | 000b RO | **DIDL:** DEVICE_IDENTIFICATION_NUMBER_LOW: Lower bits of ISP Device ID. Connected to fuse FB_isp_device_id. (Tangier IUNIT Device IDs range from 16'h1178 through 16'h117F. Valleyview IUNIT Device IDs range from 16'h0F38 through 16'h0F3F.) |
| 15:0 | 8086h RO | **VID:** VENDOR_IDENTIFICATION_NUMBER: PCI standard identification for Intel. |

## 15.7.2 iunit_PCICMDSTS_type (PCICMDSTS)—Offset 4h



PCI Command and Status Register

### Access Method

**Type:** PCI Configuration Register (Size: 32 bits)

**PCICMDSTS:** [B:0, D:3, F:0] + 4h

**Default:** 00100000h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31:21 | 0h<br>RO | **RSVD_31_21:** Reserved |
| 20 | 1b<br>RO | **CAP:** CAPABILITY_LIST: Indicates that the CAPPOINT register at 34h provides an offset into PCI Configuration Space containing a pointer to the location of the first item in the list. |
| 19 | 0b<br>RO | **IS:** INTERRUPT_STATUS: Reflects the state of the interrupt in the camera device. Is set to 1 if IER and IIR are both set. Otherwise is set to 0. |
| 18:11 | 0h<br>RO | **RSVD_18_11:** Reserved |
| 10 | 0b<br>RW | **ID:** INTERRUPT_DISABLE: When 1, blocks the sending of ASSERT_INTA and DEASSERT_INTA messages to the Intel Legacy Block (ILB). The interrupt status is not blocked from being reflected in PCICMDSTS.IS. When 0, permits the sending of ASSERT_INTA and DEASSERT_INTA messages to the ILB. |
| 9:3 | 0h<br>RO | **RSVD_9_3:** Reserved |
| 2 | 0h<br>RW | **BME:** BUS_MASTER_ENABLE: Enables ISP to function as a PCI compliant master. When 0, blocks the sending of MSI interrupts. When 1, permits the sending of MSI interrupts. |
| 1 | 0h<br>RW | **MSE:** MEMORY_SPACE_ENABLE: When set, accesses to this device's memory space is enabled. When 1, the ISP will compare the incoming address on the IOSF bus with ISPMMADR(31:22). If there is a match and if the IOSF command is either a MEMRD or MEMWR, the ISP will select the command and present it on the AHB bus. When 0, the ISP will not claim MEMRD or MEMWR IOSF commands. |

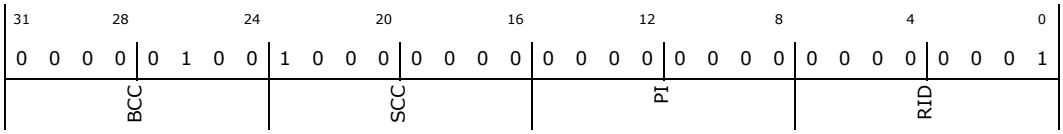
## 15.7.3 iunit_RIDCC_type (RIDCC)—Offset 8h



Revision Identification and Class Codes

### Access Method

**Type:** PCI Configuration Register (Size: 32 bits)

**RIDCC:** [B:0, D:3, F:0] + 8h

**Default:** 04800001h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31:24 | 04h<br>RO | **BCC:** BASE_CLASS_CODE: Indicates a multimedia device. |

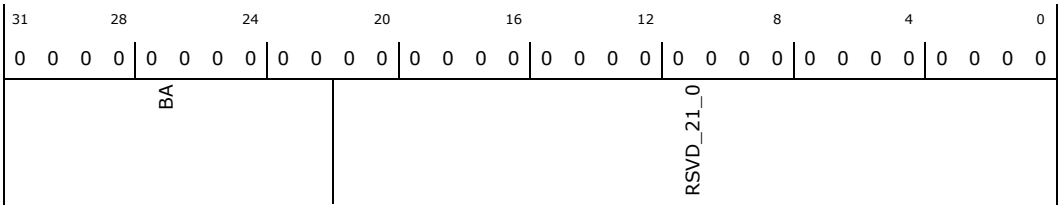
## 15.7.5 iunit_ISPMMADR_type (ISPMMADR)—Offset 10h



Memory Mapped Address Range. This is the base address for all memory mapped registers.

### Access Method

**Type:** PCI Configuration Register (Size: 32 bits)

**ISPMMADR:** [B:0, D:3, F:0] + 10h

**Default:** 00000000h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31:22 | 0h<br>RW | **BA:** BASE_ADDRESS: Set by the OS, these bits correspond to address signals (31:22). The ISP will compare the IOSF address (31:22) with ISPMMADR(31:22). If there is a match, and PCICMDSTS(1) = MSE = 1 and the IOSF command is either a MEMRD or MEMWR, the ISP will select the command and present it on the AHB bus to the vendor IP. |

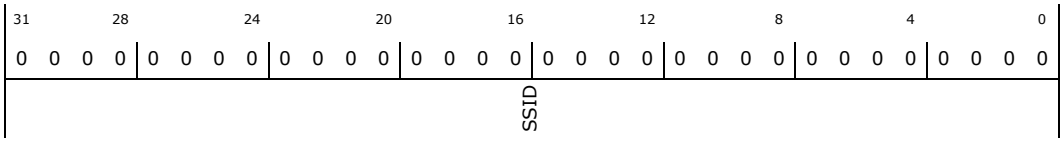
## 15.7.6 iunit_SSID_type (SSID)—Offset 2Ch



Subsystem Identifiers

### Access Method

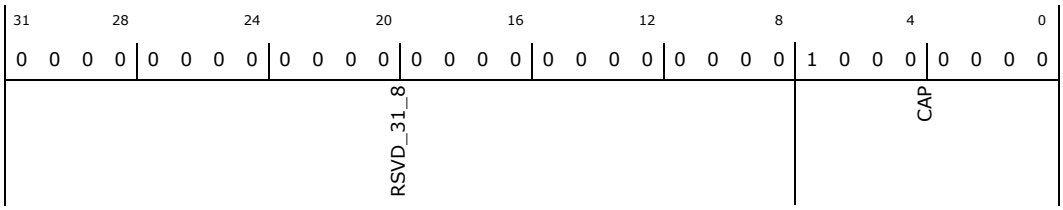
**Type:** PCI Configuration Register (Size: 32 bits)

**SSID:** [B:0, D:3, F:0] + 2Ch

**Default:** 00000000h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31:0 | 0h<br>RO | **SSID:** SUBSYSTEM_IDENTIFIERS: The value in this field is a copy of the SSID register programmed by the graphics device driver or BIOS in the Device 0/2/0 PCI header. To change the subsystem ID, write to Device 0/2/0 SSID instead of to this SSID. |

## 15.7.7 iunit_CAPPOINT_type (CAPPOINT)—Offset 34h



Capabilities Pointer

### Access Method

**Type:** PCI Configuration Register (Size: 32 bits)

**CAPPOINT:** [B:0, D:3, F:0] + 34h

**Default:** 00000080h

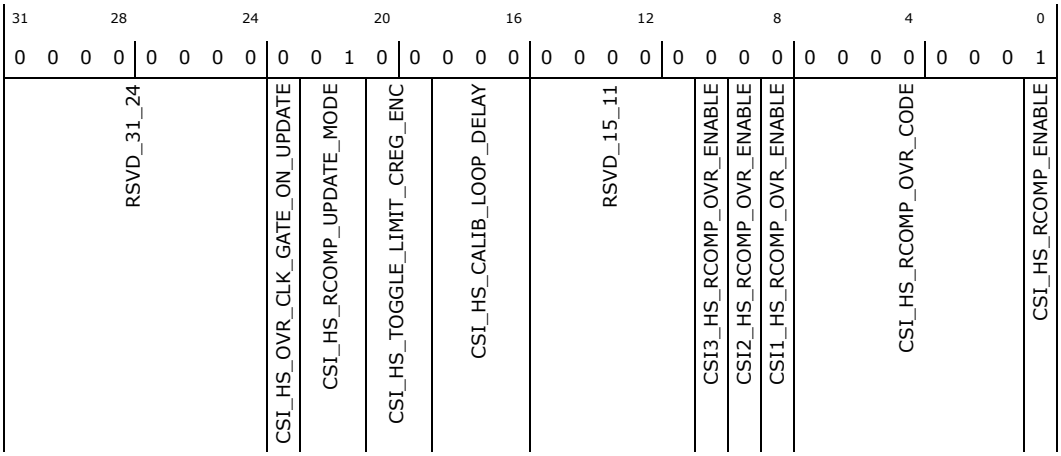
The firmware running on the ISP guarantees ordering by reading the last data write from memory before raising the interrupt. 1 = If MSI_ENABLE is set, then an MSI is sent to the CPU when the IIR bit is set, or if the IIR bit remains set after software writes to this register. If INTERRUPT_DISABLE is not set, then an ASSERT_INTA message is sent to the Intel Legacy Block (ILB) when the IIR bit is set by hardware, or if the IIR bit remains set after software writes to this register. If software clears the IIR bit, and INTERRUPT_DISABLE is not set then a DEASSERT_INTA message is sent to the ILB. 0 = Do not generate an MSI even if the MSI_ENABLE bit is set. ## 15.7.32 iunit_IUNIT_RCOMP_CONTROL_type (IUNIT_RCOMP_CONTROL)—Offset F4h



MIPI CSI RCOMP control register

### Access Method

**Type:** PCI Configuration Register (Size: 32 bits)

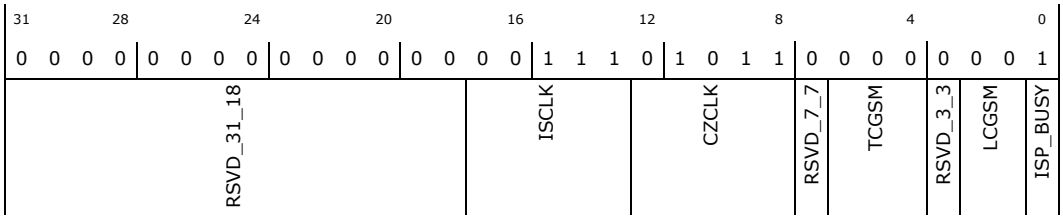
**IUNIT_RCOMP_CONTROL:** [B:0, D:3, F:0] + F4h

**Default:** 00200001h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31:24 | 0h<br>RW | **RSVD_31_24:** Reserved |
| 23 | 0b<br>RW | **CSI_HS_OVR_CLK_GATE_ON_UPDATE:** CSI_HS_OVR_CLK_GATE_ON_UPDATE: If cleared, the high speed clock going to the digital logic is gated when RCOMP update is happening. The clock is gated for a minimum of 100 nsec. If this bit is set, then the high speed clock is not gated during the update cycle. |
| 22:21 | 01b<br>RW | **CSI_HS_RCOMP_UPDATE_MODE:** CSI_HS_RCOMP_UPDATE_MODE: 00b = RCOMP is updated if the clock lane is in LP11 state. 01b = RCOMP is updated if all the data lanes are in LP11 state. 10b = RCOMP is updated immediately after calibration is completed, or the CSI[1-3]_HS_RCOMP_OVR_ENABLE bits are written to 1 by software. 11b = Reserved. |
| 20:19 | 0h<br>RW | **CSI_HS_TOGGLE_LIMIT_CREG_ENC:** CSI_HS_TOGGLE_LIMIT_CREG_ENC: HS state machine toggle limit. Number of times RCOMP state machine will toggle before exiting. 2'b00: 6 toggles; 2'b01: 4 toggles; 2'b10: 8 toggles; 2'b11: 10 toggles; |

| Bit Range | Default & Access | Description |
|---|---|---|
| 18:16 | 0h<br>RW | **CSI_HS_CALIB_LOOP_DELAY:** CSI_HS_CALIB_LOOP_DELAY: Delay after applying a new RCOMP value to the AFE, before sampling the count up/down input from the AFE. 0h=)50-53ns; 1h=)60ns; 2h=)70-72ns; 3h=)80-83ns; 4h=)90ns; 5h=)100-102ns; 6h=)125-128ns; 7h=)150ns. At the start of each RCOMP calibration cycle, the state machine waits for 8x this delay before starting to sample the count up/down signal. |
| 15:11 | 0h<br>RW | **RSVD_15_11:** Reserved |
| 10 | 0b<br>RW | **CSI3_HS_RCOMP_OVR_ENABLE:** CSI3_HS_RCOMP_OVR_ENABLE: If set, then the CSI_HS_RCOMP_OVRD field is used as the RCOMP value during the update cycle for CSI port 3. If clear, then the output of the RCOMP calibration engine (stored in CSI_RCOMP_CALIBRATION_VALUE field of IUNIT_RCOMP_STATUS register) is used as the RCOMP value during the update cycle for CSI port 3. |
| 9 | 0b<br>RW | **CSI2_HS_RCOMP_OVR_ENABLE:** CSI2_HS_RCOMP_OVR_ENABLE: If set, then the CSI_HS_RCOMP_OVRD field is used as the RCOMP value during the update cycle for CSI port 2. If clear, then the output of the RCOMP calibration engine (stored in CSI_RCOMP_CALIBRATION_VALUE field of IUNIT_RCOMP_STATUS register) is used as the RCOMP value during the update cycle for CSI port 2. |
| 8 | 0b<br>RW | **CSI1_HS_RCOMP_OVR_ENABLE:** CSI1_HS_RCOMP_OVR_ENABLE: If set, then the CSI_HS_RCOMP_OVRD field is used as the RCOMP value during the update cycle for CSI port 1. If clear, then the output of the RCOMP calibration engine (stored in CSI_RCOMP_CALIBRATION_VALUE field of IUNIT_RCOMP_STATUS register) is used as the RCOMP value during the update cycle for CSI port 1. |
| 7:1 | 0h<br>RW | **CSI_HS_RCOMP_OVR_CODE:** CSI_HS_RCOMP_OVR_CODE: Software defined value to use as the RCOMP value for CSI[1-3] ports if the CSI[1-3]_HS_RCOMP_OVR_ENABLE fields are set. |
| 0 | 1b<br>RW | **CSI_HS_RCOMP_ENABLE:** CSI_HS_RCOMP_ENABLE: Enable CSI HS RCOMP. (Note: This bit does not affect the initial RCOMP at the de-assertion of reset which is controlled by the fuse FB_disable_initial_RCOMP.) |

## 15.7.33 iunit_IUNIT_STATUS_type (IUNIT_STATUS)—Offset F8h



IUNIT Status Register

### Access Method

**Type:** PCI Configuration Register (Size: 32 bits)

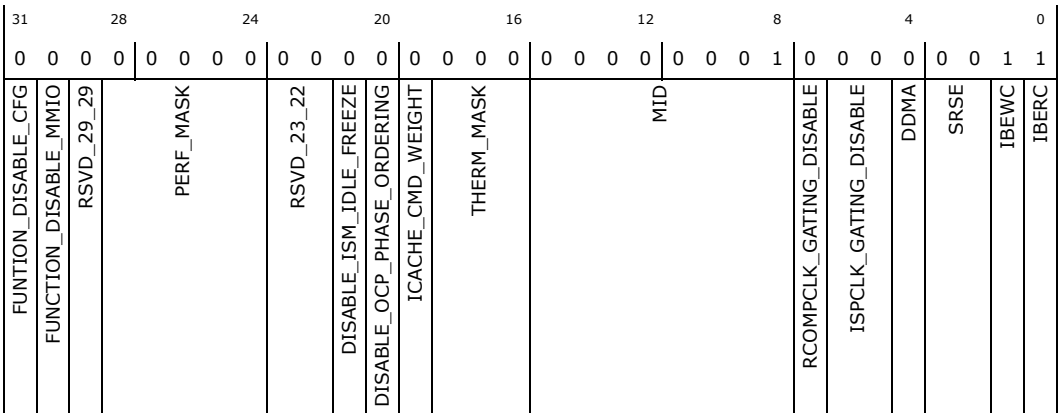
**IUNIT_STATUS:** [B:0, D:3, F:0] + F8h

**Default:** 0000EB01h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31:18 | 0h<br>RO | **RSVD_31_18:** Reserved |
| 17:13 | 07h<br>RO | **ISCLK:** Reflects the value of cck_isp_isclk_ratio_zcznfwh input pin. |
| 12:8 | 0Bh<br>RO | **CZCLK:** Reflects the value of cck_xxx_czclk_ratio_zcznfwh input pin. |

| Bit Range | Default & Access | Description |
|---|---|---|
| 7 | 0b<br>RO | **RSVD_7_7:** Reserved |
| 6:4 | 0h<br>RO | **TCGSM:** ISP trunk clock gating state machine. 0h = RUN_TRUNK_CLK; 1h = STOP_TRUNK_CLK; 2h = WAIT_FOR_RESUME; 3h = START_TRUNK_CLK; 4h = WAIT_FOR_LOCAL_CLK_TO_START. The reset value will be RUN_TRUNK_CLK. If the FB_override_initial_clock_gating fuse is not set, then shortly after reset, the value of this register will automatically change to STOP_TRUNK_CLK. |
| 3 | 0b<br>RO | **RSVD_3_3:** Reserved |
| 2:1 | 0h<br>RO | **LCGSM:** ISP local clock gating state machine. 0h = RUN_LOCAL_CLK; 1h = WAIT_FOR_FIFO_EMPTY; 2h = STOP_LOCAL_CLK. The reset value will be RUN_LOCAL_CLK. If the FB_override_initial_clock_gating fuse is not set, then shortly after reset, the value of this register will automatically change to STOP_LOCAL_CLK. |
| 0 | 1b<br>RO | **ISP_BUSY:** ISP_BUSY: 1 = ISP is busy; 0 = ISP is idle. |

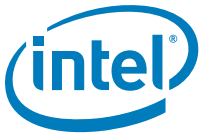
## 15.7.34 iunit_IUNIT_CONTROL_type (IUNIT_CONTROL)—Offset FCh



IUNIT Control Register

### Access Method

**Type:** PCI Configuration Register (Size: 32 bits)

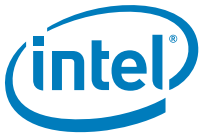


**IUNIT_CONTROL:** [B:0, D:3, F:0] + FCh

**Default:** 00000103h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31 | 0b<br>RW | **FUNTION_DISABLE_CFG:** FUNCTION_DISABLE_CFG: When set, the IUNIT stops accepting any new Configuration cycle requests on the IOSF Primary bus including any new configuration cycle requests to clear this bit. Both legacy and MSI interrupts are disabled as well. |
| 30 | 0b<br>RW | **FUNCTION_DISABLE_MMIO:** FUNCTION_DISABLE_MMIO: When set, the IUNIT stops accepting any new MMIO access requests on the IOSF Primary bus. |
| 29 | 0b<br>RW | **RSVD_29_29:** Reserved |

| Bit Range | Default & Access | Description |
|---|---|---|
| 28:24 | 0h<br>RW | **PERF_MASK:** PERF_MASK: This field determines the amount of performance throttling applied to ispclk. The value of this field determines how many beat periods of ispclk are killed, where a beat period is defined as 16 ispclk cycles. A 16 cycle period was chosen to make the throttling independent of the actual clock ratio between ispclk and coreclk. Note that clock gating should be enabled when thermal throttling is enabled. |
| 23:22 | 0h<br>RW | **RSVD_23_22:** Reserved |
| 21 | 0h<br>RW | **DISABLE_ISM_IDLE_FREEZE:** DISABLE_ISM_IDLE_FREEZE: When IUNIT receive a RESET_WARN message from PUNIT, it will freeze the IOSF primary Idle State Machine (among other things), before sending an OK_TO_RESET message to PUNIT. If the DISABLE_ISM_IDLE_FREEZE bit is set, IUNIT will not freeze the ISM in the IDLE state as part of this reset sequence. |
| 20 | 0h<br>RW | **DISABLE_OCP_PHASE_ORDERING:** DISABLE_OCP_PHASE_ORDERING: By default, IUNIT will follow the OCP phase ordering protocol and wait until a write command is accepted before accepting the write data corresponding to that command. If the DISABLE_OCP_PHASE_ORDERING bit is set, the IUNIT wrapper will accept the write data independent of the write command. |
| 19 | 0h<br>RW | **ICACHE_CMD_WEIGHT:** ICACHE_CMD_WEIGHT: 0b = Requests from the OCP master port sending Icache miss traffic will win arbitration over requests from the OCP master port that sends pixel data traffic. 1b = Requests from the two OCP master interfaces will be accepted in a round robin fashion. |
| 18:16 | 0h<br>RW | **THERM_MASK:** THERM_MASK: This field determines the amount of thermal throttling applied to ispclk. The value of this field determines how many beat periods of ispclk are killed, where a beat period is defined as 16 ispclk cycles. A 16 cycle period was chosen to make the throttling independent of the actual clock ratio between ispclk and coreclk. 000 = No throttling; 001 = 12.5% throttling; 010 = 25% throttling; 011 = 37.5% throttling; 100 = 50% throttling; 101 = 62.5% throttling; 110 = 75% throttling; 111 = 87.5% throttling; |
| 15:8 | 01h<br>RW | **MID:** MIN_IDLE_DELAY: Minimum wait time after the rising edge of idle, before the clock gating state machine will start the sequence to gate ispclk. Range is 0 to 130 usec. Unit is 0.512 usec. Reset value of 8'h1 indicates MID = 0.512 usec. |
| 7 | 0b<br>RW | **RCOMPCLK_GATING_DISABLE:** 1 = Disable clock gating for rcompclk. 0 = Enable clock gating for rcompclk. Note: All clock gating is disabled by hardware while reset is asserted, regardless of the state of this field. |
| 6:5 | 00b<br>RW | **ISPCLK_GATING_DISABLE:** ISPCLK_GATING_DISABLE: 11 = Disable local clock gating and trunk clock gating for ispclk.; 10 = Enable local clock gating for ispclk, but disable trunk clock gating.; 01 = Reserved; 00 = Enable local clock gating and trunk clock gating for ispclk. Note: All clock gating is disabled by hardware while reset is asserted, regardless of the state of this field. |
| 4 | 0b<br>RW | **DDMA:** 1 = Disable DMA. Stop sending any requests on the IB PFI port. 0 = Enable DMA. IB PFI port operates normally. |
| 3:2 | 0h<br>RW | **SRSE:** SOFT_RESET_SEQUENCE_ENABLE: If SRSE=2b00: When an IUNIT_RESET_WARN message is received from PUNIT, IUNIT will a) stop accepting requests on the IOSF primary interface, b) stop accepting new requests from the OCP master interface, c) wait until read data from all earlier read requests received from the OCP master interface have been returned by SSA, d) wait until SSA reads data for all earlier PFI write requests, and e) wait for all DPHY lanes to enter stop state (LP11), and then f) send an IUNIT_OK_TO_RESET posted message to PUNIT. If SRSE=2b01: When an IUNIT_RESET_WARN message is received from PUNIT, IUNIT will a) stop accepting requests on the IOSF primary interface, b) stop accepting new requests from the OCP master interface, c) wait until read data from all earlier read requests received from the OCP master interface have been returned by SSA, d) wait until SSA reads data for all earlier PFI write requests, and then e) send an IUNIT_OK_TO_RESET posted message to PUNIT. If SRSE=2b10: When an IUNIT_RESET_WARN message is received from PUNIT, IUNIT will wait for all DPHY lanes to enter stop state (LP11), and then send an IUNIT_OK_TO_RESET posted message to PUNIT. If SRSE=2b11: When an IUNIT_RESET_WARN message is received from PUNIT, IUNIT will immediately send an IUINT_OK_TO_RESET posted message to PUNIT. |



| Bit Range | Default & Access | Description |
|---|---|---|
| 1 | 1b<br>RW | **IBEWC:** IB_ENABLE_WRITE_COMBINING: When set, enables the combining of adjacent 32-byte write requests to the same cache line. When cleared, each 32-byte write request is sent as a separate request on the IB interface. |
| 0 | 1b<br>RW | **IBERC:** IB_ENABLE_READ_COMBINING: When set, enables the combining of adjacent 32-byte read requests to the same cache line. When cleared, each 32-byte read request is sent as a separate request on the IB interface. |

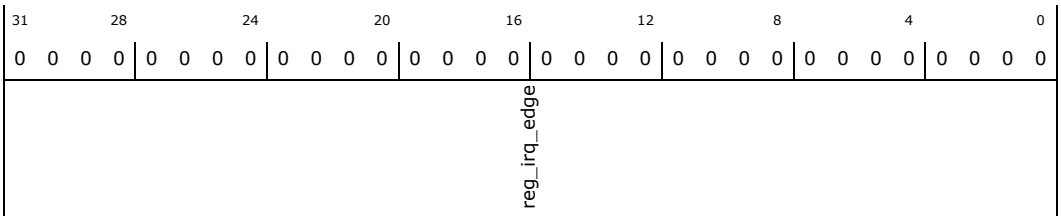
## 15.8.40 reg_gpd_irq_ctrl_reg_irq_edge_type (gpd_irq_ctrl_reg_irq_edge)—Offset 500h



### Access Method

**Type:** Memory Mapped I/O Register (Size: 32 bits)

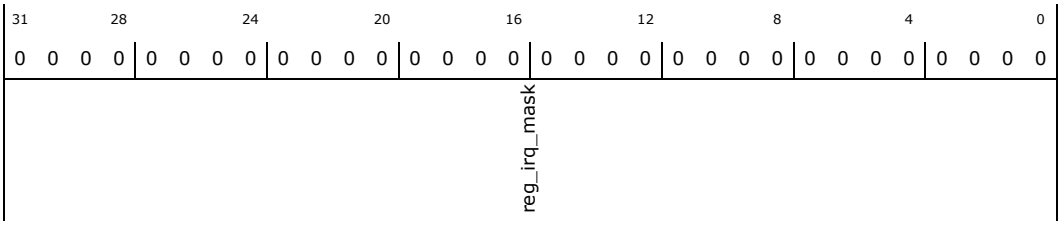
**gpd_irq_ctrl_reg_irq_edge:** [ISPMMADR] + 500h

**ISPMMADR Type:** PCI Configuration Register (Size: 32 bits)
**ISPMMADR Reference:** [B:0, D:3, F:0] + 10h

**Default:** 00000000h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31:0 | 0h<br>RW | **reg_irq_edge:** indicates for each bit whether an interrupt request should be generated on a falling edge (value='0') or a rising edge (value='1'). |

## 15.8.41 reg_gpd_irq_ctrl_reg_irq_mask_type (gpd_irq_ctrl_reg_irq_mask)—Offset 504h



### Access Method

**Type:** Memory Mapped I/O Register (Size: 32 bits)

**gpd_irq_ctrl_reg_irq_mask:** [ISPMMADR] + 504h

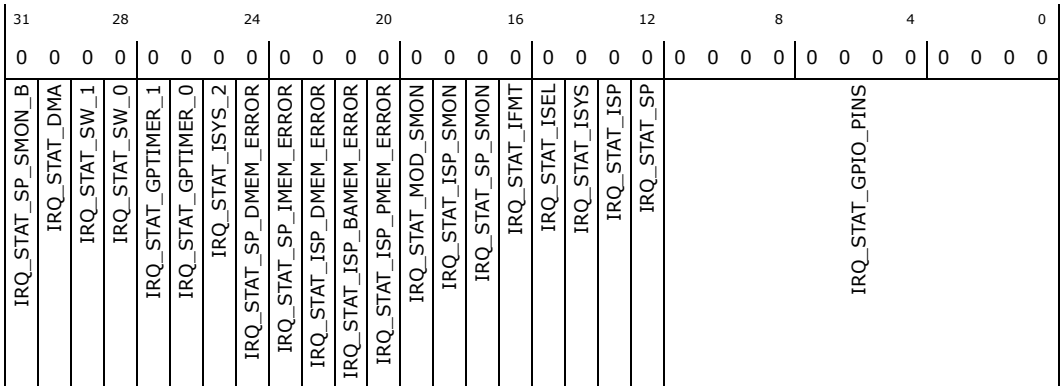
**ISPMMADR Type:** PCI Configuration Register (Size: 32 bits)
**ISPMMADR Reference:** [B:0, D:3, F:0] + 10h

**Default:** 00000000h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31:0 | 0h<br>RW | **reg_irq_mask:** indicates for each bit of irq_di whether it can generate an interrupt request (value='1') or not (value='0'). Setting will affect reg_irq_value as well as IRQ output pin |

## 15.8.42 reg_gpd_irq_ctrl_reg_irq_status_type (gpd_irq_ctrl_reg_irq_status)—Offset 508h

Indicates for each bit whether a non-masked interrupt has been generated (value='1'). Can be cleared by writing a '1' into the the corresponding bit of the req_irq_clear register.



### Access Method

**Type:** Memory Mapped I/O Register (Size: 32 bits)

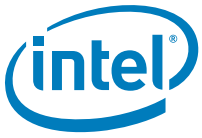
# 16 Storage Control Cluster (eMMC, SDIO, SD Card)

The Storage Control Cluster (SCC) consists of SDIO, SD Card and eMMC controllers to support mass storage and IO devices.

- One eMMC 4.5 interface
- One SD Card 3.0 interface
- One SDIO 3.0 interface for SDIO-based WIFI

***Note:*** All units in the SCC support both PCI mode and ACPI mode of operation. A level shifter may be needed on the platform for SDIO 3.0 compliance. An eMMC 4.41 controller also exists but shouldn't be used.

***Note:*** eMMC* 5.0 is functional and backward compatible on the Bay Trail platform for features included in eMMC 4.5, with no guarantees the performance is as good as eMMC* 4.5.



## 16.1 Signal Descriptions

See Chapter 2, "Physical Interfaces" for additional details.

The signal description table has the following headings:

- **Signal Name:** The name of the signal/pin
- **Direction**: The buffer direction can be either input, output, or I/O (bidirectional)
- **Platform Power**: The reference power plane.
- **Description**: A brief explanation of the signal's function

### Table 181. eMMC Signals

| Signal Name | Direction Power | Description |
|---|---|---|
| **MMC1_CLK** | O<br>V1P8S | **eMMC Clock**<br>The frequency may vary between 400 kHz and 200 MHz. |
| **MMC1_D[7:0]** | I/O<br>V1P8S | **eMMC Port Data bits 0 to 7**<br>Bidirectional port used to transfer data to and from eMMC device.<br>By default, after power up or reset, only D[0] is used for data transfer. A wider data bus can be configured for data transfer, using either D[0]-D[3] or D[0]-D[7], by the MultiMedia Card controller.<br>The MultiMedia Card includes internal pull-ups for data lines D[1]-D[7]. Immediately after entering the 4-bit mode, the card disconnects the internal pull ups of lines D[1], D[2], and D[3]. Correspondingly, immediately after entering to the 8-bit mode the card disconnects the internal pull-ups of lines D[1]-D[7]. |

The default voltage (3.3 V) is requested when this signal is driven low. 1.8 V is requested when this signal is high. This voltage change applies to the SD3_V1P8V3P3_S3 (VSDIO) rail on the SoC. |
| **SD3_RCOMP** | - | **SD Card RCOMP**<br>This signal is used for pre-driver slew rate compensation. |
| **SD3_WP** | I<br>V1P8S | **SD Card Write Protect**<br>Active high to protect from write. |
| **SD3_PWREN#** | O<br>V1P8S | **SD Card Power Enable**<br>This signal is used to enable power on a SD device. |

# 16.2 Features

## 16.2.1 eMMC Interface Features

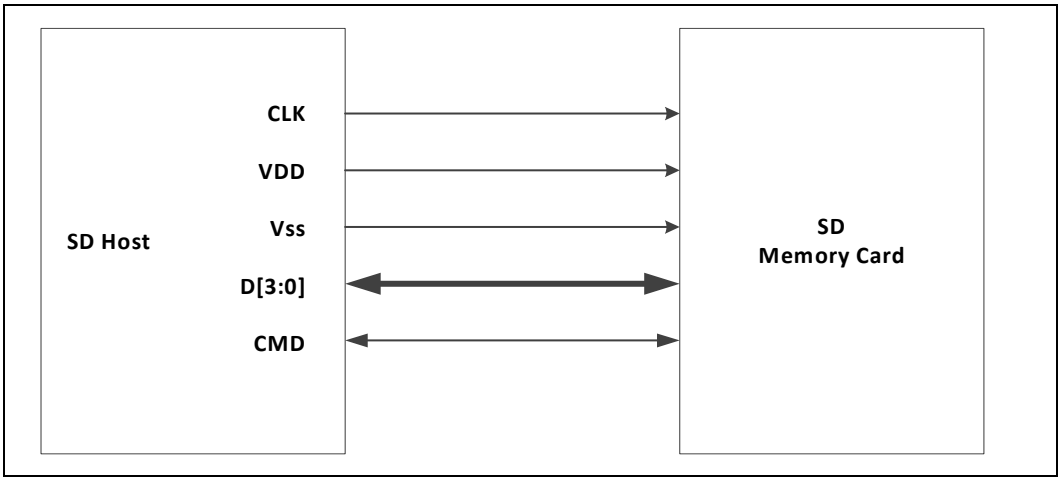
- eMMC 4.5 controller supported
- Transfers the data in 1 bit, 4 bit and 8 bit modes.
- Transfers data in the following speed classes: Baseline (1, 4, 8 bit up to 25Mhz), HS SDR/DDR (4, 8 bit up to 50Mhz) and HS200 (4, 8 bit up to 200MHz - 4.5 controller only)
- Cyclic Redundancy Check CRC7 for command and CRC16 for data integrity.
- Supports MMC Plus and MMC mobile.
- Supports both round-robin and priority-based arbitration for transmit operation.
- Run-time configurabilty of channel ID bits.

## 16.2.2 SDIO/SD Card Interface Features

- Up to 400Mbits per second data rate using 4 parallel data lines.
- Transfers the data in 1 bit and 4 bit SD modes and SPI mode.
- Transfers the data in following UHS-I modes: HS ,DDR50 and SDR12/25.
- Cyclic Redundancy Check CRC7 for command and CRC16 for data integrity.
- Designed to work with I/O cards, Read-only cards and Read/Write cards.
- Supports Read wait Control, Suspend/Resume operation.

***Note:*** SDIO only validated with WIFI devices.

## 16.2.3 Storage Interfaces Overview



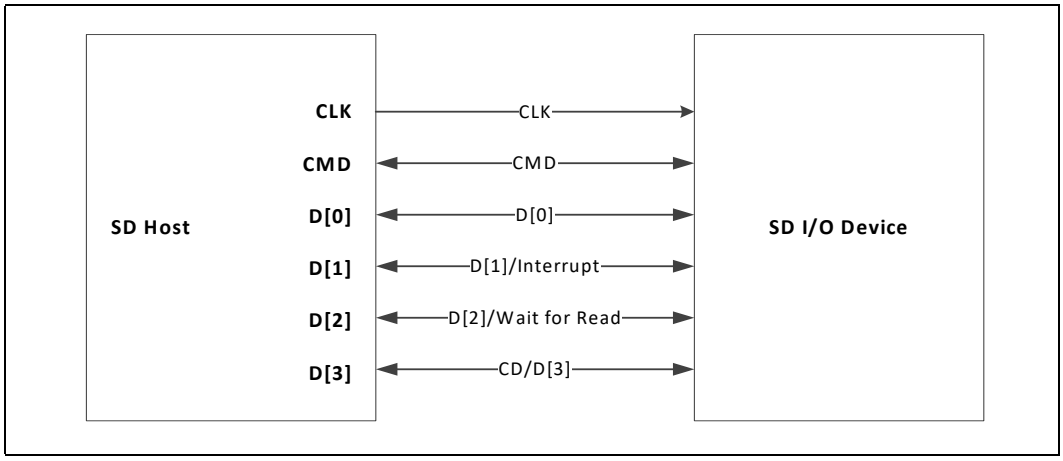
This section provides a very high level overview of the SD, SDIO, eMMC 4.5 specification. Refer to the SD and eMMC specifications for complete details.

### 16.2.3.1 SD Card 3.0 Bus Interface

The SD Card bus has a single master, single slaves (card), synchronous topology (refer to Figure 98). During initialization process commands are sent to the card, allowing the application to detect the card and assign logical addresses to the physical slot. All data communication in the Card Identification Mode uses the command line (CMD) only.

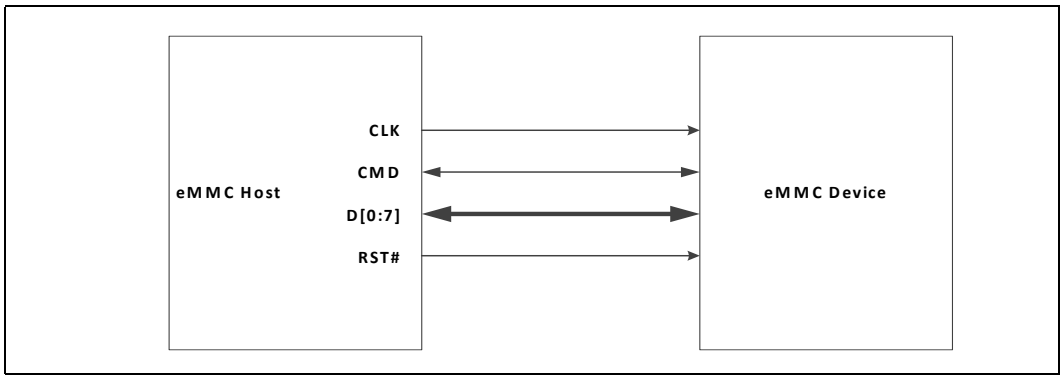
SD bus allows dynamic configuration of the number of data lines. After power up, by default, the SD Card will use only SD3_D[0] for data transfer. After initialization the host can change the bus width (number of active data lines). This feature allows easy trade off between hardware cost and system performance. Note that while DAT1-SD3_D[3:1] are not in use, the SoC will tri-state those signals.

**Figure 98. SD Memory Card Bus Topology**



### 16.2.3.2 SDIO 3.0 Interface

The SDIO interface is the very much like the SD card interface. The SoC supports one SDIO device for wireless devices only (no memory card support).



***Note:*** SDIO interface does not support WAKE function.

**Figure 99. SDIO Device Bus Topology**

### 16.2.3.3 eMMC4.5 Interface

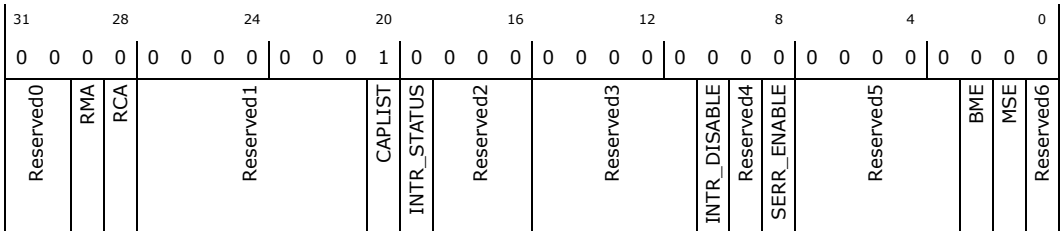
| 15:0 | 0000h<br>RO | **Vendor ID (VENDORID):** Vendor ID is a unique ID provided by PCI SIG which identifies the manufacturer of the device. This is tied to a strap at the top level. |



## 16.5.2 Status and Command Register (STATUSCOMMAND)—Offset 4h

### Access Method

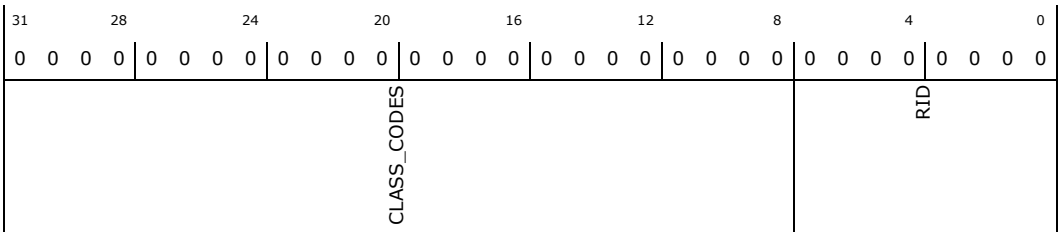
**Type:** PCI Configuration Register (Size: 32 bits)

**Offset:** [B:0, D:17, F:0] + 4h

**Default:** 00100000h

| Bit Range | Default & Access | Field Name (ID): Description |
|---|---|---|
| 31:30 | 0h<br>RO | **Reserved0:** Reserved. |
| 29 | 0h<br>RW/1C | **Received Master Abort (RMA):** If the completion status received from IOSF is UR, Bridge sets this bit. S/W writes a '1' to this bit to clear it. This bit will not be set for the Fabric port. This bit is not used for the Fabric Port |
| 28 | 0h<br>RW/1C | **Received Target Abort (RCA):** If the completion status received from IOSF is CA, Bridge sets this bit. S/W writes a 1 to this bit to clear it. This bit will not be set for the fabric port. This bit is not used for the Fabric Port |
| 27:21 | 00h<br>RO | **Reserved1:** Reserved. |
| 20 | 1h<br>RO | **Capabilities List (CAPLIST):** Hardwired to 1. Indicates that the controller contains a capabilities pointer list. The first item is pointed to by looking at configuration offset 34h. If PM capability is not required then this bit should be tied to 0. |
| 19 | 0h<br>RO | **Interrupt Status (INTR_STATUS):** This bit reflects state of interrupt in the device. Only when the Interrupt Disable bit in the command register is a 0 and this Interrupt Status bit is a 1, will the device's/function's INTx# signal be asserted. Setting the Interrupt Disable bit to a 1 has no effect on the state of this bit. This bit reflects Legacy interrupt status. |
| 18:16 | 0h<br>RO | **Reserved2:** Reserved. |
| 15:11 | 00h<br>RO | **Reserved3:** Reserved. |
| 10 | 0h<br>RW | **Interrupt Disable (INTR_DISABLE):** Setting this bit disables INTx assertion from Bridge. The interrupt disabled is legacy INTx# interrupt; i.e., Bridge does not send Interrupt Assert message through the IOSF SideBand Channel. Reset value of this bit is 0. |
| 9 | 0h<br>RO | **Reserved4:** Reserved. |

| Bit Range | Default & Access | Field Name (ID): Description |
|---|---|---|
| 8 | 0h<br>RW | **SERR# Enable (SERR_ENABLE):** This bit controls the sending of DO_SERR messages on IOSF SB. |
| 7:3 | 00h<br>RO | **Reserved5:** Reserved. |
| 2 | 0h<br>RW | **Bus Master Enable (BME):** If this bit is 0, Bridge does not generate any new upstream transaction on IOSF as a master. Reset value of this bit is 0. |
| 1 | 0h<br>RW | **Memory Space Enable (MSE):** This bit controls Bridges response to downstream memory accesses. When set, accesses to the memory space of the device are enabled. Reset value of this bit is 0. |
| 0 | 0h<br>RO | **Reserved6:** Reserved. |



## 16.5.3 Revision ID and Class Code Register (REVCLASSCODE)—Offset 8h

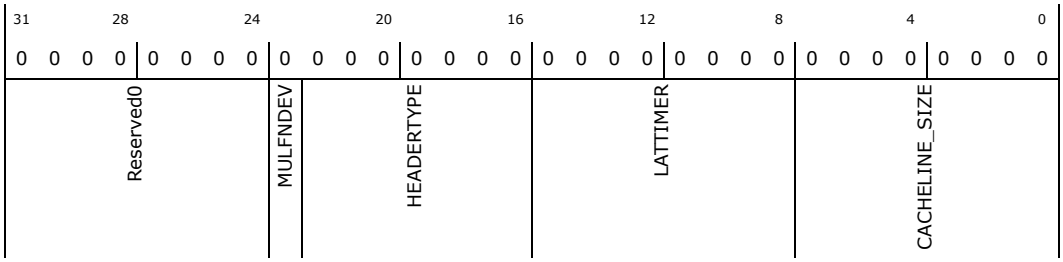
### Access Method

**Type:** PCI Configuration Register (Size: 32 bits)

**Offset:** [B:0, D:17, F:0] + 8h

**Default:** 00000000h

| Bit Range | Default & Access | Field Name (ID): Description |
|---|---|---|
| 31:8 | 000000h<br>RO | **Class Code (CLASS_CODES):** This register is read-only and is used to identify the generic function of the device and, in some cases, a specific register level programming interface. The register is broken into three byte size fields. The upper byte (at offset 0Bh) is a base class code which broadly classifies the type of function the device performs. The middle byte (at offset 0Ah) is a sub-class code which identifies more specifically the function of the device. The lower byte (at offset 09h) identifies a specific register-level programming interface (if any) so that device independent software can interact with the device. This register is tied to a strap at the top level. |
| 7:0 | 00h<br>RO | **Revision ID (RID):** Identifies the revision of a particular AHB device. This is tied to a strap at the top level. |



## 16.5.4 Cache Line Size, Latency Timer, and Header Type Register (CLLATHEADERBIST)—Offset Ch

### Access Method

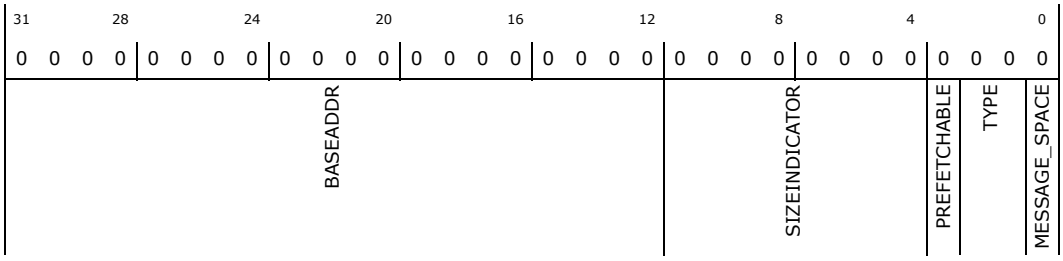
**Type:** PCI Configuration Register (Size: 32 bits)

**Offset:** [B:0, D:17, F:0] + Ch

**Default:** 00000000h

| Bit Range | Default & Access | Field Name (ID): Description |
|---|---|---|
| 31:24 | 00h<br>RO | **Reserved0:** Reserved. |
| 23 | 0h<br>RO | **Multifunction Device (MULFNDEV):** This bit is always 0 for non-fabric ports. For fabric ports it is driven from the fabric_mult_function strap. A value of 1 indicates a multifunction device; a value of 0 indicates a single function device. |
| 22:16 | 00h<br>RO | **Header Type (HEADERTYPE):** Implements Type 0 Configuration header. |
| 15:8 | 00h<br>RO | **Latency Timer (LATTIMER):** Doesnt apply to PCI Express. Hardwired to 00h. |
| 7:0 | 00h<br>RW | **Cache Line Size (CACHELINE_SIZE):** Doesnt apply to PCI Express. PCI Express spec requires this to be implemented as a R/W register but has no functional impact on the AHB Device connected. |

## 16.5.5 Base Address Register (BAR)—Offset 10h



Each AHB device is a single function device with only a single BAR associated with it. Bits 31:4 indicate the Base Address register. Power-up software can determine how much address space the AHB Device requires by writing a value of all 1's to the register and then reading the value back. Bridge will return 0's in all don't-care address bits, effectively specifying the address space required. Unimplemented Base Address registers are hardwired to zero. This is the Size Indicator Read only bits of the register.

### Access Method

**Type:** PCI Configuration Register (Size: 32 bits)

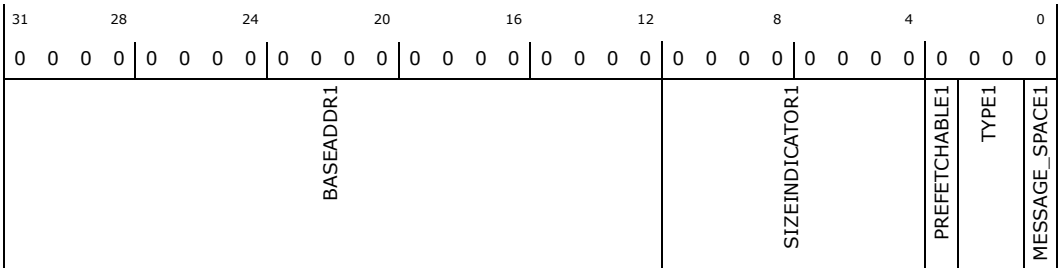
**Offset:** [B:0, D:17, F:0] + 10h

**Default:** 00000000h

| Bit Range | Default & Access | Field Name (ID): Description |
|---|---|---|
| 31:12 | 00000h<br>RW | **Base Address (BASEADDR):** Base address of the AHB device memory space. Taken from Strap values as 1s. |

| Bit Range | Default & Access | Field Name (ID): Description |
|---|---|---|
| 11:4 | 00h<br>RO | **Size Indicator (Read Only) (SIZEINDICATOR):** Always returns zero. The size of this register depends on the size of the Memory space. This size is determined by a top level of STRAP values as 0s. |
| 3 | 0h<br>RO | **Prefetchable (PREFETCHABLE):** Indicates that this bar is not prefetchable. |
| 2:1 | 0h<br>RO | **Type (TYPE):** '00' indicates that the BAR lies in 32 bit address range. |
| 0 | 0h<br>RO | **Memory Space Indicator (MESSAGE_SPACE):** 0 Indicates that this BAR is present in the memory space. |

## 16.5.6 Base Address Register 1 (BAR1)—Offset 14h



Memory accesses to BAR1 region access the PCI configuration space for the LPIO device. BAR1 region is always 4K. However SW accesses through BAR1 should only access the regular PCI configuration space. BAR1 memory accesses which do not access a defined PCI configuration register are treated as accesses to a reserved register.

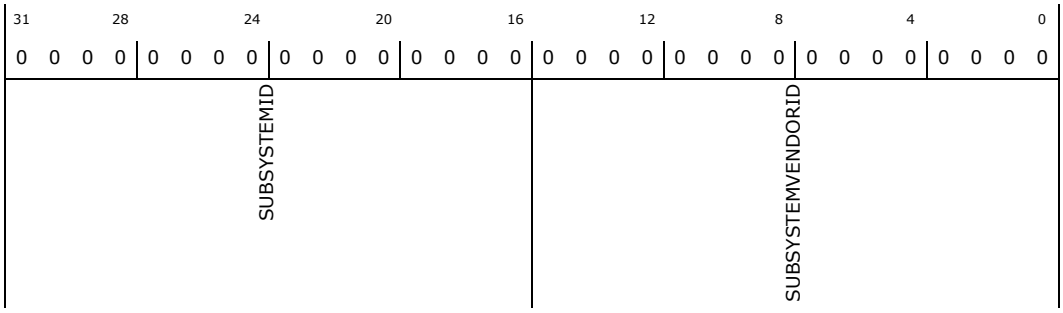
### Access Method

**Type:** PCI Configuration Register (Size: 32 bits)

**Offset:** [B:0, D:17, F:0] + 14h

**Default:** 00000000h

| Bit Range | Default & Access | Field Name (ID): Description |
|---|---|---|
| 31:12 | 00000h<br>RW | **Base Address Register1 (BASEADDR1):** This field is present if BAR1 is enabled through private config space. If this register is disabled then this is RO and always returns 0. |
| 11:4 | 00h<br>RO | **Size Indicator1 (SIZEINDICATOR1):** Always will be zero as minimum size is 4K. |
| 3 | 0h<br>RO | **Prefetchable (PREFETCHABLE1):** Indicates that this bar is not prefetchable. |
| 2:1 | 0h<br>RO | **Type (TYPE1):** '00' indicates that the BAR lies in 32 bit address range. |
| 0 | 0h<br>RO | **Memory Space Indicator (MESSAGE_SPACE1):** 0 Indicates that this BAR is present in the memory space. |



## 16.5.7 Subsystem Vendor ID and Subsystem ID Register (SUBSYSTEMID)—Offset 2Ch

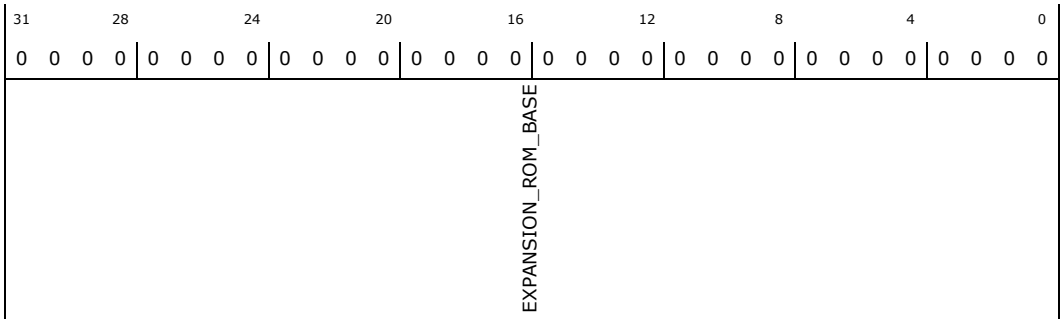
### Access Method

**Type:** PCI Configuration Register (Size: 32 bits)

**Offset:** [B:0, D:17, F:0] + 2Ch

**Default:** 00000000h

| Bit Range | Default & Access | Field Name (ID): Description |
|---|---|---|
| 31:16 | 0000h RW/O | **Subsystem ID (SUBSYSTEMID):** This register should be implemented for any function that could be instantiated more than once in a given system. Th is register makes it possible for the operating environment to distinguish one audio subsystem from the other. This is a Read Write Once register. |
| 15:0 | 0000h RW/O | **Subsystem Vendor ID (SUBSYSTEMVENDORID):** This register should be implemented for any function that could be instantiated more than once in a given system. This register enables the operating environment to distinguish one subsystem from the other. This is a Read Write Once register. |



## 16.5.8 Expansion ROM Base Address Register (EXPANSION_ROM_BASEADDR)—Offset 30h

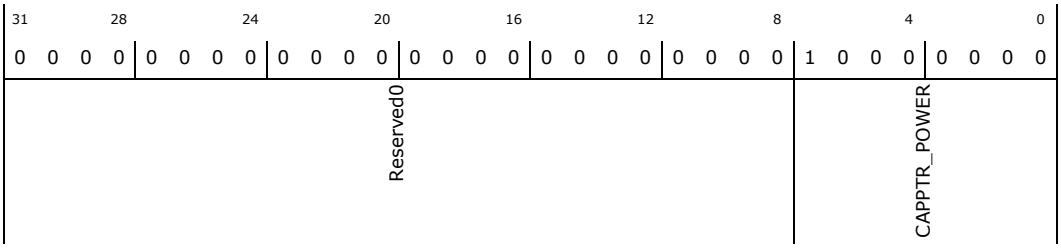
### Access Method

**Type:** PCI Configuration Register (Size: 32 bits)

**Offset:** [B:0, D:17, F:0] + 30h

**Default:** 00000000h

| Bit Range | Default & Access | Field Name (ID): Description |
|---|---|---|
| 31:0 | 00000000h RO | **Expansion ROM Base Address (EXPANSION_ROM_BASE):** Value of all 0s indicates no support for Expansion ROM. |



## 16.5.9 Capabilities Pointer Register (CAPABILITYPTR)—Offset 34h

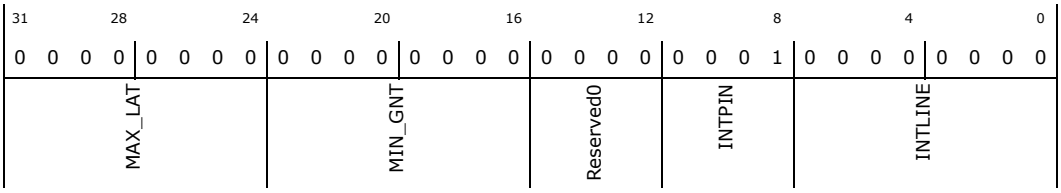
### Access Method

**Type:** PCI Configuration Register (Size: 32 bits)

**Offset:** [B:0, D:17, F:0] + 34h

**Default:** 00000080h

| Bit Range | Default & Access | Field Name (ID): Description |
|---|---|---|
| 31:8 | 000000h RO | **Reserved0:** Reserved. |
| 7:0 | 80h RO | **Capabilities Pointer (CAPPTR_POWER):** Indicates what the next capability is. This capability can be programmed to be PM Capability (0x80) if PM Capability is enabled in SB. When PM capability is disabled, this register is 00h. |



## 16.5.10 Interrupt Register (INTERRUPTREG)—Offset 3Ch

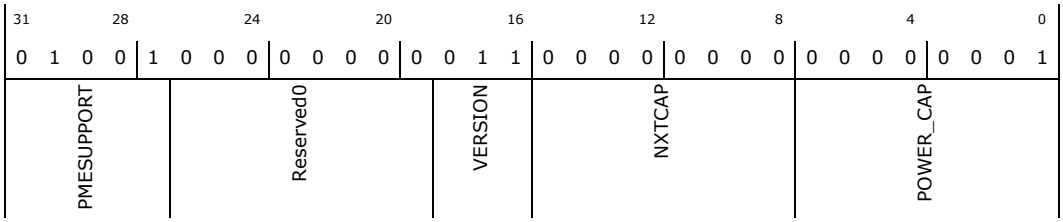
### Access Method

**Type:** PCI Configuration Register (Size: 32 bits)

**Offset:** [B:0, D:17, F:0] + 3Ch

**Default:** 00000100h

| Bit Range | Default & Access | Field Name (ID): Description |
|---|---|---|
| 31:24 | 00h RO | **Max_Lat (MAX_LAT):** Value of 0 indicates that the device has no major requirements for the settings of latency timers. |
| 23:16 | 00h RO | **Min_Gnt (MIN_GNT):** Value of 0 indicates that the device has no major requirements for the settings of latency timers. |
| 15:12 | 0h RO | **Reserved0:** Reserved. |
| 11:8 | 1h RO | **Interrupt Pin (INTPIN):** Each AHB IP on Bridge is a single function device. Hence Bridge only generates INTA on IOSF SB. The Fabric on AHB Bridge appears as a Multifunction device. Interrupt Pin Value in this register is reflected from the IPIN value in the private configuration space. |
| 7:0 | 00h RW | **Interrupt Line (INTLINE):** Bridge does not use this field directly. It is used to communicate to software the interrupt line that the interrupt pin is connected to. |



## 16.5.11 Power Management Capability ID Register (POWERCAPID)—Offset 80h

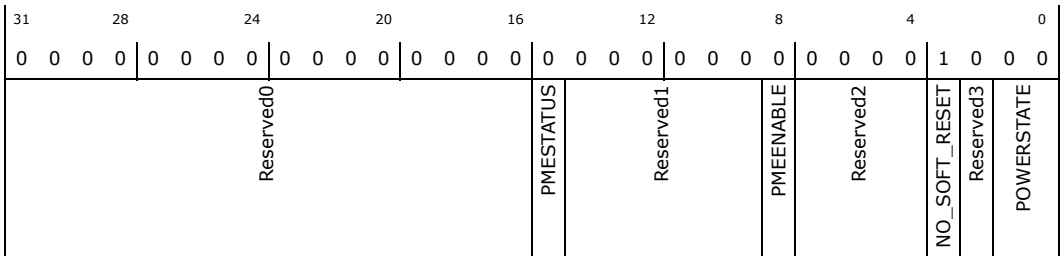
### Access Method

**Type:** PCI Configuration Register (Size: 32 bits)

**Offset:** [B:0, D:17, F:0] + 80h

**Default:** 48030001h

| Bit Range | Default & Access | Field Name (ID): Description |
|---|---|---|
| 31:27 | 09h<br>RO | **PME_Support (PMESUPPORT):** This 5-bit field indicates the power states in which the function may assert PME#. A value of 0b for any bit indicates that the function is not capable of asserting the PME# signal while in that power state.<br>bit(11) X XXX1b - PME# can be asserted from D0<br>bit(12) X XX1Xb - PME# can be asserted from D1. Bridge does not support this state.<br>This field is taken from the private configuration space PME_Support XORed with the PME_Support strap. |
| 26:19 | 00h<br>RO | **Reserved0:** Reserved. |
| 18:16 | 3h<br>RO | **Version (VERSION):** Indicates support for Revision 1.2 of the PCI Power Management Specification. |
| 15:8 | 00h<br>RO | **Next Capability (NXTCAP):** Points to the next capability structure. This points to NULL. |
| 7:0 | 01h<br>RO | **Power Management Capability (POWER_CAP):** Indicates this is power management capability. |



## 16.5.12 Power Management Control and Status Register (PMECTRLSTATUS)—Offset 84h

### Access Method

**Type:** PCI Configuration Register (Size: 32 bits)

**Offset:** [B:0, D:17, F:0] + 84h

**Default:** 00000008h

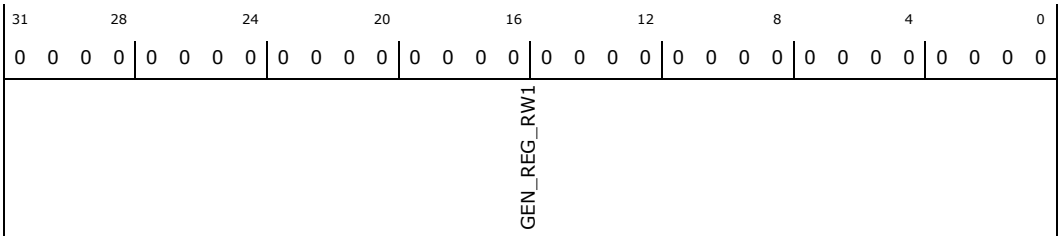
| 7:4 | 0h<br>RO | **Reserved2:** Reserved. |
| 3 | 1h<br>RO | **No Soft Reset (NO_SOFT_RESET):** This bit indicates that devices transitioning from D3hot to D0 because of PowerState commands do not perform an internal reset. Configuration Context is preserved. |
| 2 | 0h<br>RO | **Reserved3:** Reserved. |
| 1:0 | 0h<br>RW | **Power State (POWERSTATE):** This field is used both to determine the current power state of the AHB IP and to set a new power state. The values are:<br>00 = D0 state<br>11 = D3HOT state<br>Others = Reserved<br>Notes: If software attempts to write a value of 01b or 10b in to this field, the write operation must complete normally; however, the data is discarded and no state change occurs. When in the D3HOT states, interrupts are blocked. D3Hot will not be used for upstream decode on fabric ports. |



## 16.5.13 General Purpose Read Write Register1 (GEN_REGRW1)—Offset A0h

### Access Method

**Type:** PCI Configuration Register (Size: 32 bits)

**Offset:** [B:0, D:17, F:0] + A0h

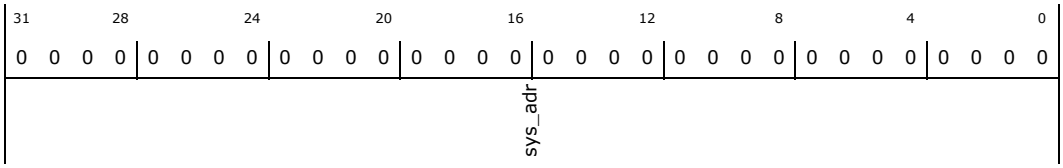
## 16.6.1 SDMA System Address / Argument 2 Register (SYS_ADR)—Offset 0h

This register contains the physical system memory address used for DMA transfers or the second argument for the Auto CMD23.



### Access Method

**Type:** Memory Mapped I/O Register (Size: 32 bits)

**Offset:** [BAR] + 0h

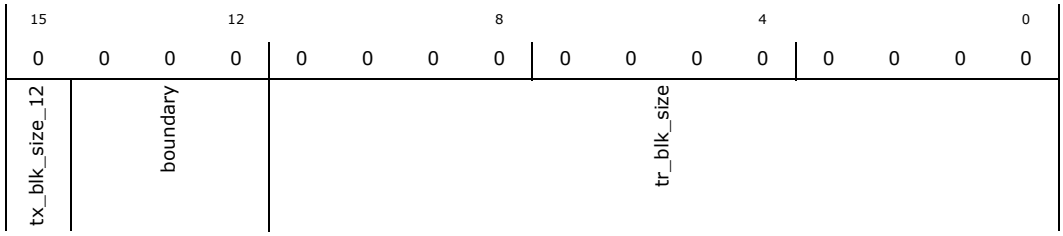
**BAR Type:** PCI Configuration Register (Size: 32 bits)
**BAR Reference:** [B:0, D:17, F:0] + 10h

**Default:** 00000000h

| Bit Range | Default & Access | Field Name (ID): Description |
|---|---|---|
| 31:0 | 00000000h<br>RW | **SDMA System Address (sys_adr): (1) SDMA System Address**<br>This register contains the system memory address for a SDMA transfer. When the Host Controller stops a SDMA transfer, this register shall point to the system address of the next contiguous data position. It can be accessed only if no transaction is executing (i.e., after a transaction has stopped). Read operations during transfers may return an invalid value.<br>The Host Driver shall initialize this register before starting a SDMA transaction. After SDMA has stopped, the next system address of the next contiguous data position can be read from this register.<br>The SDMA transfer waits at each boundary specified by the Host SDMA Buffer Boundary in the Block Size register. The Host Controller generates a DMA Interrupt to request the Host Driver to update this register. The Host Driver sets the next system address of the next data position to this register.<br>When the uppermost byte of this register (003h) is written, the Host Controller restarts the SDMA transfer.<br>When restarting SDMA by the Resume command or by setting Continue Request in the Block Gap Control register, the Host Controller shall start at the next contiguous address stored here in the SDMA System Address register. ADMA does not use this register. **(2) Argument 2**<br>This register is used with the Auto CMD23 to set a 32-bit block count value to the argument of the CMD23 while executing Auto CMD23.<br>If Auto CMD23 is used with ADMA, the full 32-bit block count value can be used. If Auto CMD23 is used without AMDA, the available block count value is limited by the Block Count register. 65535 blocks is the maximum value in this case. |

## 16.6.2 Block Size Register (BLK_SIZE)—Offset 4h

This register is used to configure the number of bytes in a data block.



### Access Method

**Type:** Memory Mapped I/O Register (Size: 16 bits)

**Offset:** [BAR] + 4h

**BAR Type:** PCI Configuration Register (Size: 32 bits)

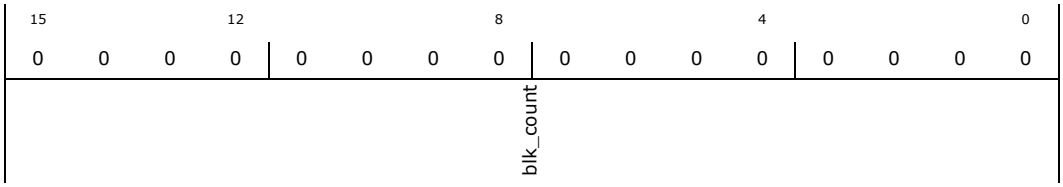
| 14:12 | 000b<br>RW | **Host SDMA Buffer Boundary (boundary):** The large contiguous memory space may not be available in the virtual memory system. To perform long SDMA transfer, SDMA System Address register shall be updated at every system memory boundary during SDMA transfer. These bits specify the size of contiguous buffer in the system memory. The SDMA transfer shall wait at each boundary specified by these fields and the Host Controller generates the DMA Interrupt to request the Host Driver to update the SDMA System Address register. At the end of transfer, the Host Controller may issue or may not issue DMA Interrupt. In particular, DMA Interrupt shall not be issued after Transfer Complete Interrupt is issued. In case of this register is set to 0 (buffer size = 4K bytes), lower 12-bit of byte address points data in the contiguous buffer and the upper 20-bit points the location of the buffer in the system memory. The SDMA transfer stops when the Host Controller detects carry out of the address from bit 11 to 12. These bits shall be supported when the SDMA Support in the Capabilities register is set to 1 and this function is active when the DMA Enable in the Transfer Mode register is set to 1. ADMA does not use this register.<br>• 000b = 4K bytes (Detects A11 carry out)<br>• 001b = 8K bytes (Detects A12 carry out)<br>• 010b = 16K Bytes (Detects A13 carry out)<br>• 011b = 32K Bytes (Detects A14 carry out)<br>• 100b = 64K bytes (Detects A15 carry out)<br>• 101b = 128K Bytes (Detects A16 carry out)<br>• 110b = 256K Bytes (Detects A17 carry out)<br>• 111b = 512K Bytes (Detects A18 carry out) |

Values ranging from 1 up to the maximum buffer size can be set. In case of memory, it shall be set up to 512 bytes (Refer to Implementation Note in Section 1.7.2 *Determining Buffer Block Length*). It can be accessed only if no transaction is executing (i.e., after a transaction has stopped). Read operations during transfers may return an invalid value, and write operations shall be ignored.<br>• 0800h = 2048 Bytes<br>• . . .<br>• 0200h = 512 Bytes<br>• 01FFh = 511 Bytes<br>• . . .<br>• 0004h = 4 Bytes<br>• 0003h = 3 Bytes<br>• 0002h = 2 Bytes<br>• 0001h = 1 Byte<br>• 0000h = No data transfer |

## 16.6.3 Block Count Register (BLK_COUNT)—Offset 6h

This register is used to configure the number of data blocks.



### Access Method

**Type:** Memory Mapped I/O Register (Size: 16 bits)

**Offset:** [BAR] + 6h

**BAR Type:** PCI Configuration Register (Size: 32 bits)
**BAR Reference:** [B:0, D:17, F:0] + 10h

**Default:** 0000h

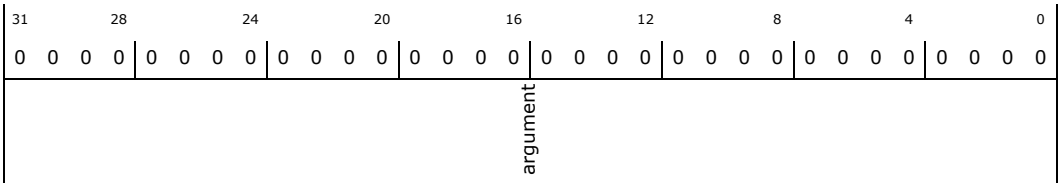
|---|---|---|
| 15:0 | 0000h<br>RW | **Blocks Count For Current Transfer (blk_count):** This register is enabled when Block Count Enable in the Transfer Mode register is set to 1, and is valid only for multiple block transfers. The Host Driver shall set this register to a value between 1 and the maximum block count. The HC decrements the block count after each block transfer, and stops when the count reaches zero. Setting the block count to 0 results in no data blocks being transferred. This register should be accessed only when no transaction is executing (i.e., after transactions are stopped). During data transfer, read operations on this register may return an invalid value and write operations are ignored. When saving transfer context as a result of a Suspend command, the number of blocks yet to be transferred can be determined by reading this register. When restoring transfer context prior to issuing a Resume command, the HD shall restore the previously saved block count.<br>• 0000h = Stop Count<br>• 0001h = 1 block<br>• 0002h = 2 blocks<br>• . . .<br>• FFFFh = 65535 blocks |

## 16.6.4 Argument 1 Register (ARGUMENT)—Offset 8h

This register contains the SD Command Argument.



### Access Method

**Type:** Memory Mapped I/O Register (Size: 32 bits)

**Offset:** [BAR] + 8h

**BAR Type:** PCI Configuration Register (Size: 32 bits)
**BAR Reference:** [B:0, D:17, F:0] + 10h

**Default:** 00000000h

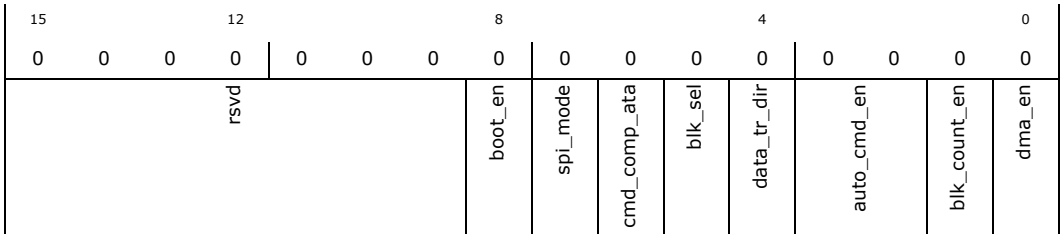
## 16.6.5 Transfer Mode Register (TX_MODE)—Offset Ch

This register is used to control the operation of data transfers. The Host Driver shall set this register before issuing a command which transfers data (Refer to Data Present Select in the Command register), or before issuing a Resume command. The Host Driver shall save the value of this register when the data transfer is suspended (as a result of a Suspend command) and restore it before issuing a Resume command. To prevent data loss, the Host Controller shall implement write protection for this register during data transactions. Writes to this register shall be ignored when the Command Inhibit (DAT) in the Present State register is 1.



### Access Method

**Type:** Memory Mapped I/O Register (Size: 16 bits)

**Offset:** [BAR] + Ch

**BAR Type:** PCI Configuration Register (Size: 32 bits)
**BAR Reference:** [B:0, D:17, F:0] + 10h

| 7 | 0b RW | **SPI_MODE (spi_mode):** SPI mode enable bit. 1 - SPI mode 0 - SD mode |
| 6 | 0b RW | **CMD_COMP_ATA (cmd_comp_ata):** Command Completion Signal Enable for CE-ATA Device. ???1??? - Device will send command completion Signal ???0??? - Device will not send command completion Signal |
| 5 | 0b RW | **BLK_SEL (blk_sel):** Multi / Single Block Select This bit is set when issuing multiple-block transfer commands using DAT line. For any other commands, this bit shall be set to 0. If this bit is 0, it is not necessary to set the Block Count register. (Refer to Table 2-8) 1 Multiple Block 0 Single Block |
| 4 | 0b RW | **Data Transfer Direction Select (data_tr_dir):** This bit defines the direction of DAT line data transfers. The bit is set to 1 by the Host Driver to transfer data from the SD card to the SD Host Controller, and it is set to 0 for all other commands.<br>• 1 = Read (Card to Host)<br>• 0 = Write (Host to Card) |

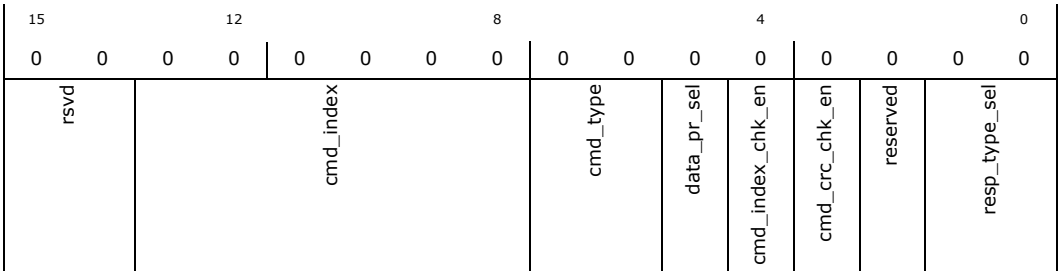
| 1 | 0b RW | **Block Count Enable (blk_count_en):** This bit is used to enable the Block Count register, which is only relevant for multiple block transfers. When this bit is 0, the Block Count register is disabled, which is useful in executing an infinite transfer. (Refer to Table 2-8). If ADMA2 data transfer is more than 65535 blocks, this bit shall be set to 0. In this case, data transfer length is designated by Descriptor Table.<br>• 1 = Enable<br>• 0 = Disable |
| 0 | 0b RW | **DMA Enable (dma_en):** This bit enables DMA functionality as described in section 1.4. DMA can be enabled only if it is supported as indicated in the Capabilities register. One of the DMA modes can be selected by DMA Select in the Host Control register. If DMA is not supported, this bit is meaningless and shall always read 0. If this bit is set to 1, a DMA operation shall begin when the Host Driver writes to the upper byte of Command register (00Fh).<br>• 1 = DMA Data transfer<br>• 0 = No data transfer or Non DMA data transfer |

## 16.6.6 Command Register (CMD)—Offset Eh

The Host Driver shall check the Command Inhibit (DAT) bit and Command Inhibit (CMD) bit in the Present State register before writing to this register. Writing to the upper byte of this register triggers SD command generation. The Host Driver has the responsibility to write this register because the Host Controller does not protect for writing when Command Inhibit (CMD) is set.



### Access Method

| 7:6 | 00b<br>RW | **Command Type (cmd_type):** There are three types of special commands: Suspend, Resume and Abort. These bits shall be set to 00b for all other commands. **(1) Suspend Command** If the Suspend command succeeds, the Host Controller shall assume the SD Bus has been released and that it is possible to issue the next command, which uses the DAT line. The Host Controller shall de-assert Read Wait for read transactions and stop checking busy for write transactions. The interrupt cycle shall start, in 4-bit mode. If the Suspend command fails, the Host Controller shall maintain its current state, and the Host Driver shall restart the transfer by setting Continue Request in the Block Gap Control register. (Refer to 3.12.1 Suspend Sequence). **(2) Resume Command** The Host Driver re-starts the data transfer by restoring the registers in the range of 000-00Dh. (Refer to Figure 1-4 in section 1.6 for the register map.) The Host Controller shall check for busy before starting write transfers. **(3) Abort Command** If this command is set when executing a read transfer, the Host Controller shall stop reads to the buffer. If this command is set when executing a write transfer, the Host Controller shall stop driving the DAT line. After issuing the Abort command, the Host Driver should issue a software reset. (Refer to 3.8 Abort Transaction).<br>• 11b = Abort -- CMD12, CMD52 for writing 'I/O Abort' in CCCR<br>• 10b = Resume -- CMD52 for writing 'Function Select' in CCCR<br>• 01b = Suspend -- CMD52 for writing 'Bus Suspend' in CCCR<br>• 00b = Normal -- Other commands |
| 5 | 0b<br>RW | **Data Present Select (data_pr_sel):** This bit is set to 1 to indicate that data is present and shall be transferred using the DAT line. It is set to 0 for the following: (1) Commands using only CMD line (ex. CMD52). (2) Commands with no data transfer but using busy signal on DAT[0] line (R1b or R5b ex. CMD38). (3) Resume command.<br>• 1 = Data Present<br>• 0 = No Data Present |

| 18 | 1b<br>RO | **Card Detect Pin Level (crd_det_pin_lvl):** This bit reflects the inverse value of the SDCD# pin. Debouncing is not performed on this bit. This bit may be valid when Card State Stable is set to 1, but it is not guaranteed because of propagation delay. Use of this bit is limited to testing since it must be debounced by software.<br>• 1 = Card present (SDCD#=0)<br>• 0 = No card present (SDCD#=1) |
| 17 | 1b<br>RO | **Card State Stable (crd_st_stable):** This bit is used for testing. If it is 0, the Card Detect Pin Level is not stable. If this bit is set to 1, it means the Card Detect Pin Level is stable. No Card state can be detected by this bit being set to 1 while Card Inserted is set to 0. The Software Reset For All in the Software Reset register shall not affect this bit.<br>• 1 = No Card or Inserted<br>• 0 = Reset or Debouncing |

| Bit Range | Default & Access | Field Name (ID): Description |
|---|---|---|
| 16 | 1b<br>RO | **Card Inserted (crd_ins):** This bit indicates whether a card has been inserted. The Host Controller shall debounce this signal so that the Host Driver will not need to wait for it to stabilize. Changing from 0 to 1 generates a Card Insertion interrupt in the Normal Interrupt Status register and changing from 1 to 0 generates a Card Removal interrupt in the Normal Interrupt Status register. The Software Reset For All in the Software Reset register shall not affect this bit. If a card is removed while its power is on and its clock is oscillating, the Host Controller shall clear SD Bus Power in the Power Control register (Refer to Section 2.2.11) and SD Clock Enable in the Clock Control register (Refer to Section 2.2.14). When this bit is changed from 1 to 0, the Host Controller shall immediately stop driving CMD and DAT[3:0] (tri-state). In addition, the Host Driver should clear the Host Controller by the Software Reset For All in Software Reset register. The card detect is active regardless of the SD Bus Power.<br>• 1 = Card Inserted<br>• 0 = Reset or Debouncing or No Card |

This read only flag indicates that valid data exists in the host side buffer. If this bit is 1, readable data exists in the buffer. A change of this bit from 1 to 0 occurs when all the block data is read from the buffer. A change of this bit from 0 to 1 occurs when block data is ready in the buffer and generates the Buffer Read Ready interrupt.<br>• 1 = Read enable<br>• 0 = Read disable |
| 10 | 0b<br>RO | **Buffer Write Enable (buf_wr_en):** This status is used for non-DMA write transfers. The Host Controller can implement multiple buffers to transfer data efficiently. This read only flag indicates if space is available for write data. If this bit is 1, data can be written to the buffer. A change of this bit from 1 to 0 occurs when all the block data is written to the buffer. A change of this bit from 0 to 1 occurs when top of block data can be written to the buffer and generates the Buffer Write Ready interrupt. The Host Controller should neither set Buffer Write Enable nor generate Buffer Write Ready Interrupt after the last block data is written to the Buffer Data Port Register.<br>• 1 = Write enable<br>• 0 = Write disable |
| 9 | 0b<br>RO | **Read Transfer Active (rd_tx_active):** This status is used for detecting completion of a read transfer. Refer to Section 3.12.3 for sequence details. This bit is set to 1 for either of the following conditions:<br>• After the end bit of the read command.<br>• When read operation is restarted by writing a 1 to Continue Request in the Block Gap Control register.<br>This bit is cleared to 0 for either of the following conditions:<br>• When the last data block as specified by block length is transferred to the System.<br>• In case of ADMA2, end of read operation is designated by Descriptor Table.<br>• When all valid data blocks in the Host Controller have been transferred to the System and no current block transfers are being sent as a result of the Stop At Block Gap Request being set to 1.<br>A Transfer Complete interrupt is generated when this bit changes to 0.<br>• 1 = Transferring data<br>• 0 = No valid data |

This bit is set in either of the following cases:<br>• After the end bit of the write command.<br>• When write operation is restarted by writing a 1 to Continue Request in the Block Gap Control register.<br>This bit is cleared in either of the following cases:<br>• After getting the CRC status of the last data block as specified by the transfer count (Single and Multiple) In case of ADMA2, transfer count is designated by Descriptor Table.<br>• After getting the CRC status of any block where data transmission is about to be stopped by a Stop At Block Gap Request.<br>During a write transaction, a Block Gap Event interrupt is generated when this bit is changed to 0, as the result of the Stop At Block Gap Request being set. (a) In the case of read transactions This status indicates whether a read transfer is executing on the SD Bus. Changing this value from 1 to 0 generates a Block Gap Event interrupt in the Normal Interrupt Status register, as the result of the Stop At Block Gap Request being set. Refer to Section 3.12.3 for details on timing. This bit shall be set in either of the following cases:<br>• After the end bit of the read command.<br>• When writing a 1 to Continue Request in the Block Gap Control register to restart a read transfer.<br>This bit shall be cleared in either of the following cases:<br>• When the end bit of the last data block is sent from the SD Bus to the Host Controller. In case of ADMA2, the last block is designated by the last transfer of Descriptor Table.<br>• When a read transfer is stopped at the block gap initiated by a Stop At Block Gap Request.<br>The Host Controller shall stop read operation at the start of the interrupt cycle of the next block gap by driving Read Wait or stopping SD clock. If the Read Wait signal is already driven (due to data buffer cannot receive data), the Host Controller can continue to stop read operation by driving the Read Wait signal. It is necessary to support Read Wait in order to use suspend / resume function. (b) In the case of write transactions This status indicates that a write transfer is executing on the SD Bus. Changing this value from 1 to 0 generate a Transfer Complete interrupt in the Normal Interrupt Status register. Refer to Section 3.12.4 for sequence details. This bit shall be set in either of the following cases:<br>• After the end bit of the write command.<br>• When writing to 1 to Continue Request in the Block Gap Control register to continue a write transfer.<br>This bit shall be cleared in either of the following cases:<br>• When the SD card releases write busy of the last data block. If SD card does not drive busy signal for 8 SD Clocks, the Host Controller shall consider the card drive 'Not Busy'. In case of ADMA2, the last block is designated by the last transfer of Descriptor Table.<br>• When the SD card releases write busy prior to waiting for write transfer as a result of a Stop At Block Gap Request.<br>(c) Command with busy This status indicates whether a command indicates busy (ex. erase command for memory) is executing on the SD Bus. This bit is set after the end bit of the command with busy and cleared when busy is de-asserted. Changing this bit from 1 to 0 generate a Transfer Complete interrupt in the Normal Interrupt Status register. Refer Figure 2-11 to Figure 2-13.<br>• 1 = DAT Line Active<br>• 0 = DAT Line Inactive |

| 1 | 0b<br>RO | **Command Inhibit (DAT) (cmd_inhibit_dat):** This status bit is generated if either the DAT Line Active or the Read Transfer Active is set to 1. If this bit is 0, it indicates the Host Controller can issue the next SD Command. Commands with busy signal belong to Command Inhibit (DAT) (ex. R1b, R5b type). Changing from 1 to 0 generates a Transfer Complete interrupt in the Normal Interrupt Status register. **Note:** The SD Host Driver can save registers in the range of 000-00Dh for a suspend transaction after this bit has changed from 1 to 0.<br>• 1 Cannot issue command which uses the DAT line<br>• 0 Can issue command which uses the DAT line |
| 0 | 0b<br>RO | **Command Inhibit (CMD) (cmd_inhibit_cmd):** Command Inhibit (CMD) If this bit is 0, it indicates the CMD line is not in use and the Host Controller can issue a SD Command using the CMD line. cleared when the command response is received. Auto CMD12 and Auto CMD23 consist of two responses. In this case, this bit is not cleared by the response of CMD12 or CMD23 but cleared by the response of a read/write command. Status issuing Auto CMD12 is not read from this bit. So if a command is issued during Auto CMD12 operation, Host Controller shall manage to issue two commands: CMD12 and a command set by Command register. Even if the Command Inhibit (DAT) is set to 1, commands using only the CMD line can be issued if this bit is 0. Changing from 1 to 0 generates a Command Complete Interrupt in the Normal Interrupt Status register. If the Host Controller cannot issue the command because of a command conflict error (Refer to Command CRC Error in Section 2.2.18) or because of Command Not Issued By Auto CMD12 Error (Refer to Section 2.2.23), this bit shall remain 1 and the Command Complete is not set.<br>• 1 Cannot issue command<br>• 0 Can issue command using only CMD line |

Setting to 1 enables interrupt detection at the block gap for a multiple block transfer. Setting to 0 disables interrupt detection during a multiple block transfer. If the SD card cannot signal an interrupt during a multiple block transfer, this bit should be set to 0. When the Host Driver detects an SD card insertion, it shall set this bit according to the CCCR of the SDIO card.<br>• 1 = Enabled<br>• 0 = Disabled |
| 2 | 0b<br>RW | **Read Wait Control (rd_wait_ctl):** The read wait function is optional for SDIO cards. If the card supports read wait, set this bit to enable use of the read wait protocol to stop read data using the DAT[2] line. Otherwise, the Host Controller has to stop the SD Clock to hold read data, which restricts commands generation. When the Host Driver detects an SD card insertion, it shall set this bit according to the CCCR of the SDIO card. If the card does not support read wait, this bit shall never be set to 1, otherwise DAT line conflict may occur. If this bit is set to 0, Suspend/Resume cannot be supported.<br>• 1 = Enable Read Wait Control<br>• 0 = Disable Read Wait Control |

To cancel stop at the block gap, set Stop At Block Gap Request to 0 and set this bit 1 to restart the transfer. The Host Controller automatically clears this bit in either of the following cases:<br>• In the case of a read transaction, the DAT Line Active changes from 0 to 1 as a read transaction restarts.<br>• In the case of a write transaction, the Write Transfer Active changes from 0 to 1 as the write transaction restarts.<br>Therefore, it is not necessary for Host Driver to set this bit to 0. | 0 | 0b<br>RW | **Stop at Block Gap Request (stp_blk_gap_req):** This bit is used to stop executing read and write transaction at the next block gap for non-DMA, SDMA and ADMA transfers. The Host Driver shall leave this bit set Copyright 2002-2011 SD Association SD Host Controller Simplified Specification Version 3.00 44 to 1 until the Transfer Complete is set to 1. Clearing both Stop At Block Gap Request and Continue Request shall not cause the transaction to restart. When Host Controller version is 1.00, the Host Driver can set this bit if the card supports Read Wait Control. When Host Controller version is 2.00 or later, the Host Driver can set this bit regardless of the card supports Read Wait Control. The Host Controller shall stop read transfer by using Read Wait or stopping SD clock. In case of write transfers in which the Host Driver writes data to the Buffer Data Port register, the Host Driver shall set this bit after all block data is written. If this bit is set to 1, the Host Driver shall not write data to Buffer Data Port register. This bit affects Read Transfer Active, Write Transfer Active, DAT Line Active and Command Inhibit (DAT) in the Present State register. Regarding detailed control of bits D01 and D00, refer to Section 3.8 and 3.12.<br>• 1 = Stop<br>• 0 = Transfer |

### 16.6.16 Wakeup Control Register (WAKEUP_CTL)—Offset 2Bh

This register is mandatory for the Host Controller, but wakeup functionality depends on the Host Controller system hardware and software. The Host Driver shall maintain voltage on the SD Bus, by setting SD Bus Power to 1 in the Power Control register, when wakeup event via Card Interrupt is desired. Wakeup Event is not supported by Host Controller. Sideband wake via GPIO pin and register shall be used instead. During RTD3, GPIO register is readable and GPIO signal is routed to APIC.

|---|---|---|
| 15:8 | 00h<br>RW | **SDCLK Frequency Select (sdclk_freq_sel):** This register is used to select the frequency of the SDCLK pin. The definition of this field is dependent on the Host Controller Version. **(1) 8-bit Divided Clock Mode** This mode is supported by the Host Controller Version 1.00 and 2.00. The frequency is not programmed directly, rather, this register holds the divisor of the Base Clock Frequency For SD Clock in the capabilities register. Only the following settings are allowed. **(1) 8-bit Divided Clock Mode**<br>• 80h = base clock divided by 256<br>• 40h = base clock divided by 128<br>• 20h = base clock divided by 64<br>• 10h = base clock divided by 32<br>• 08h = base clock divided by 16<br>• 04h = base clock divided by 8<br>• 02h = base clock divided by 4<br>• 01h = base clock divided by 2<br>• 00h = base clock(10MHz and up)<br>Setting 00h specifies the highest frequency of the SD Clock. When setting multiple bits, the most significant bit is used as the divisor, but it should not be set. The three default divider values can be calculated by the frequency that is defined by the Base Clock Frequency For SD Clock in the Capabilities register.<br>• 400KHz divider value<br>• 25MHz divider value<br>• 50MHz divider value<br>According to the Physical Layer Specification, the maximum SD Clock frequency is 25 MHz in normal speed mode and 50MHz in high speed mode, and shall never exceed this limit. The frequency of the SDCLK is set by the following formula: Clock Frequency = (Base Clock) / divisor Thus, choose the smallest possible divisor which results in a clock frequency that is less than or equal to the target frequency. For example, if the Base Clock Frequency For SD Clock in the Capabilities register has the value 33MHz, and the target frequency is 25MHz, then choosing the divisor value of 01h will yield 16.5MHz, which is the nearest frequency less than or equal to the target. Similarly, to approach a clock value of 400KHz, the divisor value of 40h yields the optimal clock value of 258KHz. **(2) 10-bit Divided Clock Mode** Host Controller Version 3.00 supports this mandatory mode instead of the 8-bit Divided Clock Mode. The length of divider is extended to 10 bits, and all divider values shall be supported.<br>• 3FFh = 1/2046 Divided Clock<br>• N = 1/2N Divided Clock (Duty 50%)<br>• 002h = 1/4 Divided Clock<br>• 001h = 1/2 Divided Clock<br>• 000h = Base Clock (10MHz and up)<br>• 3FFh = Base Clock * M / 1024<br>• ..... .....<br>• N - 1 = Base Clock * M / N<br>• ..... .....<br>• 002h = Base Clock * M / 3<br>• 001h = Base Clock * M / 2<br>• 000h = Base Clock * M<br>This field depends on setting of Preset Value Enable in the Host Control 2 register. ## 16.6.20 Normal Interrupt Status Register (NML_INT_STATUS)—Offset 30h

The Normal Interrupt Status Enable affects reads of this register, but Normal Interrupt Signal Enable does not affect these reads. An interrupt is generated when the Normal Interrupt Signal Enable is enabled and at least one of the status bits is set to 1. Writing 1 to a bit of RW1C attribute clears it; writing 0 keeps the bit unchanged. Writing 1 to a bit of ROC attribute keeps the bit unchanged. More than one status can be cleared with a single register write. The Card Interrupt is cleared when the card stops asserting the interrupt; that is, when the Card Driver services the interrupt condition.

In 1-bit mode, the Host Controller shall detect the Card Interrupt without SD Clock to support wakeup. In 4-bit mode, the card interrupt signal is sampled during the interrupt cycle, so there are some sample delays between the interrupt signal from the SD card and the interrupt to the Host System. When this status has been set and the Host Driver needs to start this interrupt service, Card Interrupt Status Enable in the Normal Interrupt Status Enable register may be set to 0 in order to clear the card interrupt statuses latched in the Host Controller and to stop driving the interrupt signal to the Host System. After completion of the card interrupt service (It should reset interrupt factors in the SD card and the interrupt signal may not be asserted), set Card Interrupt Status Enable to 1 and start sampling the interrupt signal again. Interrupt detected by DAT[1] is supported when there is a card per slot. In case of shared bus, interrupt pins are used to detect interrupts. This interrupt is generated in two cases. The first is when a data transfer is completed as specified by data length (After the last data has been read to the Host System). The second is when data has stopped at the block gap and completed the data transfer by setting the Stop At Block Gap Request in the Block Gap Control register (After valid data has been read to the Host System). Refer to Section 3.12.3 for more details on the sequence of events. **(2) In the case of a Write Transaction** This bit is set at the falling edge of the DAT Line Active Status. This interrupt is generated in two cases. The first is when the last data is written to the SD card as specified by data length and the busy signal released. The second is when data transfers are stopped at the block gap by setting Stop At Block Gap Request in the Block Gap Control register and data transfers completed. Command Complete is not generated by the response of CMD12 or CMD23 but generated by the response of a read/write command. Refer to Command Inhibit (CMD) in the Present State register for how to control this bit. Command Timeout Error has higher priority than Command Complete. If both bits are set to 1, it can be considered that the response was not received correctly. ## 16.6.21 Error Interrupt Status Register (ERR_INT_STATUS)—Offset 32h

Signals defined in this register can be enabled by the Error Interrupt Status Enable register, but not by the Error Interrupt Signal Enable register. The interrupt is generated when the Error Interrupt Signal Enable is enabled and at least one of the statuses is set to 1. Writing to 1 clears the bit, and writing to 0 keeps the bit unchanged. More than one status can be cleared at the one register write.

The state of the ADMA at an error occurrence is saved in the ADMA Error Status Register. In addition, the Host Controller generates this Interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state. **ADMA Error State** in the ADMA Error Status indicates that an error occurs in ST_FDS state.The Host Driver may find that Valid bit is not set at the error descriptor.<br>• 0 = error<br>• 1 = no error |

This bit is set when detecting that one of the bits D00-D04 in Auto CMD Error Status register has changed from 0 to 1. In case of Auto CMD12, this bit is set to 1, not only when the errors in Auto CMD12 occur but also when Auto CMD12 is not executed due to the previous command error.<br>• 1 = error<br>• 0 = no error |

If the Host Controller supports the Current Limit function, it can be protected from an illegal card by stopping power supply to the card in which case this bit indicates a failure status. Reading 1 means the Host Controller is not supplying power to SD card due to some failure. Reading 0 means that the Host Controller is supplying power and no error has occurred. The Host Controller may require some sampling time to detect the current limit. If a response is returned and the **Command Timeout Error** is set to 0(indicating no timeout), this bit is set to 1 when detecting a CRC error in the command response. The Host Controller detects a CMD line conflict by monitoring the CMD line when a command is issued. If the Host Controller drives the CMD line to 1 level, but detects 0 level on the CMD line at the next SD clock edge, then the Host Controller shall abort the command (Stop driving CMD line) and set this bit to 1. The Command Timeout Error shall also be set to 1 to distinguish CMD line conflict (refer to tabular data in the spec. that explains the relationship between **Command CRC Error** and **Command Timeout Error**).<br>• 1 = CRC Error Generated.<br>• 0 = no error |

## 16.6.22 Normal Interrupt Status Enable (NRM_INT_STATUS_EN)—Offset 34h

Setting to 1 enables Interrupt Status. **Implementation Note:** The Host Controller may sample the card interrupt signal during interrupt period, and may hold its value in the flip-flop. If the **Card Interrupt Status Enable** is set to 0, the Host Controller shall clear all internal signals regarding Card Interrupt.

If this bit is set to 1, the Host Driver can stop the SDCLK during asynchronous interrupt period to save power. During this period, the Host Controller continues to deliver Card Interrupt to the host when it is asserted by the Card. ## 16.6.31 Force Event Register for Error Interrupt Status (FORCE_EVENT_ERR_INT_STAT)—Offset 52h

Error Interrupt Status register can be written. The effect of a write to this address will be reflected in the Error Interrupt Status Register if the corresponding bit of the Error Interrupt Status Enable Register is set.

- Writing 1 : set each bit of the Error Interrupt Status Register
- Writing 0 : no effect

**Note:** By setting this register, the Error Interrupt can be set in the Error Interrupt Status register. In order to generate interrupt signal, both the Error Interrupt Status Enable and Error Interrupt Signal Enable shall be set.

### 16.6.32 ADMA Error Status Register (ADMA_ERR_STAT)—Offset 54h

When ADMA Error Interrupt occurs, the ADMA Error States field in this register holds the ADMA state and the ADMA System Address Register holds the address around the error descriptor. To recover from the error, the Host Driver requires the ADMA state to identify the error descriptor address as follows:

- ST_STOP: Previous location set in the ADMA System Address register is the error descriptor address
- ST_FDS: Current location set in the ADMA System Address register is the error descriptor address
- ST_CADR: This sate is never set because do not generate ADMA error in this state.

- ST_TFR: Previous location set in the ADMA System Address register is the error descriptor address

The Host Controller generates the ADMA Error Interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state. In this case, ADMA Error State indicates that an error occurs at ST_FDS state. The Host Driver may find that the Valid bit is not set in the error descriptor.

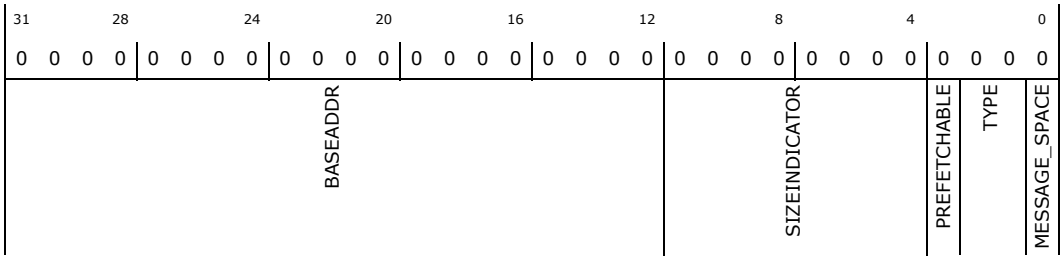
## 16.7.5 Base Address Register (BAR)—Offset 10h



Each AHB device is a single function device with only a single BAR associated with it. Bits 31:4 indicate the Base Address register. Power-up software can determine how much address space the AHB Device requires by writing a value of all 1's to the register and then reading the value back. Bridge will return 0's in all don't-care address bits, effectively specifying the address space required. Unimplemented Base Address registers are hardwired to zero. This is the Size Indicator Read only bits of the register.

| Bit Range | Default & Access | Field Name (ID): Description |
|---|---|---|
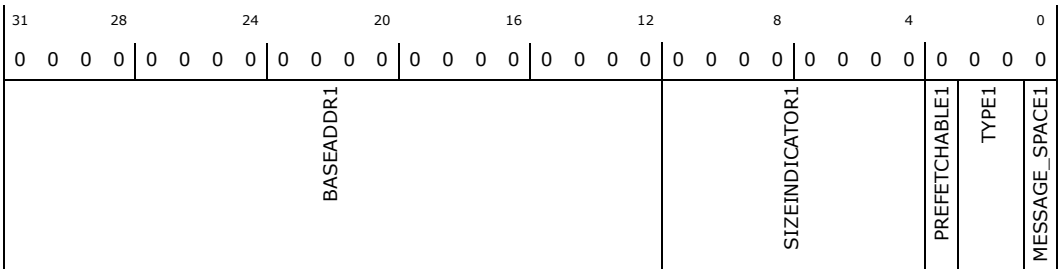
| 11:4 | 00h<br>RO | **Size Indicator (Read Only) (SIZEINDICATOR):** Always returns zero. The size of this register depends on the size of the Memory space. This size is determined by a top level of STRAP values as 0s. |
| 3 | 0h<br>RO | **Prefetchable (PREFETCHABLE):** Indicates that this bar is not prefetchable. |
| 2:1 | 0h<br>RO | **Type (TYPE):** '00' indicates that the BAR lies in 32 bit address range. |
| 0 | 0h<br>RO | **Memory Space Indicator (MESSAGE_SPACE):** 0 Indicates that this BAR is present in the memory space. |

## 16.7.6 Base Address Register 1 (BAR1)—Offset 14h



Memory accesses to BAR1 region access the PCI configuration space for the LPIO device. BAR1 region is always 4K. However SW accesses through BAR1 should only access the regular PCI configuration space. BAR1 memory accesses which do not access a defined PCI configuration register are treated as accesses to a reserved register.

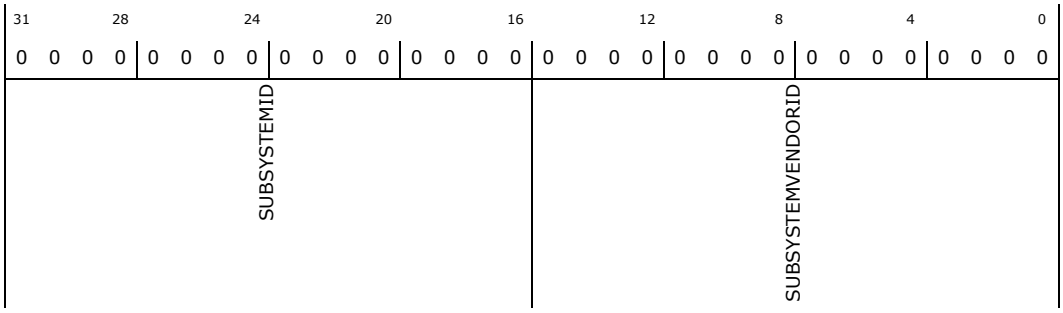
### Access Method

**Type:** PCI Configuration Register (Size: 32 bits)

**Offset:** [B:0, D:18, F:0] + 14h

**Default:** 00000000h

| Bit Range | Default & Access | Field Name (ID): Description |
|---|---|---|
| 31:12 | 00000h<br>RW | **Base Address Register1 (BASEADDR1):** This field is present if BAR1 is enabled through private config space. If this register is disabled then this is RO and always returns 0. |
| 11:4 | 00h<br>RO | **Size Indicator1 (SIZEINDICATOR1):** Always will be zero as minimum size is 4K. |
| 3 | 0h<br>RO | **Prefetchable (PREFETCHABLE1):** Indicates that this bar is not prefetchable. |
| 2:1 | 0h<br>RO | **Type (TYPE1):** '00' indicates that the BAR lies in 32 bit address range. |
| 0 | 0h<br>RO | **Memory Space Indicator (MESSAGE_SPACE1):** 0 Indicates that this BAR is present in the memory space. |



## 16.7.7 Subsystem Vendor ID and Subsystem ID Register (SUBSYSTEMID)—Offset 2Ch

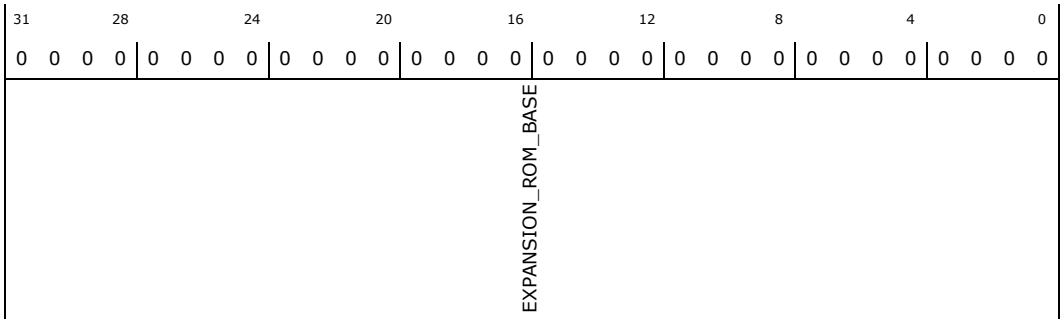
### Access Method

**Type:** PCI Configuration Register (Size: 32 bits)

**Offset:** [B:0, D:18, F:0] + 2Ch

**Default:** 00000000h

| Bit Range | Default & Access | Field Name (ID): Description |
|---|---|---|
| 31:16 | 0000h RW/O | **Subsystem ID (SUBSYSTEMID):** This register should be implemented for any function that could be instantiated more than once in a given system. Th is register makes it possible for the operating environment to distinguish one audio subsystem from the other. This is a Read Write Once register. |
| 15:0 | 0000h RW/O | **Subsystem Vendor ID (SUBSYSTEMVENDORID):** This register should be implemented for any function that could be instantiated more than once in a given system. This register enables the operating environment to distinguish one subsystem from the other. This is a Read Write Once register. |



## 16.7.8 Expansion ROM Base Address Register (EXPANSION_ROM_BASEADDR)—Offset 30h

### Access Method

**Type:** PCI Configuration Register (Size: 32 bits)

**Offset:** [B:0, D:18, F:0] + 30h

**Default:** 00000000h

| Bit Range | Default & Access | Field Name (ID): Description |
|---|---|---|

## 16.7.9 Capabilities Pointer Register (CAPABILITYPTR)—Offset 34h

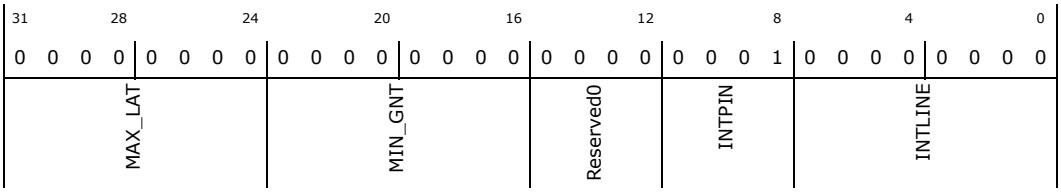
### Access Method

**Type:** PCI Configuration Register (Size: 32 bits)

**Offset:** [B:0, D:18, F:0] + 34h

**Default:** 00000080h

| Bit Range | Default & Access | Field Name (ID): Description |
|---|---|---|
| 31:8 | 000000h RO | **Reserved0:** Reserved. |
| 7:0 | 80h RO | **Capabilities Pointer (CAPPTR_POWER):** Indicates what the next capability is. This capability can be programmed to be PM Capability (0x80) if PM Capability is enabled in SB. When PM capability is disabled, this register is 00h. |



## 16.7.10 Interrupt Register (INTERRUPTREG)—Offset 3Ch

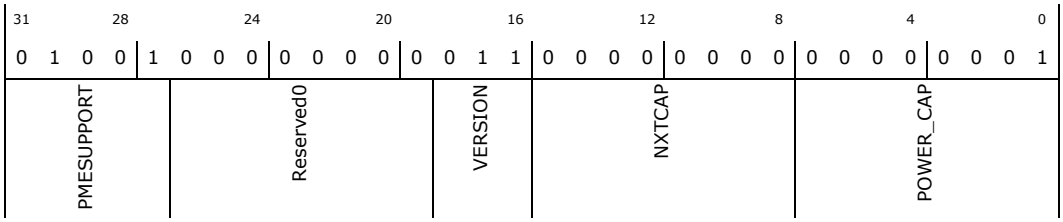
### Access Method

**Type:** PCI Configuration Register (Size: 32 bits)

**Offset:** [B:0, D:18, F:0] + 3Ch

**Default:** 00000100h

| Bit Range | Default & Access | Field Name (ID): Description |
|---|---|---|
| 31:24 | 00h RO | **Max_Lat (MAX_LAT):** Value of 0 indicates that the device has no major requirements for the settings of latency timers. |
| 23:16 | 00h RO | **Min_Gnt (MIN_GNT):** Value of 0 indicates that the device has no major requirements for the settings of latency timers. |
| 15:12 | 0h RO | **Reserved0:** Reserved. |
| 11:8 | 1h RO | **Interrupt Pin (INTPIN):** Each AHB IP on Bridge is a single function device. Hence Bridge only generates INTA on IOSF SB. The Fabric on AHB Bridge appears as a Multifunction device. Interrupt Pin Value in this register is reflected from the IPIN value in the private configuration space. |
| 7:0 | 00h RW | **Interrupt Line (INTLINE):** Bridge does not use this field directly. It is used to communicate to software the interrupt line that the interrupt pin is connected to. |



## 16.7.11 Power Management Capability ID Register (POWERCAPID)—Offset 80h

### Access Method

**Type:** PCI Configuration Register (Size: 32 bits)

**Offset:** [B:0, D:18, F:0] + 80h

**Default:** 48030001h

| Bit Range | Default & Access | Field Name (ID): Description |

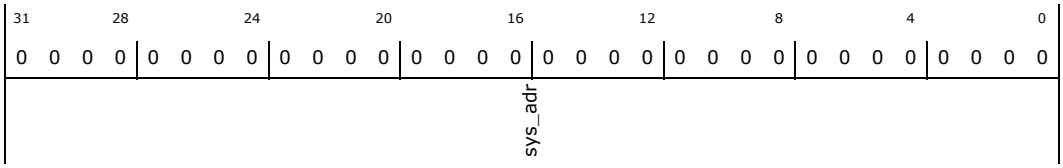
## 16.8.1 SDMA System Address / Argument 2 Register (SYS_ADR)—Offset 0h

This register contains the physical system memory address used for DMA transfers or the second argument for the Auto CMD23.



### Access Method

**Type:** Memory Mapped I/O Register (Size: 32 bits)

**Offset:** [BAR] + 0h

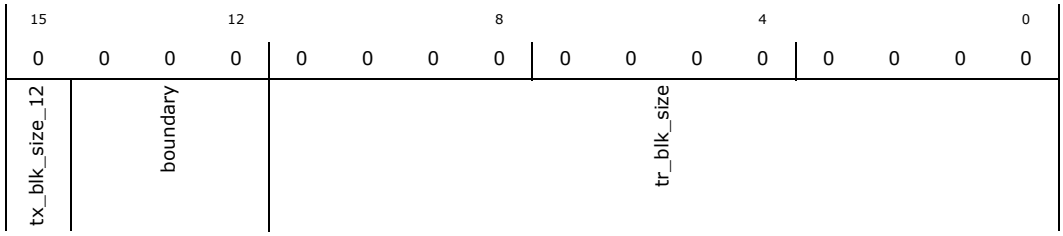
**BAR Type:** PCI Configuration Register (Size: 32 bits)
**BAR Reference:** [B:0, D:18, F:0] + 10h

**Default:** 00000000h

| Bit Range | Default & Access | Field Name (ID): Description |
|---|---|---|
| 31:0 | 00000000h<br>RW | **SDMA System Address (sys_adr): (1) SDMA System Address**<br>This register contains the system memory address for a SDMA transfer. When the Host Controller stops a SDMA transfer, this register shall point to the system address of the next contiguous data position. It can be accessed only if no transaction is executing (i.e., after a transaction has stopped). Read operations during transfers may return an invalid value.<br>The Host Driver shall initialize this register before starting a SDMA transaction. After SDMA has stopped, the next system address of the next contiguous data position can be read from this register.<br>The SDMA transfer waits at each boundary specified by the Host SDMA Buffer Boundary in the Block Size register. The Host Controller generates a DMA Interrupt to request the Host Driver to update this register. The Host Driver sets the next system address of the next data position to this register.<br>When the uppermost byte of this register (003h) is written, the Host Controller restarts the SDMA transfer.<br>When restarting SDMA by the Resume command or by setting Continue Request in the Block Gap Control register, the Host Controller shall start at the next contiguous address stored here in the SDMA System Address register. ADMA does not use this register. **(2) Argument 2**<br>This register is used with the Auto CMD23 to set a 32-bit block count value to the argument of the CMD23 while executing Auto CMD23.<br>If Auto CMD23 is used with ADMA, the full 32-bit block count value can be used. If Auto CMD23 is used without AMDA, the available block count value is limited by the Block Count register. 65535 blocks is the maximum value in this case. |

## 16.8.2 Block Size Register (BLK_SIZE)—Offset 4h

This register is used to configure the number of bytes in a data block.



### Access Method

**Type:** Memory Mapped I/O Register (Size: 16 bits)

**Offset:** [BAR] + 4h

**BAR Type:** PCI Configuration Register (Size: 32 bits)
**BAR Reference:** [B:0, D:18, F:0] + 10h

|---|---|---|
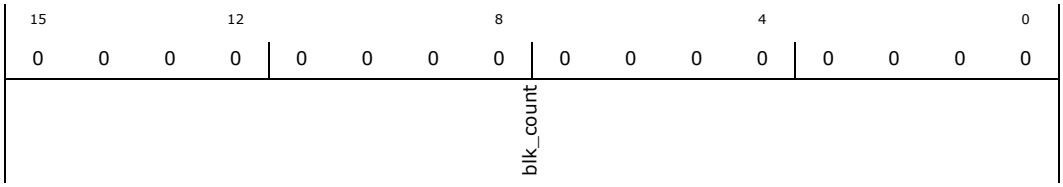
| 14:12 | 000b<br>RW | **Host SDMA Buffer Boundary (boundary):** The large contiguous memory space may not be available in the virtual memory system. To perform long SDMA transfer, SDMA System Address register shall be updated at every system memory boundary during SDMA transfer. These bits specify the size of contiguous buffer in the system memory. The SDMA transfer shall wait at each boundary specified by these fields and the Host Controller generates the DMA Interrupt to request the Host Driver to update the SDMA System Address register. At the end of transfer, the Host Controller may issue or may not issue DMA Interrupt. In particular, DMA Interrupt shall not be issued after Transfer Complete Interrupt is issued. In case of this register is set to 0 (buffer size = 4K bytes), lower 12-bit of byte address points data in the contiguous buffer and the upper 20-bit points the location of the buffer in the system memory. The SDMA transfer stops when the Host Controller detects carry out of the address from bit 11 to 12. These bits shall be supported when the SDMA Support in the Capabilities register is set to 1 and this function is active when the DMA Enable in the Transfer Mode register is set to 1. ADMA does not use this register.<br>• 000b = 4K bytes (Detects A11 carry out)<br>• 001b = 8K bytes (Detects A12 carry out)<br>• 010b = 16K Bytes (Detects A13 carry out)<br>• 011b = 32K Bytes (Detects A14 carry out)<br>• 100b = 64K bytes (Detects A15 carry out)<br>• 101b = 128K Bytes (Detects A16 carry out)<br>• 110b = 256K Bytes (Detects A17 carry out)<br>• 111b = 512K Bytes (Detects A18 carry out) |

Values ranging from 1 up to the maximum buffer size can be set. In case of memory, it shall be set up to 512 bytes (Refer to Implementation Note in Section 1.7.2 *Determining Buffer Block Length*). It can be accessed only if no transaction is executing (i.e., after a transaction has stopped). Read operations during transfers may return an invalid value, and write operations shall be ignored.<br>• 0800h = 2048 Bytes<br>• . . .<br>• 0200h = 512 Bytes<br>• 01FFh = 511 Bytes<br>• . . .<br>• 0004h = 4 Bytes<br>• 0003h = 3 Bytes<br>• 0002h = 2 Bytes<br>• 0001h = 1 Byte<br>• 0000h = No data transfer |

## 16.8.3 Block Count Register (BLK_COUNT)—Offset 6h

This register is used to configure the number of data blocks.



### Access Method

**Type:** Memory Mapped I/O Register (Size: 16 bits)

**Offset:** [BAR] + 6h

**BAR Type:** PCI Configuration Register (Size: 32 bits)
**BAR Reference:** [B:0, D:18, F:0] + 10h

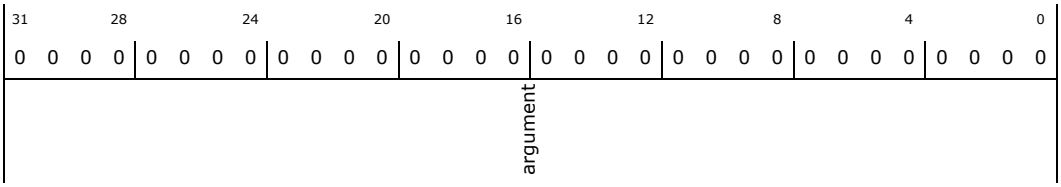
| 15:0 | 0000h<br>RW | **Blocks Count For Current Transfer (blk_count):** This register is enabled when Block Count Enable in the Transfer Mode register is set to 1, and is valid only for multiple block transfers. The Host Driver shall set this register to a value between 1 and the maximum block count. The HC decrements the block count after each block transfer, and stops when the count reaches zero. Setting the block count to 0 results in no data blocks being transferred. This register should be accessed only when no transaction is executing (i.e., after transactions are stopped). During data transfer, read operations on this register may return an invalid value and write operations are ignored. When saving transfer context as a result of a Suspend command, the number of blocks yet to be transferred can be determined by reading this register. When restoring transfer context prior to issuing a Resume command, the HD shall restore the previously saved block count.<br>• 0000h = Stop Count<br>• 0001h = 1 block<br>• 0002h = 2 blocks<br>• . . .<br>• FFFFh = 65535 blocks |

## 16.8.4 Argument 1 Register (ARGUMENT)—Offset 8h

This register contains the SD Command Argument.



### Access Method

**Type:** Memory Mapped I/O Register (Size: 32 bits)

**Offset:** [BAR] + 8h

**BAR Type:** PCI Configuration Register (Size: 32 bits)
**BAR Reference:** [B:0, D:18, F:0] + 10h

## 16.8.5 Transfer Mode Register (TX_MODE)—Offset Ch

This register is used to control the operation of data transfers. The Host Driver shall set this register before issuing a command which transfers data (Refer to Data Present Select in the Command register), or before issuing a Resume command. The Host Driver shall save the value of this register when the data transfer is suspended (as a result of a Suspend command) and restore it before issuing a Resume command. To prevent data loss, the Host Controller shall implement write protection for this register during data transactions. Writes to this register shall be ignored when the Command Inhibit (DAT) in the Present State register is 1.

One of the DMA modes can be selected by DMA Select in the Host Control register. If DMA is not supported, this bit is meaningless and shall always read 0. If this bit is set to 1, a DMA operation shall begin when the Host Driver writes to the upper byte of Command register (00Fh).<br>• 1 = DMA Data transfer<br>• 0 = No data transfer or Non DMA data transfer |

## 16.8.6 Command Register (CMD)—Offset Eh

The Host Driver shall check the Command Inhibit (DAT) bit and Command Inhibit (CMD) bit in the Present State register before writing to this register. Writing to the upper byte of this register triggers SD command generation. The Host Driver has the responsibility to write this register because the Host Controller does not protect for writing when Command Inhibit (CMD) is set.

| 7:6 | 00b<br>RW | **Command Type (cmd_type):** There are three types of special commands: Suspend, Resume and Abort. These bits shall be set to 00b for all other commands. **(1) Suspend Command** If the Suspend command succeeds, the Host Controller shall assume the SD Bus has been released and that it is possible to issue the next command, which uses the DAT line. The Host Controller shall de-assert Read Wait for read transactions and stop checking busy for write transactions. The interrupt cycle shall start, in 4-bit mode. If the Suspend command fails, the Host Controller shall maintain its current state, and the Host Driver shall restart the transfer by setting Continue Request in the Block Gap Control register. (Refer to 3.12.1 Suspend Sequence). **(2) Resume Command** The Host Driver re-starts the data transfer by restoring the registers in the range of 000-00Dh. (Refer to Figure 1-4 in section 1.6 for the register map.) The Host Controller shall check for busy before starting write transfers. **(3) Abort Command** If this command is set when executing a read transfer, the Host Controller shall stop reads to the buffer. If this command is set when executing a write transfer, the Host Controller shall stop driving the DAT line. After issuing the Abort command, the Host Driver should issue a software reset. (Refer to 3.8 Abort Transaction).<br>• 11b = Abort -- CMD12, CMD52 for writing 'I/O Abort' in CCCR<br>• 10b = Resume -- CMD52 for writing 'Function Select' in CCCR<br>• 01b = Suspend -- CMD52 for writing 'Bus Suspend' in CCCR<br>• 00b = Normal -- Other commands |

| 18 | 1b<br>RO | **Card Detect Pin Level (crd_det_pin_lvl):** This bit reflects the inverse value of the SDCD# pin. Debouncing is not performed on this bit. This bit may be valid when Card State Stable is set to 1, but it is not guaranteed because of propagation delay. Use of this bit is limited to testing since it must be debounced by software.<br>• 1 = Card present (SDCD#=0)<br>• 0 = No card present (SDCD#=1) |
| 17 | 1b<br>RO | **Card State Stable (crd_st_stable):** This bit is used for testing. If it is 0, the Card Detect Pin Level is not stable. If this bit is set to 1, it means the Card Detect Pin Level is stable. No Card state can be detected by this bit being set to 1 while Card Inserted is set to 0. The Software Reset For All in the Software Reset register shall not affect this bit.<br>• 1 = No Card or Inserted<br>• 0 = Reset or Debouncing |

| Bit Range | Default & Access | Field Name (ID): Description |
|---|---|---|
| 16 | 1b<br>RO | **Card Inserted (crd_ins):** This bit indicates whether a card has been inserted. The Host Controller shall debounce this signal so that the Host Driver will not need to wait for it to stabilize. Changing from 0 to 1 generates a Card Insertion interrupt in the Normal Interrupt Status register and changing from 1 to 0 generates a Card Removal interrupt in the Normal Interrupt Status register. The Software Reset For All in the Software Reset register shall not affect this bit. If a card is removed while its power is on and its clock is oscillating, the Host Controller shall clear SD Bus Power in the Power Control register (Refer to Section 2.2.11) and SD Clock Enable in the Clock Control register (Refer to Section 2.2.14). When this bit is changed from 1 to 0, the Host Controller shall immediately stop driving CMD and DAT[3:0] (tri-state). In addition, the Host Driver should clear the Host Controller by the Software Reset For All in Software Reset register. This read only flag indicates that valid data exists in the host side buffer. If this bit is 1, readable data exists in the buffer. A change of this bit from 1 to 0 occurs when all the block data is read from the buffer. A change of this bit from 0 to 1 occurs when block data is ready in the buffer and generates the Buffer Read Ready interrupt.<br>• 1 = Read enable<br>• 0 = Read disable |
| 10 | 0b<br>RO | **Buffer Write Enable (buf_wr_en):** This status is used for non-DMA write transfers. The Host Controller can implement multiple buffers to transfer data efficiently. This read only flag indicates if space is available for write data. If this bit is 1, data can be written to the buffer. A change of this bit from 1 to 0 occurs when all the block data is written to the buffer. A change of this bit from 0 to 1 occurs when top of block data can be written to the buffer and generates the Buffer Write Ready interrupt. The Host Controller should neither set Buffer Write Enable nor generate Buffer Write Ready Interrupt after the last block data is written to the Buffer Data Port Register.<br>• 1 = Write enable<br>• 0 = Write disable |
| 9 | 0b<br>RO | **Read Transfer Active (rd_tx_active):** This status is used for detecting completion of a read transfer. Refer to Section 3.12.3 for sequence details. This bit is set to 1 for either of the following conditions:<br>• After the end bit of the read command.<br>• When read operation is restarted by writing a 1 to Continue Request in the Block Gap Control register.<br>This bit is cleared to 0 for either of the following conditions:<br>• When the last data block as specified by block length is transferred to the System.<br>• In case of ADMA2, end of read operation is designated by Descriptor Table.<br>• When all valid data blocks in the Host Controller have been transferred to the System and no current block transfers are being sent as a result of the Stop At Block Gap Request being set to 1.<br>A Transfer Complete interrupt is generated when this bit changes to 0.<br>• 1 = Transferring data<br>• 0 = No valid data |

(a) In the case of read transactions This status indicates whether a read transfer is executing on the SD Bus. Changing this value from 1 to 0 generates a Block Gap Event interrupt in the Normal Interrupt Status register, as the result of the Stop At Block Gap Request being set. Refer to Section 3.12.3 for details on timing. This bit shall be set in either of the following cases:<br>• After the end bit of the read command.<br>• When writing a 1 to Continue Request in the Block Gap Control register to restart a read transfer.<br>This bit shall be cleared in either of the following cases:<br>• When the end bit of the last data block is sent from the SD Bus to the Host Controller. In case of ADMA2, the last block is designated by the last transfer of Descriptor Table.<br>• When a read transfer is stopped at the block gap initiated by a Stop At Block Gap Request.<br>The Host Controller shall stop read operation at the start of the interrupt cycle of the next block gap by driving Read Wait or stopping SD clock. If the Read Wait signal is already driven (due to data buffer cannot receive data), the Host Controller can continue to stop read operation by driving the Read Wait signal. It is necessary to support Read Wait in order to use suspend / resume function. (b) In the case of write transactions This status indicates that a write transfer is executing on the SD Bus. Changing this value from 1 to 0 generate a Transfer Complete interrupt in the Normal Interrupt Status register. Refer to Section 3.12.4 for sequence details. This bit shall be set in either of the following cases:<br>• After the end bit of the write command.<br>• When writing to 1 to Continue Request in the Block Gap Control register to continue a write transfer.<br>This bit shall be cleared in either of the following cases:<br>• When the SD card releases write busy of the last data block. If SD card does not drive busy signal for 8 SD Clocks, the Host Controller shall consider the card drive 'Not Busy'. In case of ADMA2, the last block is designated by the last transfer of Descriptor Table.<br>• When the SD card releases write busy prior to waiting for write transfer as a result of a Stop At Block Gap Request.<br>(c) Command with busy This status indicates whether a command indicates busy (ex. erase command for memory) is executing on the SD Bus. This bit is set after the end bit of the command with busy and cleared when busy is de-asserted. Changing this bit from 1 to 0 generate a Transfer Complete interrupt in the Normal Interrupt Status register. Refer Figure 2-11 to Figure 2-13.<br>• 1 = DAT Line Active<br>• 0 = DAT Line Inactive |

| 1 | 0b<br>RO | **Command Inhibit (DAT) (cmd_inhibit_dat):** This status bit is generated if either the DAT Line Active or the Read Transfer Active is set to 1. If this bit is 0, it indicates the Host Controller can issue the next SD Command. Commands with busy signal belong to Command Inhibit (DAT) (ex. R1b, R5b type). Changing from 1 to 0 generates a Transfer Complete interrupt in the Normal Interrupt Status register. **Note:** The SD Host Driver can save registers in the range of 000-00Dh for a suspend transaction after this bit has changed from 1 to 0.<br>• 1 Cannot issue command which uses the DAT line<br>• 0 Can issue command which uses the DAT line |
| 0 | 0b<br>RO | **Command Inhibit (CMD) (cmd_inhibit_cmd):** Command Inhibit (CMD) If this bit is 0, it indicates the CMD line is not in use and the Host Controller can issue a SD Command using the CMD line. cleared when the command response is received. Auto CMD12 and Auto CMD23 consist of two responses. In this case, this bit is not cleared by the response of CMD12 or CMD23 but cleared by the response of a read/write command. Status issuing Auto CMD12 is not read from this bit. So if a command is issued during Auto CMD12 operation, Host Controller shall manage to issue two commands: CMD12 and a command set by Command register. Even if the Command Inhibit (DAT) is set to 1, commands using only the CMD line can be issued if this bit is 0. Changing from 1 to 0 generates a Command Complete Interrupt in the Normal Interrupt Status register. If the Host Controller cannot issue the command because of a command conflict error (Refer to Command CRC Error in Section 2.2.18) or because of Command Not Issued By Auto CMD12 Error (Refer to Section 2.2.23), this bit shall remain 1 and the Command Complete is not set.<br>• 1 Cannot issue command<br>• 0 Can issue command using only CMD line |

|---|---|---|
| 3 | 0b<br>RW | **Interrupt at Block Gap (int_blk_gap):** This bit is valid only in 4-bit mode of the SDIO card and selects a sample point in the interrupt cycle. Setting to 1 enables interrupt detection at the block gap for a multiple block transfer. Setting to 0 disables interrupt detection during a multiple block transfer. If the SD card cannot signal an interrupt during a multiple block transfer, this bit should be set to 0. When the Host Driver detects an SD card insertion, it shall set this bit according to the CCCR of the SDIO card.<br>• 1 = Enabled<br>• 0 = Disabled |
| 2 | 0b<br>RW | **Read Wait Control (rd_wait_ctl):** The read wait function is optional for SDIO cards. If the card supports read wait, set this bit to enable use of the read wait protocol to stop read data using the DAT[2] line. Otherwise, the Host Controller has to stop the SD Clock to hold read data, which restricts commands generation. When the Host Driver detects an SD card insertion, it shall set this bit according to the CCCR of the SDIO card. If the card does not support read wait, this bit shall never be set to 1, otherwise DAT line conflict may occur. If this bit is set to 0, Suspend/Resume cannot be supported.<br>• 1 = Enable Read Wait Control<br>• 0 = Disable Read Wait Control |
| 1 | 0b<br>RW | **Continue Request (cont_req):** This bit is used to restart a transaction, which was stopped using the Stop At Block Gap Request. To cancel stop at the block gap, set Stop At Block Gap Request to 0 and set this bit 1 to restart the transfer. The Host Controller automatically clears this bit in either of the following cases:<br>• In the case of a read transaction, the DAT Line Active changes from 0 to 1 as a read transaction restarts.<br>• In the case of a write transaction, the Write Transfer Active changes from 0 to 1 as the write transaction restarts.<br>Therefore, it is not necessary for Host Driver to set this bit to 0. If Stop At Block Gap Request is set to 1, any write to this bit is ignored.<br>• 1 = Restart<br>• 0 = Not affect |
| 0 | 0b<br>RW | **Stop at Block Gap Request (stp_blk_gap_req):** This bit is used to stop executing read and write transaction at the next block gap for non-DMA, SDMA and ADMA transfers. The Host Driver shall leave this bit set Copyright 2002-2011 SD Association SD Host Controller Simplified Specification Version 3.00 44 to 1 until the Transfer Complete is set to 1. Clearing both Stop At Block Gap Request and Continue Request shall not cause the transaction to restart. When Host Controller version is 1.00, the Host Driver can set this bit if the card supports Read Wait Control. When Host Controller version is 2.00 or later, the Host Driver can set this bit regardless of the card supports Read Wait Control. The Host Controller shall stop read transfer by using Read Wait or stopping SD clock. In case of write transfers in which the Host Driver writes data to the Buffer Data Port register, the Host Driver shall set this bit after all block data is written. If this bit is set to 1, the Host Driver shall not write data to Buffer Data Port register. This bit affects Read Transfer Active, Write Transfer Active, DAT Line Active and Command Inhibit (DAT) in the Present State register. Regarding detailed control of bits D01 and D00, refer to Section 3.8 and 3.12.<br>• 1 = Stop<br>• 0 = Transfer |

## 16.8.16 Wakeup Control Register (WAKEUP_CTL)—Offset 2Bh

This register is mandatory for the Host Controller, but wakeup functionality depends on the Host Controller system hardware and software. The Host Driver shall maintain voltage on the SD Bus, by setting SD Bus Power to 1 in the Power Control register, when wakeup event via Card Interrupt is desired. Wakeup Event is not supported by Host Controller. Sideband wake via GPIO pin and register shall be used instead. During RTD3, GPIO register is readable and GPIO signal is routed to APIC.

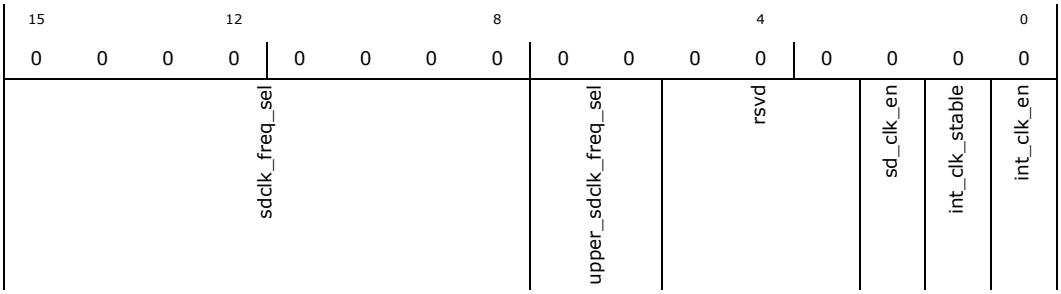
## 16.8.17 Clock Control Register (CLK_CTL)—Offset 2Ch

At the initialization of the Host Controller, the Host Driver shall set the SDCLK Frequency Select according to the Capabilities register.



### Access Method

**Type:** Memory Mapped I/O Register (Size: 16 bits)

| 15:8 | 00h<br>RW | **SDCLK Frequency Select (sdclk_freq_sel):** This register is used to select the frequency of the SDCLK pin. The definition of this field is dependent on the Host Controller Version. **(1) 8-bit Divided Clock Mode** This mode is supported by the Host Controller Version 1.00 and 2.00. The frequency is not programmed directly, rather, this register holds the divisor of the Base Clock Frequency For SD Clock in the capabilities register. Only the following settings are allowed. **(1) 8-bit Divided Clock Mode**<br>• 80h = base clock divided by 256<br>• 40h = base clock divided by 128<br>• 20h = base clock divided by 64<br>• 10h = base clock divided by 32<br>• 08h = base clock divided by 16<br>• 04h = base clock divided by 8<br>• 02h = base clock divided by 4<br>• 01h = base clock divided by 2<br>• 00h = base clock(10MHz and up)<br>Setting 00h specifies the highest frequency of the SD Clock. When setting multiple bits, the most significant bit is used as the divisor, but it should not be set. The three default divider values can be calculated by the frequency that is defined by the Base Clock Frequency For SD Clock in the Capabilities register.<br>• 400KHz divider value<br>• 25MHz divider value<br>• 50MHz divider value<br>According to the Physical Layer Specification, the maximum SD Clock frequency is 25 MHz in normal speed mode and 50MHz in high speed mode, and shall never exceed this limit. The frequency of the SDCLK is set by the following formula: Clock Frequency = (Base Clock) / divisor Thus, choose the smallest possible divisor which results in a clock frequency that is less than or equal to the target frequency. For example, if the Base Clock Frequency For SD Clock in the Capabilities register has the value 33MHz, and the target frequency is 25MHz, then choosing the divisor value of 01h will yield 16.5MHz, which is the nearest frequency less than or equal to the target. Similarly, to approach a clock value of 400KHz, the divisor value of 40h yields the optimal clock value of 258KHz. **(2) 10-bit Divided Clock Mode** Host Controller Version 3.00 supports this mandatory mode instead of the 8-bit Divided Clock Mode. The length of divider is extended to 10 bits, and all divider values shall be supported.<br>• 3FFh = 1/2046 Divided Clock<br>• N = 1/2N Divided Clock (Duty 50%)<br>• 002h = 1/4 Divided Clock<br>• 001h = 1/2 Divided Clock<br>• 000h = Base Clock (10MHz and up)<br>• 3FFh = Base Clock * M / 1024<br>• ..... .....<br>• N - 1 = Base Clock * M / N<br>• ..... .....<br>• 002h = Base Clock * M / 3<br>• 001h = Base Clock * M / 2<br>• 000h = Base Clock * M<br>This field depends on setting of Preset Value Enable in the Host Control 2 register. ## 16.8.20 Normal Interrupt Status Register (NML_INT_STATUS)—Offset 30h

The Normal Interrupt Status Enable affects reads of this register, but Normal Interrupt Signal Enable does not affect these reads. An interrupt is generated when the Normal Interrupt Signal Enable is enabled and at least one of the status bits is set to 1. Writing 1 to a bit of RW1C attribute clears it; writing 0 keeps the bit unchanged. Writing 1 to a bit of ROC attribute keeps the bit unchanged. More than one status can be cleared with a single register write. The Card Interrupt is cleared when the card stops asserting the interrupt; that is, when the Card Driver services the interrupt condition.

| 8 | 0b<br>RO | **Card Interrupt (crd_int):** Writing this bit to 1 does not clear this bit. It is cleared by resetting the SD card interrupt factor. In 1-bit mode, the Host Controller shall detect the Card Interrupt without SD Clock to support wakeup. In 4-bit mode, the card interrupt signal is sampled during the interrupt cycle, so there are some sample delays between the interrupt signal from the SD card and the interrupt to the Host System. When this status has been set and the Host Driver needs to start this interrupt service, Card Interrupt Status Enable in the Normal Interrupt Status Enable register may be set to 0 in order to clear the card interrupt statuses latched in the Host Controller and to stop driving the interrupt signal to the Host System. After completion of the card interrupt service (It should reset interrupt factors in the SD card and the interrupt signal may not be asserted), set Card Interrupt Status Enable to 1 and start sampling the interrupt signal again. Interrupt detected by DAT[1] is supported when there is a card per slot. In case of shared bus, interrupt pins are used to detect interrupts. ## 16.8.21 Error Interrupt Status Register (ERR_INT_STATUS)—Offset 32h

Signals defined in this register can be enabled by the Error Interrupt Status Enable register, but not by the Error Interrupt Signal Enable register. The interrupt is generated when the Error Interrupt Signal Enable is enabled and at least one of the statuses is set to 1. Writing to 1 clears the bit, and writing to 0 keeps the bit unchanged. More than one status can be cleared at the one register write.

If this bit is set to 1, the Host Driver can stop the SDCLK during asynchronous interrupt period to save power. During this period, the Host Controller continues to deliver Card Interrupt to the host when it is asserted by the Card. ## 16.8.31 Force Event Register for Error Interrupt Status (FORCE_EVENT_ERR_INT_STAT)—Offset 52h

Error Interrupt Status register can be written. The effect of a write to this address will be reflected in the Error Interrupt Status Register if the corresponding bit of the Error Interrupt Status Enable Register is set.

- Writing 1 : set each bit of the Error Interrupt Status Register
- Writing 0 : no effect

**Note:** By setting this register, the Error Interrupt can be set in the Error Interrupt Status register. In order to generate interrupt signal, both the Error Interrupt Status Enable and Error Interrupt Signal Enable shall be set.

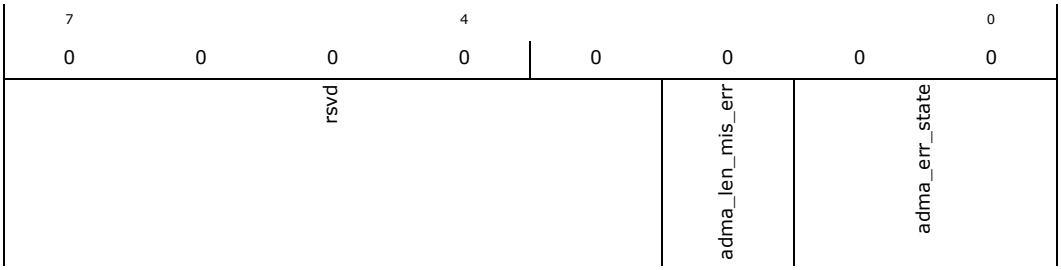
### 16.8.32 ADMA Error Status Register (ADMA_ERR_STAT)—Offset 54h

When ADMA Error Interrupt occurs, the ADMA Error States field in this register holds the ADMA state and the ADMA System Address Register holds the address around the error descriptor. To recover from the error, the Host Driver requires the ADMA state to identify the error descriptor address as follows:

- ST_STOP: Previous location set in the ADMA System Address register is the error descriptor address
- ST_FDS: Current location set in the ADMA System Address register is the error descriptor address
- ST_CADR: This sate is never set because do not generate ADMA error in this state.

- ST_TFR: Previous location set in the ADMA System Address register is the error descriptor address

The Host Controller generates the ADMA Error Interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state. In this case, ADMA Error State indicates that an error occurs at ST_FDS state. The Host Driver may find that the Valid bit is not set in the error descriptor.



### Access Method

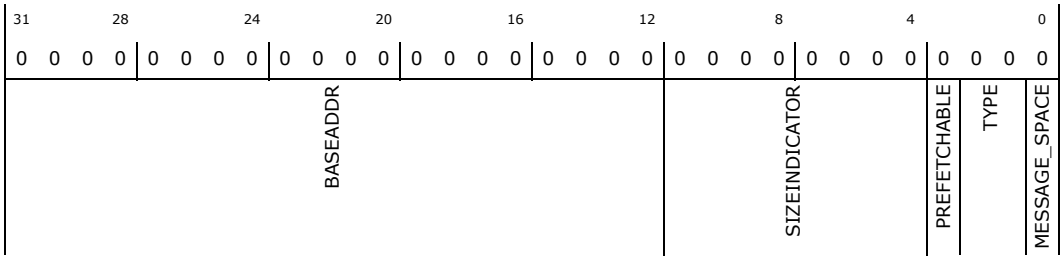
## 16.9.5 Base Address Register (BAR)—Offset 10h



Each AHB device is a single function device with only a single BAR associated with it. Bits 31:4 indicate the Base Address register. Power-up software can determine how much address space the AHB Device requires by writing a value of all 1's to the register and then reading the value back. Bridge will return 0's in all don't-care address bits, effectively specifying the address space required. Unimplemented Base Address registers are hardwired to zero. This is the Size Indicator Read only bits of the register.

### Access Method

**Type:** PCI Configuration Register (Size: 32 bits)

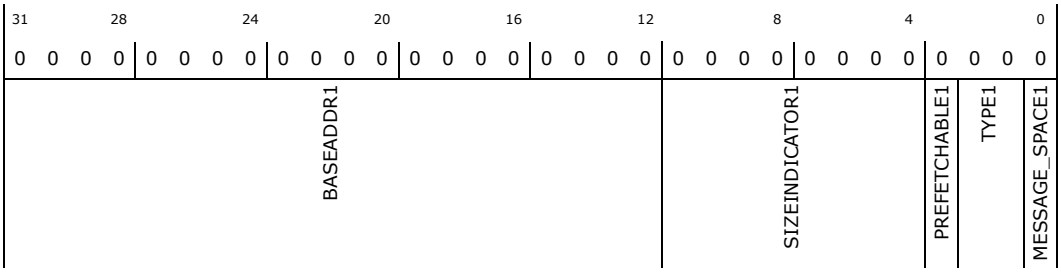
## 16.9.6 Base Address Register 1 (BAR1)—Offset 14h



Memory accesses to BAR1 region access the PCI configuration space for the LPIO device. BAR1 region is always 4K. However SW accesses through BAR1 should only access the regular PCI configuration space. BAR1 memory accesses which do not access a defined PCI configuration register are treated as accesses to a reserved register.

### Access Method

**Type:** PCI Configuration Register (Size: 32 bits)

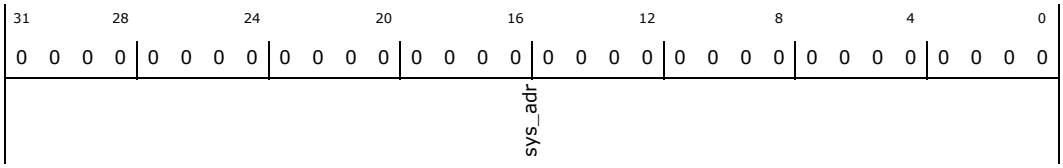
## 16.10.1 SDMA System Address / Argument 2 Register (SYS_ADR)—Offset 0h

This register contains the physical system memory address used for DMA transfers or the second argument for the Auto CMD23.



### Access Method

**Type:** Memory Mapped I/O Register (Size: 32 bits)

**Offset:** [BAR] + 0h

**BAR Type:** PCI Configuration Register (Size: 32 bits)
**BAR Reference:** [B:0, D:23, F:0] + 10h

**Default:** 00000000h

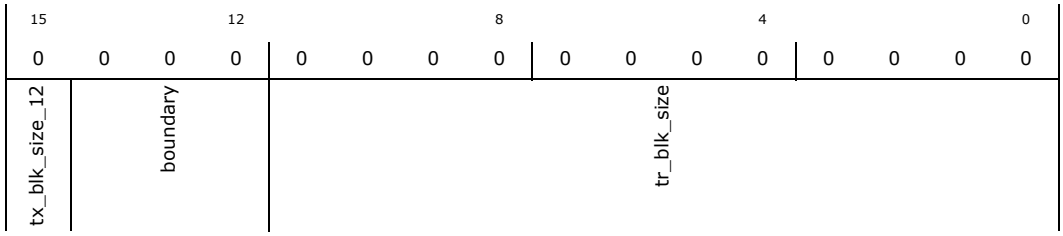
When the Host Controller stops a SDMA transfer, this register shall point to the system address of the next contiguous data position. It can be accessed only if no transaction is executing (i.e., after a transaction has stopped). Read operations during transfers may return an invalid value.<br>The Host Driver shall initialize this register before starting a SDMA transaction. After SDMA has stopped, the next system address of the next contiguous data position can be read from this register.<br>The SDMA transfer waits at each boundary specified by the Host SDMA Buffer Boundary in the Block Size register. The Host Controller generates a DMA Interrupt to request the Host Driver to update this register. The Host Driver sets the next system address of the next data position to this register.<br>When the uppermost byte of this register (003h) is written, the Host Controller restarts the SDMA transfer.<br>When restarting SDMA by the Resume command or by setting Continue Request in the Block Gap Control register, the Host Controller shall start at the next contiguous address stored here in the SDMA System Address register. ADMA does not use this register. **(2) Argument 2**<br>This register is used with the Auto CMD23 to set a 32-bit block count value to the argument of the CMD23 while executing Auto CMD23.<br>If Auto CMD23 is used with ADMA, the full 32-bit block count value can be used. If Auto CMD23 is used without AMDA, the available block count value is limited by the Block Count register. 65535 blocks is the maximum value in this case. |

## 16.10.2 Block Size Register (BLK_SIZE)—Offset 4h

This register is used to configure the number of bytes in a data block.



### Access Method

**Type:** Memory Mapped I/O Register (Size: 16 bits)

**Offset:** [BAR] + 4h

**BAR Type:** PCI Configuration Register (Size: 32 bits)
**BAR Reference:** [B:0, D:23, F:0] + 10h

|---|---|---|
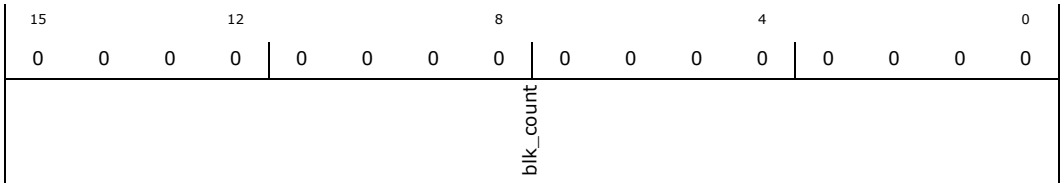
| 14:12 | 000b<br>RW | **Host SDMA Buffer Boundary (boundary):** The large contiguous memory space may not be available in the virtual memory system. To perform long SDMA transfer, SDMA System Address register shall be updated at every system memory boundary during SDMA transfer. These bits specify the size of contiguous buffer in the system memory. The SDMA transfer shall wait at each boundary specified by these fields and the Host Controller generates the DMA Interrupt to request the Host Driver to update the SDMA System Address register. At the end of transfer, the Host Controller may issue or may not issue DMA Interrupt. In particular, DMA Interrupt shall not be issued after Transfer Complete Interrupt is issued. In case of this register is set to 0 (buffer size = 4K bytes), lower 12-bit of byte address points data in the contiguous buffer and the upper 20-bit points the location of the buffer in the system memory. The SDMA transfer stops when the Host Controller detects carry out of the address from bit 11 to 12. These bits shall be supported when the SDMA Support in the Capabilities register is set to 1 and this function is active when the DMA Enable in the Transfer Mode register is set to 1. ADMA does not use this register.<br>• 000b = 4K bytes (Detects A11 carry out)<br>• 001b = 8K bytes (Detects A12 carry out)<br>• 010b = 16K Bytes (Detects A13 carry out)<br>• 011b = 32K Bytes (Detects A14 carry out)<br>• 100b = 64K bytes (Detects A15 carry out)<br>• 101b = 128K Bytes (Detects A16 carry out)<br>• 110b = 256K Bytes (Detects A17 carry out)<br>• 111b = 512K Bytes (Detects A18 carry out) |

It can be accessed only if no transaction is executing (i.e., after a transaction has stopped). Read operations during transfers may return an invalid value, and write operations shall be ignored.<br>• 0800h = 2048 Bytes<br>• . . .<br>• 0200h = 512 Bytes<br>• 01FFh = 511 Bytes<br>• . . .<br>• 0004h = 4 Bytes<br>• 0003h = 3 Bytes<br>• 0002h = 2 Bytes<br>• 0001h = 1 Byte<br>• 0000h = No data transfer |

## 16.10.3 Block Count Register (BLK_COUNT)—Offset 6h

This register is used to configure the number of data blocks.



### Access Method

**Type:** Memory Mapped I/O Register (Size: 16 bits)

**Offset:** [BAR] + 6h

**BAR Type:** PCI Configuration Register (Size: 32 bits)
**BAR Reference:** [B:0, D:23, F:0] + 10h

The Host Driver shall set this register to a value between 1 and the maximum block count. The HC decrements the block count after each block transfer, and stops when the count reaches zero. Setting the block count to 0 results in no data blocks being transferred. This register should be accessed only when no transaction is executing (i.e., after transactions are stopped). During data transfer, read operations on this register may return an invalid value and write operations are ignored. When saving transfer context as a result of a Suspend command, the number of blocks yet to be transferred can be determined by reading this register. When restoring transfer context prior to issuing a Resume command, the HD shall restore the previously saved block count.<br>• 0000h = Stop Count<br>• 0001h = 1 block<br>• 0002h = 2 blocks<br>• . . .<br>• FFFFh = 65535 blocks |

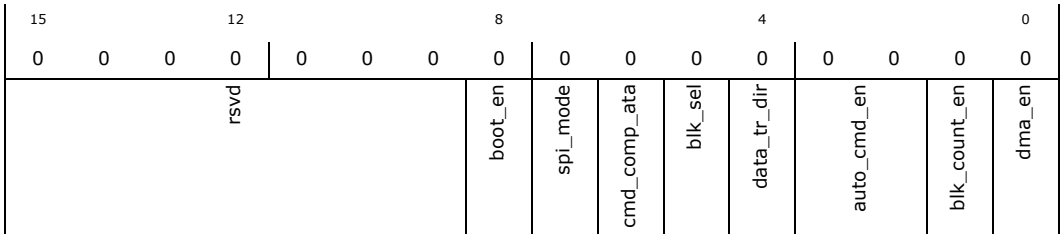
## 16.10.5 Transfer Mode Register (TX_MODE)—Offset Ch

This register is used to control the operation of data transfers. The Host Driver shall set this register before issuing a command which transfers data (Refer to Data Present Select in the Command register), or before issuing a Resume command. The Host Driver shall save the value of this register when the data transfer is suspended (as a result of a Suspend command) and restore it before issuing a Resume command. To prevent data loss, the Host Controller shall implement write protection for this register during data transactions. Writes to this register shall be ignored when the Command Inhibit (DAT) in the Present State register is 1.



### Access Method

**Type:** Memory Mapped I/O Register (Size: 16 bits)

**Offset:** [BAR] + Ch

**BAR Type:** PCI Configuration Register (Size: 32 bits)
**BAR Reference:** [B:0, D:23, F:0] + 10h

| 1 | 0b RW | **Block Count Enable (blk_count_en):** This bit is used to enable the Block Count register, which is only relevant for multiple block transfers. When this bit is 0, the Block Count register is disabled, which is useful in executing an infinite transfer. (Refer to Table 2-8). If ADMA2 data transfer is more than 65535 blocks, this bit shall be set to 0. In this case, data transfer length is designated by Descriptor Table.<br>• 1 = Enable<br>• 0 = Disable |
| 0 | 0b RW | **DMA Enable (dma_en):** This bit enables DMA functionality as described in section 1.4. DMA can be enabled only if it is supported as indicated in the Capabilities register. One of the DMA modes can be selected by DMA Select in the Host Control register. If DMA is not supported, this bit is meaningless and shall always read 0. If this bit is set to 1, a DMA operation shall begin when the Host Driver writes to the upper byte of Command register (00Fh).<br>• 1 = DMA Data transfer<br>• 0 = No data transfer or Non DMA data transfer |

## 16.10.6 Command Register (CMD)—Offset Eh

The Host Driver shall check the Command Inhibit (DAT) bit and Command Inhibit (CMD) bit in the Present State register before writing to this register. Writing to the upper byte of this register triggers SD command generation. The Host Driver has the responsibility to write this register because the Host Controller does not protect for writing when Command Inhibit (CMD) is set.

| 7:6 | 00b<br>RW | **Command Type (cmd_type):** There are three types of special commands: Suspend, Resume and Abort. These bits shall be set to 00b for all other commands. **(1) Suspend Command** If the Suspend command succeeds, the Host Controller shall assume the SD Bus has been released and that it is possible to issue the next command, which uses the DAT line. The Host Controller shall de-assert Read Wait for read transactions and stop checking busy for write transactions. The interrupt cycle shall start, in 4-bit mode. If the Suspend command fails, the Host Controller shall maintain its current state, and the Host Driver shall restart the transfer by setting Continue Request in the Block Gap Control register. (Refer to 3.12.1 Suspend Sequence). **(2) Resume Command** The Host Driver re-starts the data transfer by restoring the registers in the range of 000-00Dh. (Refer to Figure 1-4 in section 1.6 for the register map.) The Host Controller shall check for busy before starting write transfers. **(3) Abort Command** If this command is set when executing a read transfer, the Host Controller shall stop reads to the buffer. If this command is set when executing a write transfer, the Host Controller shall stop driving the DAT line. After issuing the Abort command, the Host Driver should issue a software reset. (Refer to 3.8 Abort Transaction).<br>• 11b = Abort -- CMD12, CMD52 for writing 'I/O Abort' in CCCR<br>• 10b = Resume -- CMD52 for writing 'Function Select' in CCCR<br>• 01b = Suspend -- CMD52 for writing 'Bus Suspend' in CCCR<br>• 00b = Normal -- Other commands |

| 16 | 1b<br>RO | **Card Inserted (crd_ins):** This bit indicates whether a card has been inserted. The Host Controller shall debounce this signal so that the Host Driver will not need to wait for it to stabilize. Changing from 0 to 1 generates a Card Insertion interrupt in the Normal Interrupt Status register and changing from 1 to 0 generates a Card Removal interrupt in the Normal Interrupt Status register. The Software Reset For All in the Software Reset register shall not affect this bit. If a card is removed while its power is on and its clock is oscillating, the Host Controller shall clear SD Bus Power in the Power Control register (Refer to Section 2.2.11) and SD Clock Enable in the Clock Control register (Refer to Section 2.2.14). When this bit is changed from 1 to 0, the Host Controller shall immediately stop driving CMD and DAT[3:0] (tri-state). A change of this bit from 1 to 0 occurs when all the block data is read from the buffer. A change of this bit from 0 to 1 occurs when block data is ready in the buffer and generates the Buffer Read Ready interrupt.<br>• 1 = Read enable<br>• 0 = Read disable |
| 10 | 0b<br>RO | **Buffer Write Enable (buf_wr_en):** This status is used for non-DMA write transfers. The Host Controller can implement multiple buffers to transfer data efficiently. This read only flag indicates if space is available for write data. If this bit is 1, data can be written to the buffer. A change of this bit from 1 to 0 occurs when all the block data is written to the buffer. A change of this bit from 0 to 1 occurs when top of block data can be written to the buffer and generates the Buffer Write Ready interrupt. The Host Controller should neither set Buffer Write Enable nor generate Buffer Write Ready Interrupt after the last block data is written to the Buffer Data Port Register.<br>• 1 = Write enable<br>• 0 = Write disable |
| 9 | 0b<br>RO | **Read Transfer Active (rd_tx_active):** This status is used for detecting completion of a read transfer. Refer to Section 3.12.3 for sequence details. (a) In the case of read transactions This status indicates whether a read transfer is executing on the SD Bus. Changing this value from 1 to 0 generates a Block Gap Event interrupt in the Normal Interrupt Status register, as the result of the Stop At Block Gap Request being set. Refer to Section 3.12.3 for details on timing. This bit shall be set in either of the following cases:<br>• After the end bit of the read command.<br>• When writing a 1 to Continue Request in the Block Gap Control register to restart a read transfer.<br>This bit shall be cleared in either of the following cases:<br>• When the end bit of the last data block is sent from the SD Bus to the Host Controller. In case of ADMA2, the last block is designated by the last transfer of Descriptor Table.<br>• When a read transfer is stopped at the block gap initiated by a Stop At Block Gap Request.<br>The Host Controller shall stop read operation at the start of the interrupt cycle of the next block gap by driving Read Wait or stopping SD clock. If the Read Wait signal is already driven (due to data buffer cannot receive data), the Host Controller can continue to stop read operation by driving the Read Wait signal. It is necessary to support Read Wait in order to use suspend / resume function. (b) In the case of write transactions This status indicates that a write transfer is executing on the SD Bus. Changing this value from 1 to 0 generate a Transfer Complete interrupt in the Normal Interrupt Status register. Refer to Section 3.12.4 for sequence details. This bit shall be set in either of the following cases:<br>• After the end bit of the write command.<br>• When writing to 1 to Continue Request in the Block Gap Control register to continue a write transfer.<br>This bit shall be cleared in either of the following cases:<br>• When the SD card releases write busy of the last data block. If SD card does not drive busy signal for 8 SD Clocks, the Host Controller shall consider the card drive 'Not Busy'. In case of ADMA2, the last block is designated by the last transfer of Descriptor Table.<br>• When the SD card releases write busy prior to waiting for write transfer as a result of a Stop At Block Gap Request.<br>(c) Command with busy This status indicates whether a command indicates busy (ex. erase command for memory) is executing on the SD Bus. This bit is set after the end bit of the command with busy and cleared when busy is de-asserted. Changing this bit from 1 to 0 generate a Transfer Complete interrupt in the Normal Interrupt Status register. Refer Figure 2-11 to Figure 2-13.<br>• 1 = DAT Line Active<br>• 0 = DAT Line Inactive |

| 1 | 0b<br>RO | **Command Inhibit (DAT) (cmd_inhibit_dat):** This status bit is generated if either the DAT Line Active or the Read Transfer Active is set to 1. If this bit is 0, it indicates the Host Controller can issue the next SD Command. Commands with busy signal belong to Command Inhibit (DAT) (ex. R1b, R5b type). Changing from 1 to 0 generates a Transfer Complete interrupt in the Normal Interrupt Status register. **Note:** The SD Host Driver can save registers in the range of 000-00Dh for a suspend transaction after this bit has changed from 1 to 0.<br>• 1 Cannot issue command which uses the DAT line<br>• 0 Can issue command which uses the DAT line |
| 0 | 0b<br>RO | **Command Inhibit (CMD) (cmd_inhibit_cmd):** Command Inhibit (CMD) If this bit is 0, it indicates the CMD line is not in use and the Host Controller can issue a SD Command using the CMD line. cleared when the command response is received. Auto CMD12 and Auto CMD23 consist of two responses. In this case, this bit is not cleared by the response of CMD12 or CMD23 but cleared by the response of a read/write command. Status issuing Auto CMD12 is not read from this bit. So if a command is issued during Auto CMD12 operation, Host Controller shall manage to issue two commands: CMD12 and a command set by Command register. Even if the Command Inhibit (DAT) is set to 1, commands using only the CMD line can be issued if this bit is 0. Changing from 1 to 0 generates a Command Complete Interrupt in the Normal Interrupt Status register. If the Host Controller cannot issue the command because of a command conflict error (Refer to Command CRC Error in Section 2.2.18) or because of Command Not Issued By Auto CMD12 Error (Refer to Section 2.2.23), this bit shall remain 1 and the Command Complete is not set.<br>• 1 Cannot issue command<br>• 0 Can issue command using only CMD line |

|---|---|---|
| 3 | 0b<br>RW | **Interrupt at Block Gap (int_blk_gap):** This bit is valid only in 4-bit mode of the SDIO card and selects a sample point in the interrupt cycle. Setting to 1 enables interrupt detection at the block gap for a multiple block transfer. Setting to 0 disables interrupt detection during a multiple block transfer. If the SD card cannot signal an interrupt during a multiple block transfer, this bit should be set to 0. When the Host Driver detects an SD card insertion, it shall set this bit according to the CCCR of the SDIO card.<br>• 1 = Enabled<br>• 0 = Disabled |
| 2 | 0b<br>RW | **Read Wait Control (rd_wait_ctl):** The read wait function is optional for SDIO cards. If the card supports read wait, set this bit to enable use of the read wait protocol to stop read data using the DAT[2] line. Otherwise, the Host Controller has to stop the SD Clock to hold read data, which restricts commands generation. When the Host Driver detects an SD card insertion, it shall set this bit according to the CCCR of the SDIO card. If the card does not support read wait, this bit shall never be set to 1, otherwise DAT line conflict may occur. If this bit is set to 0, Suspend/Resume cannot be supported.<br>• 1 = Enable Read Wait Control<br>• 0 = Disable Read Wait Control |
| 1 | 0b<br>RW | **Continue Request (cont_req):** This bit is used to restart a transaction, which was stopped using the Stop At Block Gap Request. To cancel stop at the block gap, set Stop At Block Gap Request to 0 and set this bit 1 to restart the transfer. The Host Controller automatically clears this bit in either of the following cases:<br>• In the case of a read transaction, the DAT Line Active changes from 0 to 1 as a read transaction restarts.<br>• In the case of a write transaction, the Write Transfer Active changes from 0 to 1 as the write transaction restarts.<br>Therefore, it is not necessary for Host Driver to set this bit to 0. If Stop At Block Gap Request is set to 1, any write to this bit is ignored.<br>• 1 = Restart<br>• 0 = Not affect |
| 0 | 0b<br>RW | **Stop at Block Gap Request (stp_blk_gap_req):** This bit is used to stop executing read and write transaction at the next block gap for non-DMA, SDMA and ADMA transfers. The Host Driver shall leave this bit set Copyright 2002-2011 SD Association SD Host Controller Simplified Specification Version 3.00 44 to 1 until the Transfer Complete is set to 1. Clearing both Stop At Block Gap Request and Continue Request shall not cause the transaction to restart. When Host Controller version is 1.00, the Host Driver can set this bit if the card supports Read Wait Control. When Host Controller version is 2.00 or later, the Host Driver can set this bit regardless of the card supports Read Wait Control. The Host Controller shall stop read transfer by using Read Wait or stopping SD clock. In case of write transfers in which the Host Driver writes data to the Buffer Data Port register, the Host Driver shall set this bit after all block data is written. If this bit is set to 1, the Host Driver shall not write data to Buffer Data Port register. This bit affects Read Transfer Active, Write Transfer Active, DAT Line Active and Command Inhibit (DAT) in the Present State register. Regarding detailed control of bits D01 and D00, refer to Section 3.8 and 3.12.<br>• 1 = Stop<br>• 0 = Transfer |

### 16.10.16 Wakeup Control Register (WAKEUP_CTL)—Offset 2Bh

This register is mandatory for the Host Controller, but wakeup functionality depends on the Host Controller system hardware and software. The Host Driver shall maintain voltage on the SD Bus, by setting SD Bus Power to 1 in the Power Control register, when wakeup event via Card Interrupt is desired. Wakeup Event is not supported by Host Controller. Sideband wake via GPIO pin and register shall be used instead. During RTD3, GPIO register is readable and GPIO signal is routed to APIC.

The definition of this field is dependent on the Host Controller Version. **(1) 8-bit Divided Clock Mode** This mode is supported by the Host Controller Version 1.00 and 2.00. The frequency is not programmed directly, rather, this register holds the divisor of the Base Clock Frequency For SD Clock in the capabilities register. Only the following settings are allowed. **(1) 8-bit Divided Clock Mode**<br>• 80h = base clock divided by 256<br>• 40h = base clock divided by 128<br>• 20h = base clock divided by 64<br>• 10h = base clock divided by 32<br>• 08h = base clock divided by 16<br>• 04h = base clock divided by 8<br>• 02h = base clock divided by 4<br>• 01h = base clock divided by 2<br>• 00h = base clock(10MHz and up)<br>Setting 00h specifies the highest frequency of the SD Clock. When setting multiple bits, the most significant bit is used as the divisor, but it should not be set. The three default divider values can be calculated by the frequency that is defined by the Base Clock Frequency For SD Clock in the Capabilities register.<br>• 400KHz divider value<br>• 25MHz divider value<br>• 50MHz divider value<br>According to the Physical Layer Specification, the maximum SD Clock frequency is 25 MHz in normal speed mode and 50MHz in high speed mode, and shall never exceed this limit. The frequency of the SDCLK is set by the following formula: Clock Frequency = (Base Clock) / divisor Thus, choose the smallest possible divisor which results in a clock frequency that is less than or equal to the target frequency. For example, if the Base Clock Frequency For SD Clock in the Capabilities register has the value 33MHz, and the target frequency is 25MHz, then choosing the divisor value of 01h will yield 16.5MHz, which is the nearest frequency less than or equal to the target. Similarly, to approach a clock value of 400KHz, the divisor value of 40h yields the optimal clock value of 258KHz. **(2) 10-bit Divided Clock Mode** Host Controller Version 3.00 supports this mandatory mode instead of the 8-bit Divided Clock Mode. The length of divider is extended to 10 bits, and all divider values shall be supported.<br>• 3FFh = 1/2046 Divided Clock<br>• N = 1/2N Divided Clock (Duty 50%)<br>• 002h = 1/4 Divided Clock<br>• 001h = 1/2 Divided Clock<br>• 000h = Base Clock (10MHz and up)<br>• 3FFh = Base Clock * M / 1024<br>• ..... .....<br>• N - 1 = Base Clock * M / N<br>• ..... .....<br>• 002h = Base Clock * M / 3<br>• 001h = Base Clock * M / 2<br>• 000h = Base Clock * M<br>This field depends on setting of Preset Value Enable in the Host Control 2 register. If Preset Value Enable = 0, this field is set by Host Driver. If the Preset Value Enable = 1, this field is automatically set to a value specified in one of Preset Value registers. |

## 16.10.20 Normal Interrupt Status Register (NML_INT_STATUS)—Offset 30h

The Normal Interrupt Status Enable affects reads of this register, but Normal Interrupt Signal Enable does not affect these reads. An interrupt is generated when the Normal Interrupt Signal Enable is enabled and at least one of the status bits is set to 1. Writing 1 to a bit of RW1C attribute clears it; writing 0 keeps the bit unchanged. Writing 1 to a bit of ROC attribute keeps the bit unchanged. More than one status can be cleared with a single register write. The Card Interrupt is cleared when the card stops asserting the interrupt; that is, when the Card Driver services the interrupt condition.

| 8 | 0b<br>RO | **Card Interrupt (crd_int):** Writing this bit to 1 does not clear this bit. It is cleared by resetting the SD card interrupt factor. In 1-bit mode, the Host Controller shall detect the Card Interrupt without SD Clock to support wakeup. In 4-bit mode, the card interrupt signal is sampled during the interrupt cycle, so there are some sample delays between the interrupt signal from the SD card and the interrupt to the Host System. When this status has been set and the Host Driver needs to start this interrupt service, Card Interrupt Status Enable in the Normal Interrupt Status Enable register may be set to 0 in order to clear the card interrupt statuses latched in the Host Controller and to stop driving the interrupt signal to the Host System. After completion of the card interrupt service (It should reset interrupt factors in the SD card and the interrupt signal may not be asserted), set Card Interrupt Status Enable to 1 and start sampling the interrupt signal again. Interrupt detected by DAT[1] is supported when there is a card per slot. In case of shared bus, interrupt pins are used to detect interrupts. ## 16.10.21 Error Interrupt Status Register (ERR_INT_STATUS)—Offset 32h

Signals defined in this register can be enabled by the Error Interrupt Status Enable register, but not by the Error Interrupt Signal Enable register. The interrupt is generated when the Error Interrupt Signal Enable is enabled and at least one of the statuses is set to 1. Writing to 1 clears the bit, and writing to 0 keeps the bit unchanged. More than one status can be cleared at the one register write.

If this bit is set to 1, the Host Driver can stop the SDCLK during asynchronous interrupt period to save power. During this period, the Host Controller continues to deliver Card Interrupt to the host when it is asserted by the Card. Usage: It is recommended that Synchronous Interrupt mode be used for SDIO Controller by setting this be to '0'. If Asynchronous Interrupt Enable mode is used, it is required that this bit remain '0' until SD initialization sequence is complete.<br>• 1 = Enabled<br>• 0 = Disabled |

## 16.10.31 Force Event Register for Error Interrupt Status (FORCE_EVENT_ERR_INT_STAT)—Offset 52h

Error Interrupt Status register can be written. The effect of a write to this address will be reflected in the Error Interrupt Status Register if the corresponding bit of the Error Interrupt Status Enable Register is set.

- Writing 1 : set each bit of the Error Interrupt Status Register
- Writing 0 : no effect

**Note:** By setting this register, the Error Interrupt can be set in the Error Interrupt Status register. In order to generate interrupt signal, both the Error Interrupt Status Enable and Error Interrupt Signal Enable shall be set.

## 16.10.32 ADMA Error Status Register (ADMA_ERR_STAT)—Offset 54h

When ADMA Error Interrupt occurs, the ADMA Error States field in this register holds the ADMA state and the ADMA System Address Register holds the address around the error descriptor. To recover from the error, the Host Driver requires the ADMA state to identify the error descriptor address as follows:

- ST_STOP: Previous location set in the ADMA System Address register is the error descriptor address
- ST_FDS: Current location set in the ADMA System Address register is the error descriptor address
- ST_CADR: This sate is never set because do not generate ADMA error in this state.

- ST_TFR: Previous location set in the ADMA System Address register is the error descriptor address

The Host Controller generates the ADMA Error Interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state. In this case, ADMA Error State indicates that an error occurs at ST_FDS state. The Host Driver may find that the Valid bit is not set in the error descriptor.

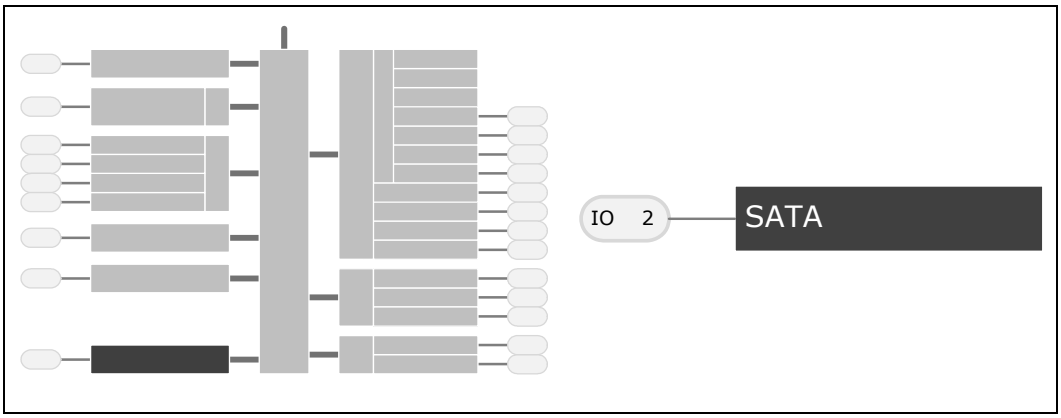
# 17 Serial ATA (SATA)

The SoC has one integrated SATA host controller that supports independent DMA operation on up to 2 ports and supports data transfer rates of 1.5 Gb/s (150 MB/s) and 3.0 Gb/s (300 MB/s). The SATA controller contains two modes of operation—a legacy mode using I/O space, and an AHCI mode using memory space. Software that uses legacy mode will not have AHCI capabilities.



The SoC supports the Serial ATA Specification, Revision 2.6. The SoC also supports several optional sections of the SATA Revision 2.0 Specifications: Extensions to Serial ATA 1.0 Specification, Revision 1.0 (AHCI support is required for some elements).

The SATA controllers feature two sets of interface signals (ports) that can be independently enabled or disabled (they cannot be tri-stated or driven low). Each interface is supported by an independent DMA controller.

The SATA controllers interact with an attached mass storage device through a register interface that is equivalent to that presented by a traditional IDE host adapter. The host software follows existing standards and conventions when accessing the register interface and follows standard command protocol conventions.

***Note 1.*** SATA DevSlp (**Device Sleep**) is not part of revision 2.6 of the SATA specification, with which this processor is compliant. As such, any DEVSLP functionality of this processor is not specification compliant and should not be used.

***Note 2.*** SATA interface transfer rates are independent of UDMA mode settings. SATA interface transfer rates will operate at the bus's maximum speed, regardless of the UDMA mode reported by the SATA device or the system BIOS.

## 17.1 Signal Descriptions

Please see Chapter 2, "Physical Interfaces" for additional details.

The signal description table has the following headings:

- **Signal Name:** The name of the signal/pin
- **Direction**: The buffer direction can be either input, output, or I/O (bidirectional)
- **Platform Power**: The reference power plane.
- **Description**: A brief explanation of the signal's function

**Table 190. Signals**

| Signal Name | Direction Plat. Power | Description |
|---|---|---|
| **SATA_GP[0]** | I V1P8S | **Serial ATA 0 General Purpose:** This is an input pin which can be configured as an interlock switch or as a general purpose I/O, depending on the platform. When used as an interlock switch status indication, this signal should be driven to '0' to indicate that the switch is closed, and to '1' to indicate that the switch is open. |
| **SATA_GP[1]** | I V1P8S | **Serial ATA 1 General Purpose:** Same as above. |
| **SATA_LED#** | O V1P8S | **Serial ATA LED:** This is an open-collector output pin driven during SATA command activity. It is to be connected to external circuitry that can provide the current to drive a platform LED. When active, the LED is on. When tristated, the LED is off. |
| **SATA_TXP[1:0] SATA_TXN[1:0]** | O VPCIESATA | **Serial ATA Port 1 and 0:** These are outbound high-speed differential signals to Port 1 and 0. |
| **SATA_RXP[1:0] SATA_RXN[1:0]** | I VPCIESATA | **Serial ATA Port 1 and 0:** These are inbound high-speed differential signals to Port 1 and 0. |
| **SATA_RCOMP_P SATA_RCOMP_N** | O | These pins are used to connect the external resistors used for Rcomp. Please contact your Intel representative for details. |

# 17.2 Features

## 17.2.1 Supported Features

**Table 191. SATA Feature List (Sheet 1 of 2)**

| Feature | Description |
|---|---|
| Native Command Queuing (NCQ) | Allows the device to reorder commands for more efficient data transfers |
| Auto Activate for DMA | Collapses a DMA Setup then DMA Activate sequence into a DMA Setup only |
| Hot Plug Support | Allows for device detection without power being applied and ability to connect and disconnect devices without prior notification to the system |
| Asynchronous Signal Recovery | Provides a recovery from a loss of signal or establishing communication after hot plug |
| 3 Gb/s Transfer Rate | Capable of data transfers up to 3 Gb/s |
| ATAPI Asynchronous Notification | A mechanism for a device to send a notification to the host that the device requires attention |

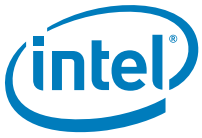


**Table 191. SATA Feature List (Sheet 2 of 2)**

| Feature | Description |
|---|---|
| Host & Link Initiated Power Management | Capability for the host controller or device to request Partial and Slumber interface power states |
| Staggered Spin-Up | Enables the host to spin up hard drives sequentially to prevent power load problems on boot |
| Command Completion Coalescing | Reduces interrupt and completion overhead by allowing a specified number of commands to complete and then generating an interrupt to process the commands |

**Table 192. SATA/AHCI Feature Matrix**

| Feature | AHCI Disabled | AHCI Enabled |
|---|---|---|
| Native Command Queuing (NCQ) | N/A | Supported |
| Auto Activate for DMA | N/A | Supported |

## 17.2.2 Theory of Operation

### 17.2.2.1 Standard ATA Emulation

The SoC contains a set of registers that shadow the contents of the legacy IDE registers. The behavior of the Command and Control Block registers, PIO, and DMA data transfers, resets, and interrupts are all emulated.

***Note:*** The SoC will assert INTR when the master device completes the EDD command regardless of the command completion status of the slave device. If the master completes EDD first, an INTR is generated and BSY will remain '1' until the slave completes the command. If the slave completes EDD first, BSY will be '0' when the master completes the EDD command and asserts INTR. Software must wait for busy to clear (0) before completing an EDD command, as required by the ATA5 through ATA7 (T13) industry standards.

### 17.2.2.2 48-Bit LBA Operation

The SATA host controller supports 48-bit LBA through the host-to-device register FIS when accesses are performed using writes to the task file. The SATA host controller will ensure that the correct data is put into the correct byte of the host-to-device FIS.

There are special considerations when reading from the task file to support 48-bit LBA operation. Software may need to read all 16-bits. Since the registers are only 8-bits wide and act as a FIFO, a bit must be set in the device/control register, which is at offset 3F6h for primary and 376h for secondary (or their native counterparts).

If software clears Bit 7 of the control register before performing a read, the last item written will be returned from the FIFO. If software sets Bit 7 of the control register before performing a read, the first item written will be returned from the FIFO.

### 17.2.3 AHCI Operation

The SoC provides hardware support for Advanced Host Controller Interface (AHCI), a programming interface for SATA host controllers developed through a joint industry effort. AHCI defines transactions between the SATA controller and software and enables advanced performance and usability with SATA. Platforms supporting AHCI may take advantage of performance features such as no master/slave designation for SATA devices—each device is treated as a master—and hardware assisted native command queuing. AHCI also provides usability enhancements such as Hot-Plug. AHCI requires appropriate software support (such as, an AHCI driver) and for some features, hardware support in the SATA device or additional platform hardware.

The SoC supports all of the mandatory features of the *Serial ATA Advanced Host Controller Interface Specification*, Revision 1.3 and many optional features, such as hardware assisted native command queuing, aggressive power management, LED indicator support, and Hot-Plug through the use of interlock switch support (additional platform hardware and software may be required depending upon the implementation).

***Note:*** For reliable device removal notification while in AHCI operation without the use of interlock switches (surprise removal), interface power management should be disabled for the associated port.

## 17.5.1 Identifiers (ID)—Offset 0h

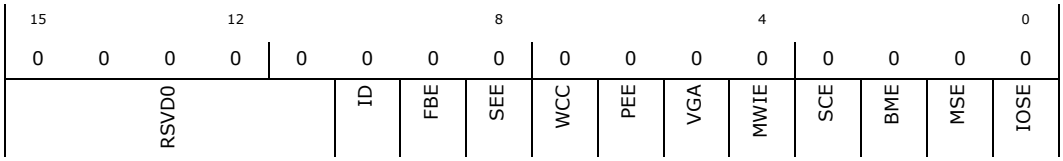
### Access Method

**Type:** PCI Configuration Register (Size: 32 bits)

**ID:** [B:0, D:19, F:0] + 0h

**Default:** 0F208086h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31:16 | 0F20h RO | **Device ID (DID):** The specific value is dependent on config bits and fuses. The value is product specific. VLV SATA DID can be within the range of 0F20-0F27 and 0F2E and 0F2F. However, since VLV SATA does not support RAID, DID can be either 0F20 or OF22. |
| 15:0 | 8086h RO | **Vendor ID (VID):** 16-bit field which indicates the company vendor as Intel. |



## 17.5.2 Command (CMD)—Offset 4h

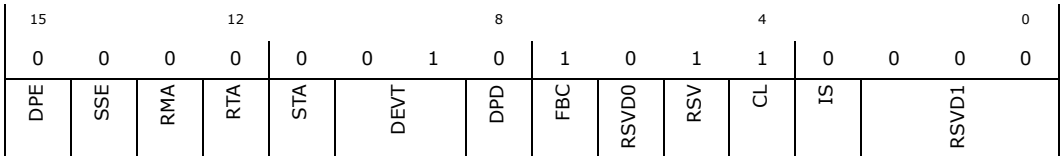
### Access Method

**Type:** PCI Configuration Register (Size: 16 bits)

**CMD:** [B:0, D:19, F:0] + 4h

**Default:** 0000h

| Bit Range | Default & Access | Description |
|---|---|---|
| 15:11 | 0b RO | **RSVD0:** Reserved |
| 10 | 0h RW | **Interrupt Disable (ID):** This disables pin-based INTx# interrupts. This bit has no effect on MSI operation. When set, internal INTx# will not be generated. When cleared, internal INTx# is generated if there is an interrupt and MSI is not enabled. |
| 9 | 0h RO | **Fast Back-to-Back Enable (FBE):** Reserved. |
| 8 | 0h RW | **SERR# Enable (SEE):** When set to 1, the HBA is allowed to generate SERR# on DPD or SATAGC.URD event that is enabled for SERR# generation. When cleared to 0, it is not. |
| 7 | 0h RO | **Wait Cycle Enable (WCC):** Reserved. |
| 6 | 0h RW | **Parity Error Response Enable (PEE):** When set, the SATA Controller will corrupt the outbound DATA FIS CRC if a forwarded data parity error is indicated. |
| 5 | 0h RO | **VGA Palette Snooping Enable (VGA):** Reserved. |
| 4 | 0h RO | **Memory Write and Invalidate Enable (MWIE):** Reserved. |
| 3 | 0h RO | **Special Cycle Enable (SCE):** Reserved. |
| 2 | 0h RW | **Bus Master Enable (BME):** Controls the SATA Controller's ability to act as a master for data transfers. This bit does not impact the generation of completions for split transaction commands. |
| 1 | 0h RW | **Memory Space Enable (MSE):** Controls access to the SATA Controller's target memory space (for AHCI). |
| 0 | 0h RW | **I/O Space Enable (IOSE):** Controls access to the SATA Controller's target I/O space. |



## 17.5.3 Device Status (STS)—Offset 6h

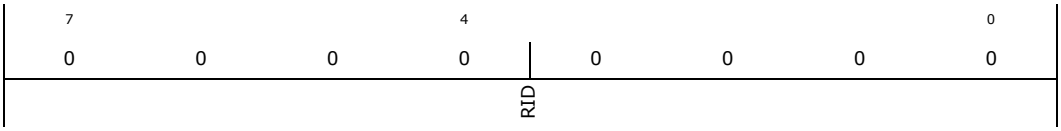
### Access Method

**Type:** PCI Configuration Register (Size: 16 bits)

**STS:** [B:0, D:19, F:0] + 6h

**Default:** 02B0h

| Bit Range | Default & Access | Description |
|---|---|---|
| 15 | 0h RW/1C | **Detected Parity Error (DPE):** Set when the SATA Controller detects a parity error on its interface. |
| 14 | 0h RW/1C | **Signaled System Error (SSE):** Set when SATA Controller generates an SERR#. |
| 13 | 0h RW/1C | **Received Master-Abort Status (RMA):** Set when the SATA Controller receives a master abort to a cycle it generated. |
| 12 | 0h RW/1C | **Received Target-Abort Status (RTA):** Set when the SATA Controller receives a target abort to a cycle it generated. |
| 11 | 0h RW/1C | **Signaled Target-Abort Status (STA):** This bit must be set by a target device whenever it terminates a transaction with Target-Abort. Devices that will never signal Target-Abort do not need to implement this bit. |
| 10:9 | 1h RO | **DEVSEL# Timing Status (DEVT):** Controls the device select time for the SATA Controller's PCI interface. |
| 8 | 0h RW/1C | **Master Data Parity Error Detected (DPD):** Set when the SATA Controller, as a master, either detects a parity error or sees the parity error line asserted, and the parity error response bit (bit 6 of the command register) is set. This bit can only be set on read completions received from the backbone where there is a parity error. |
| 7 | 1h RO | **Fast Back-to-Back Capable (FBC):** Reserved. |
| 6 | 0b RO | **RSVD0:** Reserved |
| 5 | 1h RO | **66 MHz Capable (RSV):** Reserved. |
| 4 | 1h RO | **Capabilities List (CL):** Indicates the presence of a capabilities list. The minimum requirement for the capabilities list must be PCI power management for the SATA Controller. |
| 3 | 0h RO | **Interrupt Status (IS):** Reflects the state of INTx# messages, IRQ14 or IRQ15. This bit is set when the interrupt is to be asserted. This bit is a 0 after the interrupt is cleared |
| 2:0 | 0b RO | **RSVD1:** Reserved |



## 17.5.4 Revision ID (RID)—Offset 8h

### Access Method

**Type:** PCI Configuration Register (Size: 8 bits)

**RID:** [B:0, D:19, F:0] + 8h

**Default:** 00h

| Bit Range | Default & Access | Description |
|---|---|---|
| 7:0 | 00h RO | **Revision ID (RID):** Indicates stepping of the host controller hardware. |

## 17.5.5 Programming Interface (PI)—Offset 9h

This register definition depends on the CC.SCC field. When the CC.SCC is 01h(IDE mode), register definition corresponds to 1st table. When CC.SCC is 06h(AHCI mode), register definition follows the 2nd table.

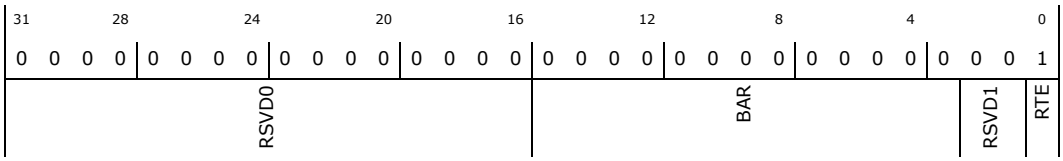
## 17.5.10 Primary Command Block Base Address (PCMDBA)—Offset 10h



This 8-byte I/O space is used in Native Mode for the Primary Controller's Command Block.

### Access Method

**Type:** PCI Configuration Register (Size: 32 bits)

**PCMDBA:** [B:0, D:19, F:0] + 10h

**Default:** 00000001h

| Bit Range | Default & Access | Description |

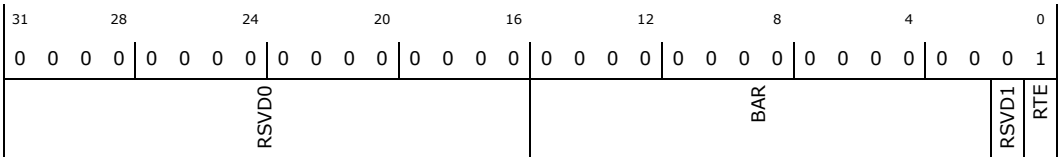
## 17.5.11 Primary Control Block Base Address (PCTLBA)—Offset 14h



This 4-byte I/O space is used in Native Mode for the Primary Controller's Control Block.

### Access Method

**Type:** PCI Configuration Register (Size: 32 bits)

**PCTLBA:** [B:0, D:19, F:0] + 14h

**Default:** 00000001h

| Bit Range | Default & Access | Description |

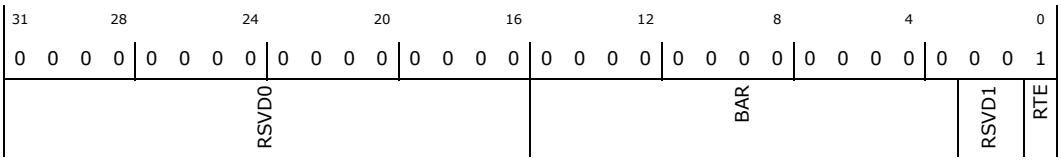
## 17.5.12 Secondary Command Block Base Address (SCMDBA)—Offset 18h



This 8-byte I/O space is used in Native Mode for the Secondary Controller's Command Block.

### Access Method

**Type:** PCI Configuration Register (Size: 32 bits)

**SCMDBA:** [B:0, D:19, F:0] + 18h

**Default:** 00000001h

| Bit Range | Default & Access | Description |

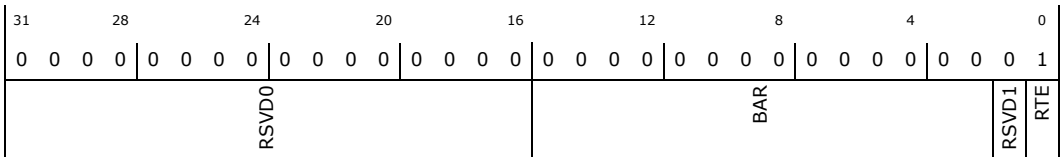
## 17.5.13 Secondary Control Block Base Address (SCTLBA)—Offset 1Ch



This 4-byte I/O space is used in Native Mode for the Secondary Controller's Control Block.

### Access Method

**Type:** PCI Configuration Register (Size: 32 bits)

**SCTLBA:** [B:0, D:19, F:0] + 1Ch

**Default:** 00000001h

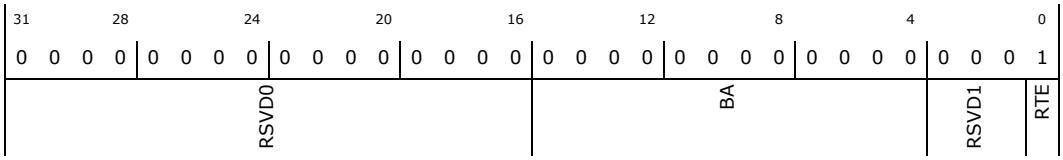
## 17.5.14 Legacy IDE Base Address / AHCI Index Data Pair Base Address (LBAR)—Offset 20h



This BAR is used to allocate I/O space for the SFF-8038i mode of operation (aka Bus Master IDE) and if CC.SCC is not 01h, it is used to allocate I/O space for the AHCI index/data pair mechanism as well. Note that hardware does not clear the BA bits (including BA4) when switching from IDE mode to non-IDE mode or vice versa. BIOS is responsible for clearing those bits to 0 since the number of writable bits changes after mode switching.

### Access Method

**Type:** PCI Configuration Register (Size: 32 bits)

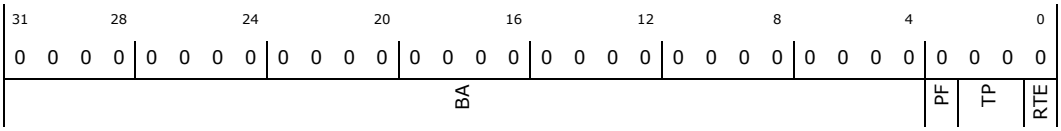
**LBAR:** [B:0, D:19, F:0] + 20h

**Default:** 00000001h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31:16 | 0b<br>RO | **RSVD0:** Reserved |

| Bit Range | Default & Access | Description |
|---|---|---|
| 15:4 | 0h<br>RW | **Base Address (BA):** Base address of the I/O space. Note for Base Address bit 4: When CC.SCC is 01h, this bit will be RW resulting in requesting 16B of I/O space. When CC.SCC is not 01h, this bit will be RO=0 resulting in requesting 32B of I/O space. |
| 3:1 | 0b<br>RO | **RSVD1:** Reserved |
| 0 | 1h<br>RO | **Resource Type Indicator (RTE):** Indicates a request for IO space. |

## 17.5.15 AHCI Base Address/Serial ATA Index Data Pair Base Address (ABAR)—Offset 24h



When the programming interface is not IDE (i.e. CC.SCC is not 01h), this register is named ABAR. When the programming interface is IDE, this register becomes SIDPBA. Note that hardware does not clear those BA bits when switching from IDE SKU to non-IDE SKU or vice versa. BIOS is responsible for clearing those bits to 0 since the number of writable bits changes after SKU switching (as indicated by a change in CC.SCC). In the case, this register will then have to be re-programmed to a proper value. When the programming interface is not IDE, the register represents a memory BAR allocating space for the AHCI memory registers. Note that bit[31:16] of this register must be programmed to a value greater than 0 to ensure the memory is mapped to an address of 1 MBytes and greater (i.e. ABAR must be 00010000h or greater). Otherwise, memory cycle targeting the ABAR range may not be accepted. When the programming interface is IDE, the register becomes an I/O BAR allocating 16 bytes of I/O space for the I/O mapped registers defined in Memory Registers. Note that although 16 bytes of locations are allocated, only 8 bytes are used as SINDX and SDATA registers; with the remaining 8 bytes preserved for future enhancement.

### Access Method

**Type:** PCI Configuration Register (Size: 32 bits)

**ABAR:** [B:0, D:19, F:0] + 24h

**Default:** 00000000h

| Bit Range | Default & Access | Description |

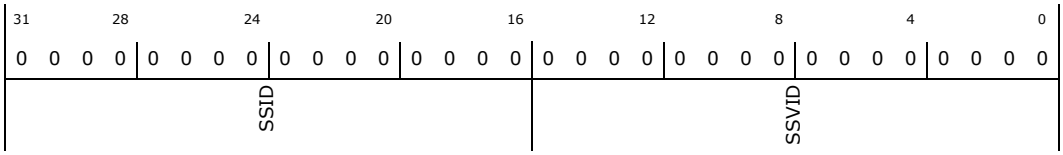
Bits 31:11 are RW, bits 10:4 are RO of 0; When programming interface is IDE, this is base address of the I/O space. Bits 31:16 are RO of 0, bits 15:4 are RW |
| 3 | 0h<br>RO | **Prefetchable (PF):** When programming interface is non IDE, this indicates that this range is not prefetch-able |
| 2:1 | 0h<br>RO | **Type (TP):** When programming interface is non IDE, this indicates that this range can be mapped anywhere in 32-bit address space |
| 0 | 0h<br>RO | **Resource Type Indicator (RTE):** When programming interface is non IDE, this indicates a request for register memory space; When programming interface is IDE, this indicates a request for IO space. |

## 17.5.16 Sub System Identifiers (SS)—Offset 2Ch



This register is initialized to logic 0 by the assertion of Backbone Reset. This register can be written only once after Backbone Reset de-assertion.

### Access Method

**Type:** PCI Configuration Register (Size: 32 bits)

**SS:** [B:0, D:19, F:0] + 2Ch

**Default:** 00000000h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31:16 | 0000h RW/O | **Subsystem ID (SSID):** This is written by BIOS. No hardware action taken on this value. |

## 17.5.17 Capabilities Pointer (CAP)—Offset 34h

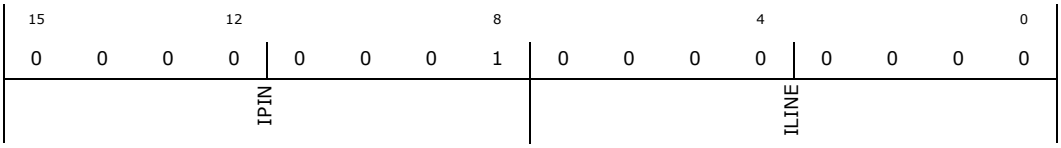
### Access Method

**Type:** PCI Configuration Register (Size: 8 bits)

**CAP:** [B:0, D:19, F:0] + 34h

**Default:** 80h

| Bit Range | Default & Access | Description |
|---|---|---|
| 7:0 | 80h RW/L | **Capability Pointer (CP):** Indicates that the first capability pointer offset is offset 80h (the Message Signaled Interrupt capability). The following capability structures are linked by default which is meant for non-IDE mode: CAP.CP - 80h (MSI) - 70h (PCI Power) - A8h (SATA) - 00h end. BIOS may alter the capability structure list above (by programming a leading capability structure's Next Pointer field) if BIOS wants to bypass any specific capability.[Br] If BIOS intends to operate in IDE mode, BIOS is requested to program this field to 70h and the subsequent capability list as such: CAP.CP - 70h (PCI Power) - end. The RW/L register attribute allows for flexibility in determining the capability structure available in this PCI function. Refer to SATAGC.REGLOCK description in order to lock the register to become RO. |



## 17.5.18 Interrupt Information (INTR)—Offset 3Ch

### Access Method

**Type:** PCI Configuration Register (Size: 16 bits)

**INTR:** [B:0, D:19, F:0] + 3Ch

**Default:** 0100h

| Bit Range | Default & Access | Description |
|---|---|---|
| 15:8 | 01h<br>RO | **Interrupt Pin (IPIN):** This register tells which interrupt pin the device function uses. A value of 1 corresponds to INTA#. A value of 2 corresponds to INTB#. A value of 3 corresponds to INTC#. A value of 4 corresponds to INTD#. |
| 7:0 | 00h<br>RW | **Interrupt Line (ILINE):** Software written value to indicate which interrupt line (vector) the interrupt is connected to. No hardware action is taken on this register. |

## 17.5.19 Minimum Grant (MGNT)—Offset 3Eh

### Access Method

**Type:** PCI Configuration Register (Size: 8 bits)

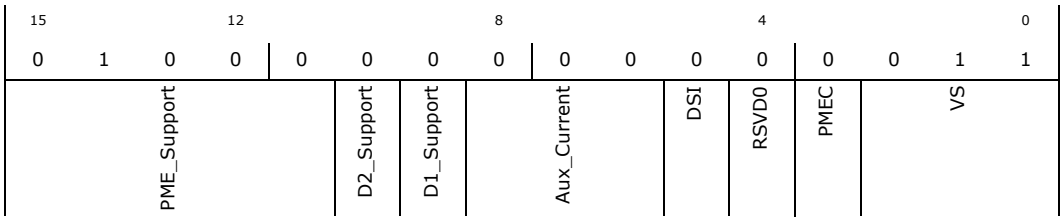
**Default:** A801h

| Bit Range | Default & Access | Description |
|---|---|---|
| 15:8 | A8h<br>RW/L | **Next Capability (NEXT):** A8h is location of the Serial ATA Capability structure. This is recommended for non-IDE mode. If the controller is to operate in IDE mode, BIOS is requested to program this field to 00h indicating the end (recommended setting). The RW/L register attribute allows for flexibility in determining the capability structure available in this PCI function. Refer to SATAGC.REGLOCK description in order to lock the register to become RO. |
| 7:0 | 01h<br>RO | **Cap ID (CID):** Indicates that this pointer is a PCI power management capability. |



## 17.5.28 PCI Power Management Capabilities (PC)—Offset 72h

### Access Method

**Type:** PCI Configuration Register (Size: 16 bits)

**PC:** [B:0, D:19, F:0] + 72h

**Default:** 4003h

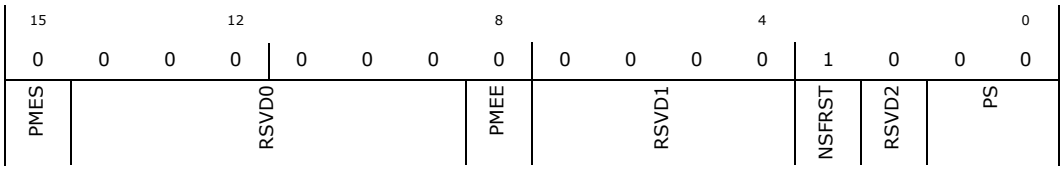
|---|---|---|
| 15:11 | 08h RO | **PME_Support:** By default with CC.SCC=01h, the default value is 00000 which indicates no PME Support in IDE mode. When CC.SCC is not 01h in non-IDE mode, the default value is 01000 which indicates PME# can be generated from the D3HOT state in the SATA controller. |
| 10 | 0h RO | **D2_Support:** The D2 state is not supported. |
| 9 | 0h RO | **D1_Support:** The D1 state is not supported. |
| 8:6 | 0h RO | **Aux_Current:** PME# from D3COLD state is not supported, therefore this field is 000b. |
| 5 | 0h RO | **Device Specific Initialization (DSI):** Indicates that no device-specific initialization is required. |
| 4 | 0b RO | **RSVD0:** Reserved |
| 3 | 0h RO | **PME Clock (PMEC):** Indicates that PCI clock is not required to generate PME#. |
| 2:0 | 3h RO | **Version (VS):** Indicates support for Revision 1.2 of the PCI Power Management Specification. |



## 17.5.29 PCI Power Management Control and Status (PMCS)—Offset 74h

### Access Method

**Type:** PCI Configuration Register (Size: 16 bits)

**PMCS:** [B:0, D:19, F:0] + 74h

**Default:** 0008h

| Bit Range | Default & Access | Description |
|---|---|---|
| 15 | 0h RW | **PME Status (PMES):** This bit is set when a PME event is to be requested, and if this bit is set and PMEE is set, a PME# will be generated. -Note: Whenever CC.SCC=01h either by default or just being updated, hardware shall automatically change the attribute to RO of 0. |
| 14:9 | 0b RO | **RSVD0:** Reserved |

| Bit Range | Default & Access | Description |
|---|---|---|
| 8 | 0h<br>RW | **PME Enable (PMEE):** When CC.SCC is not 01h, this bit is RW. When set, the SATA controller generates PME# from D3HOT on a wake event. Whenever CC.SCC=01h either by default or just being updated, hardware shall automatically change the attribute to RO of 0 since there is no PME Support in IDE mode. Note: Software is advised to clear PMEE together with PMES prior to changing CC.SCC thru MAP.SMS. |

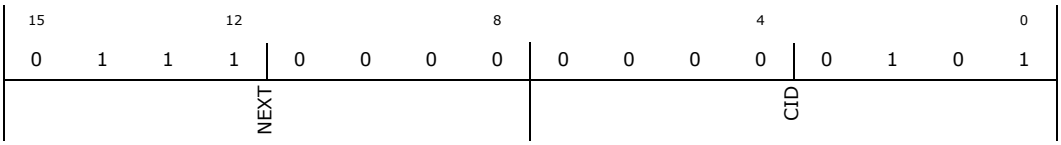
| 3 | 1h<br>RO | **No Soft Reset (NSFRST):** A 1 indicates that devices transitioning from D3hot to D0 because of Power_State commands do not perform an internal reset. Configuration context is preserved. Upon transition from the D3hot to the D0 initialized state, no additional operating system intervention is required to preserve configuration context beyond writing to the Power_State bits. Regardless of this bit, the controller transition from D3hot to the D0 by a system or bus segment reset will return to the state D0 uninitialized with only PME context preserved if PME is supported and enabled. |
| 2 | 0b<br>RO | **RSVD2:** Reserved |
| 1:0 | 0h<br>RW | **Power State (PS):** This field is used both to determine the current power state of the SATA Controller and to set a new power state. The values are: 00 = D0 state; 11 = D3HOT state. When in the D3HOT state, the controller's configuration space is available, but the I/O and memory spaces are not. Additionally, interrupts are blocked. If software attempts to write a 10 or 01 to these bits, the write will be ignored. Refer to PCI PM specification section 8.2.2. on software requirements in ensuring I/O space, memory space and Bus Master are disabled prior to entering D3 state. |



## 17.5.30 Message Signaled Interrupt Identifier (MID)—Offset 80h

### Access Method

**Type:** PCI Configuration Register (Size: 16 bits)

**MID:** [B:0, D:19, F:0] + 80h

**Default:** 7005h

| Bit Range | Default & Access | Description |
|---|---|---|
| 15:8 | 70h<br>RW/L | **Next Pointer (NEXT):** Indicates the next item in the list is the PCI power management pointer. This is the recommended value. BIOS may program this field to A8h indicating that the next item is Serial ATA Capability structure. The RW/L register attribute allows for flexibility in determining the capability structure available in this PCI function. Refer to SATAGC.REGLOCK description in order to lock the register to become RO. |

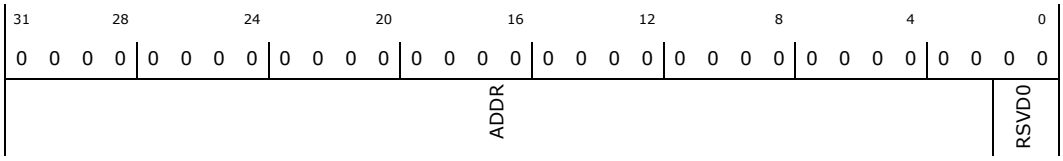
Software must clear this bit to 0 to disable MSI first before changing the number of messages allocated in the MMC field. Software must also make sure this bit is cleared to 0 when operating in legacy mode (for AHCI SKUs when GHC.AE = 0). This bit is RW when CC.SCC is not 01h and is read-only 0 when CC.SCC is 01h. |



## 17.5.32 Message Signaled Interrupt Message Address (MA)—Offset 84h

### Access Method

**Type:** PCI Configuration Register (Size: 32 bits)

**MA:** [B:0, D:19, F:0] + 84h

**Default:** 00000000h

## 17.5.33 Message Signaled Interrupt Message Data (MD)—Offset 88h

### Access Method

**Type:** PCI Configuration Register (Size: 16 bits)

**MD:** [B:0, D:19, F:0] + 88h

**Default:** 0000h

| Bit Range | Default & Access | Description |
|---|---|---|

## 17.5.34 Port Mapping Register (MAP)—Offset 90h

### Access Method

**Type:** PCI Configuration Register (Size: 16 bits)

**MAP:** [B:0, D:19, F:0] + 90h

**Default:** 0420h

| Bit Range | Default & Access | Description |

| 11:10 | 1h<br>RO | **SATA Port Disable (SPD0):** A 1 in a bit position corresponding to the SATA port prevents the SATA port from being enabled via config PCS.PxE. Write of 1 to PCS.PxE has no effect when the corresponding SPD[x] bit is 1. In preventing a port(s) from being enabled, BIOS shall first configure MAP.SPD. And only then BIOS configures the PCS.PxE. |
| 9:8 | 0h<br>RO | **SATA Port Disable (SPD):** A 1 in a bit position corresponding to the SATA port prevents the SATA port from being enabled via config PCS.PxE. Write of 1 to PCS.PxE has no effect when the corresponding SPD[x] bit is 1. In preventing a port(s) from being enabled, BIOS shall first configure MAP.SPD. And only then BIOS configures the PCS.PxE. |
| 7:6 | 0h<br>RW | **SATA Mode Select (SMS):** Software (SW) programs these bits to control the mode in which the SATA HBA should operate: 00b = IDE mode which requires LBC01.LBGE=1 (refer to LBC01, LBC23 and LBC45 register in SIR register space); 01b = AHCI mode; 10b = RAID mode; 11b = Reserved. Notes : SW shall not manipulate MAP.SMS during runtime operation; i.e. the OS will not do this. The BIOS may choose to switch from one mode to another during POST. IDE mode can be selected when AHCI and/or RAID are enabled. After switching from AHCI/RAID back to IDE mode, the number of usable ports on SATA Controller 1 shall be reduced to 4, dependent on SKUs. AHCI mode may only be selected when MV = 00b. AHCI mode may be selected when RAID feature is enabled by fuse. VLV does not support RAID mode. Programming these bits with values that are illegal will result in in-deterministic behavior by the HW. |

| Bit Range | Default & Access | Description |
|---|---|---|
| 5 | 1h<br>RW | **SATA Port-to-Controller Configuration (SC):** This bit changes number of SATA port availability within each SATA controller. When MAP.SPD[5] is 1 and MAP.SPD[4] is 1, this bit is reserved and is read-only 1 else it's RW-zero. When this bit is 0: Up to 2 SATA ports are available in the SATA controller 1 with port[1:0]. When this bit to 1: Up to 2 SATA ports are available in the SATA controller 1 with port [1:0]. For SMS=IDE mode, this bit should be 0 (note that this irrespective of the number of SATA ports). The number of port availability in this controller shall be discoverable thru this controller's config PCS.PxE, AHCI CAP.NP and AHCI PI[x] register fields. Prior to changing the state of this bit, all ports must be in quiescent state with no commands outstanding. Refer to Single and Dual Controller Switching Requirement for additional software and hardware requirements. |

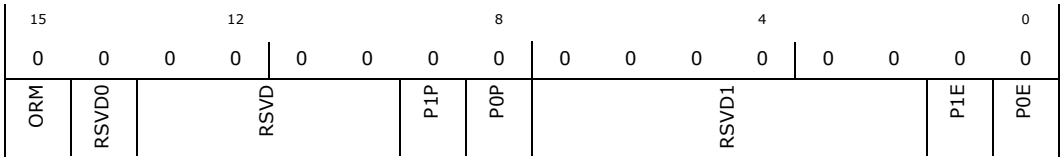
| 1:0 | 0h<br>RO | **Map Value (MV):** This register is reserved. |

## 17.5.35 Port Control and Status (PCS)—Offset 92h



By default, the SATA ports are set (by hardware) to the disabled state (e.g. bits[5:0] == 0) as a result of an initial power on reset. When enabled by software, the ports can transition between the on, partial, and slumber states and can detect devices. When disabled, the port is in the off state and cannot detect any devices. Note: AHCI specific notes: If an AHCI-aware or RAID enabled operating system is being booted then system BIOS shall insure that all supported SATA ports are enabled prior to passing control to the OS. Once the AHCI aware OS is booted it becomes the enabling/disabling policy owner for the individual SATA ports. This is accomplished by manipulating a port's PxSCTL.DET and PxCMD.SUD fields. Because an AHCI or RAID aware OS will typically not have knowledge of the PxE bits and because the PxE bits act as master on/off switches for the ports, pre-boot software must insure that these bits are set to 1 prior to booting the OS, regardless as to whether or not a device is currently on the port.

### Access Method

**Type:** PCI Configuration Register (Size: 16 bits)

**Default:** 0000h

| Bit Range | Default & Access | Description |
|---|---|---|
| 15 | 0h<br>RW | **OOB Retry Mode (ORM):** When cleared, the SATA controller will not retry after an OOB failure. When set, the SATA controller will continue to retry after an OOB failure until successful (infinite retry). BIOS is requested to program this field to 1. |

| 9 | 0h<br>RO | **Port 1 Present (P1P):** Same as P0P, except for port 1. |

| Bit Range | Default & Access | Description |
|---|---|---|
| 8 | 0h<br>RO | **Port 0 Present (P0P):** When set, the SATA controller has detected the presence of a device on port 0. It may change at any time. Clearing P0E bit leads to clearing of this bit after implementation delay. Note: For system software that intends to clear all PCS.PxE bits that are previously 1 to 0 and then to 1 again in two consecutive write cycles, software shall poll on this bit being 0 before setting P0E bit to 1. |

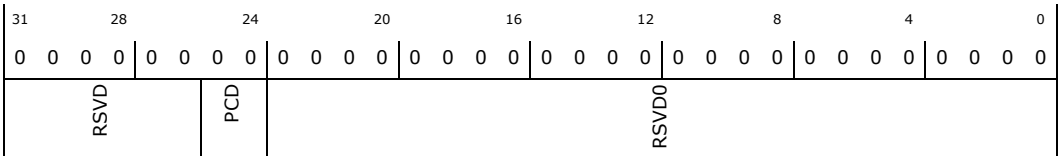
| 1 | 0h<br>RW | **Port 1 Enabled (P1E):** When MAP.SPD[1] is 1, this bit is reserved and read-only 0. Otherwise if none of the above is true, this bit is RW and same as P0E but for port 1 and takes precedence over P1CMD.SUD. |
| 0 | 0h<br>RW | **Port 0 Enabled (P0E):** When MAP.SPD[0] is 1, this bit is reserved and read-only 0. When set, the port is enabled. When cleared, the port is disabled. When enabled, the port can transition between the on, partial, and slumber states and can detect devices. When disabled, the port is in the off state and cannot detect any devices. This bit takes precedence over P0CMD.SUD. Note: The recommendation for software code that intends to clear all PCS.PxE bits that are previously 1 to 0 and then to 1 again immediately shall refer to the polling requirement as described in P0P register bit. At any time that BIOS or software is clearing PCS.PxE from 1 to 0, due to time needed for port staggering hardware process (up to 2 ports) to complete, BIOS and software shall delay the write to set the TM.PCD register by 1.4us. |



## 17.5.36 Test Mode Register (TM)—Offset 94h

### Access Method

**Type:** PCI Configuration Register (Size: 32 bits)

**TM:** [B:0, D:19, F:0] + 94h

**Default:** 00000000h

| Bit Range | Default & Access | Description |

## 17.5.37 SATA General Configuration (SATAGC)—Offset 9Ch

### Access Method

**Type:** PCI Configuration Register (Size: 32 bits)

**SATAGC:** [B:0, D:19, F:0] + 9Ch

**Default:** 00000000h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31 | 0h<br>RW/O | **Register Lock (REGLOCK):** BIOS can set this bit to 1 to lock the following registers with RW/L attribute: CAP,CP, MID.NEXT, PIE.NEXT, SATACR0.NEXT. Once locked the register attribute of above list changes from RW/L to RO holding the existing value. BIOS is requested to program this field to 1 prior to handle off to OS. If BIOS needs the SATA host controller to change operation a few times (i.e. changing CC.SCC mode) and need different capability structures for each specific operation mode, BIOS need not activate the lock until BIOS is ready to hand off to OS. BIOS may need to separate write access to this byte offset (x9Fh) from write to the lower 3-byte of the dword (x9C-9Eh) if there is a need to program the lower 3-byte dword location early during boot process. |
| 30:15 | 0b<br>RO | **RSVD0:** Reserved |
| 14:12 | 0h<br>RW | **Write Request_Size Select/Max_Payload_Size (WRRSELMPS):** These two bits select the max write request size that SATA host controller will initiate for DMA write to memory. SATA host controller will internally break up larger write request based on these bits. The request is address-aligned to the selected size. Defined encodings for this field are: 000b = 128 address aligned bytes max payload size; 111b = 64 address aligned bytes max payload size. All other values are reserved for SATA host controller. |
| 11:10 | 0b<br>RO | **RSVD1:** Reserved |
| 9 | 0h<br>RW | **Unsupported Request Reporting Enable (URRE):** If set to 1 by software, it allows reporting of an Unsupported Request as a system error. If both URRE and PCI configuration SERR# Enable registers are set to a 1, then the agent must set the Signaled System Error bit in the PCI Status register and send a DO_SERR message in IOSF-SB interface. |
| 8 | 0h<br>RW/1C | **Unsupported Request Detected (URD):** Set to 1 by hardware upon detecting an Unsupported Request on IOSF Primary interface that is not considered Advisory Non-Fatal. Cleared to 0 by SW. |
| 7 | 0h<br>RW/O | **Alternate ID Enable (AIE):** When programmed to 0, HW will report the following device id's: 2822h for desktop or 282Ah for mobile. When programmed to a 1, HW will not report these device id's. The value is product specific. Note: Programming this bit to a 1 will prevent the Windows in-box version of the Intel AHCI driver from loading on the platform - will require that the user perform an 'F6' install of the Intel driver that is appropriate for the reported DID. This field is applicable when the AHCI is configured for RAID mode of operation. It has no impact for AHCI and IDE modes of operation. Note: BIOS is recommended to program this bit prior to programming the MAP.SMS field to reflect RAID. This field is reset by Backbone Reset and BIOS is required to reprogram the value (either 0 or 1) after resuming from S3, S4 or S5. This insures that the value is properly and cannot be changed during runtime. |
| 6 | 0h<br>RW/O | **AIE0 DevID Selection (DEVIDSEL):** This register allows BIOS to select Device ID when AIE=0 and Server Feature Disable Fuse 7 =0. This bit only has effect in Desktop SKU. In Mobile SKU this bit has no effect at all. Refer to config register offset 09h PI for usage. 0 : 2822h; 1 : 2826h. NOTE: When Server Feature (SATA AIE DEVIDSEL) Disable Fuse 7 is programmed to 1, this disables the writeability of this DEVIDSEL register bit, and becomes RO with a value of 0, which only allows a choice of 2822h. |
| 5 | 0h<br>RW/O | **FLR Capability Selection (FLRCSSEL):** This allows the FLR Capability to be bypassed. Refer to config offset B0h. BIOS is requested to program this bit to 1 and config offset A8h SATACR0.NEXT to 00h. |

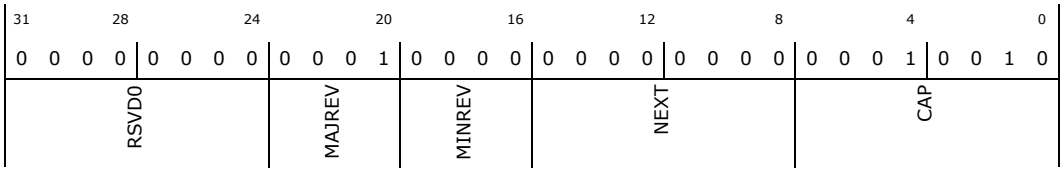
## 17.5.40 Serial ATA Capability Register 0 (SATACR0)—Offset A8h



This register shall be read-only 0 when CC.SCC is 01h. Note that the SATACR0.NEXT is not changed from RO to become RWO because there is an existing method (SATAGC.FLRCSSEL bit) to bypass the FLR Capability structure. And FLR Capability ID.NEXT is already indicating end of capability structure, it does not need change to be RWO.

### Access Method

**Type:** PCI Configuration Register (Size: 32 bits)

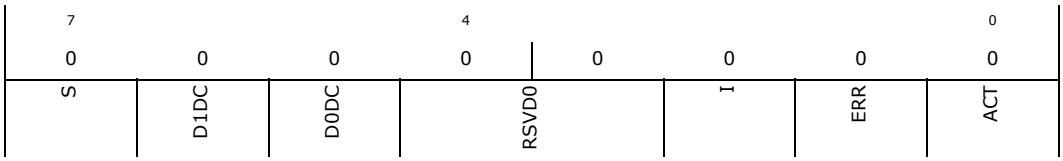
| 0 | 0h<br>RW | **Start/Stop Bus Master (START):** Setting this bit enables bus master operation of the controller. Bus master operation does not actually start unless the Bus Master Enable bit in PCI configuration space is also set. Clearing it halts bus master operation. All state information is lost when this bit is written to 0; Master mode operation cannot be stopped and then resumed. If this bit is reset while bus master operation is still active and the device has not yet finished its data transfer, the bus master command is said to be aborted. If this bit is cleared to 0 prior to the DMA data transfer being initiated by the drive in a device to memory data transfer, then not DMAT will be sent to terminate the data transfer. SW intervention (e.g. sending SRST) is required to reset the interface in this condition. This bit is intended to be cleared by software after the data transfer is completed - as indicated by either the ACT bit being cleared in the status register, or the I bit being set in the status register, or both. |

## 17.6.2 Primary Status (PSTS)—Offset 2h



### Access Method

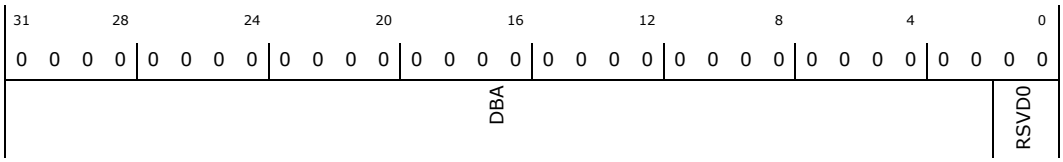
**Default:** 00h

| Bit Range | Default & Access | Description |
|---|---|---|
| 7 | 0h<br>RO | **Simplex Only (S):** This read-only bit indicates whether or not I both bus master channels (primary and secondary) can be operated at the same time. If the bit is a 0, then the channels operate independently and can be used at the same time. If the bit is a 1, then only one channel may be used at a time. |
| 6 | 0h<br>RW | **Device 1 DMA Capable (D1DC):** A scratchpad bit set by SW to indicate that device 1 of this channel is capable of DMA transfers. This bit has no effect on the hardware. |
| 5 | 0h<br>RW | **Device 0 DMA Capable (D0DC):** A scratchpad bit set by SW to indicate that device 0 of this channel is capable of DMA transfers. This bit has no effect on the hardware. |
| 4:3 | 0b<br>RO | **RSVD0:** Reserved |
| 2 | 0h<br>RW/1C | **Interrupt (I):** This bit is set when a device FIS is received with the I bit has been set provided that software has not disabled interrupt via the nIEN bit of Device Control Register. |
| 1 | 0h<br>RW/1C | **Error (ERR):** This bit is set when the controller encounters an error during the transfer and must stop the transfer. See Error Handling for the list of errors that set this bit. |
| 0 | 0h<br>RO | **Active (ACT):** Set by the host when the START bit is written to the Command register, and cleared by the host when the last transfer for a region is performed, where EOT for that region is set in the region descriptor, and when the START bit is cleared in the Command register and the controller has returned to an idle condition. |

## 17.6.3 Primary Descriptor Table Pointer (PDTP)—Offset 4h



### Access Method

**Type:** I/O Register
(Size: 32 bits)

**PDTP:** [LBAR] + 4h

**LBAR Type:** PCI Configuration Register (Size: 32 bits)
**LBAR Reference:** [B:0, D:19, F:0] + 20h

**Default:** 00000000h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31:2 | 00000000h<br>RW | **Descriptor Base Address (DBA):** Corresponds to A[31:2]. This table must not cross a 64K boundary in memory. When read, the current value of the pointer is returned |

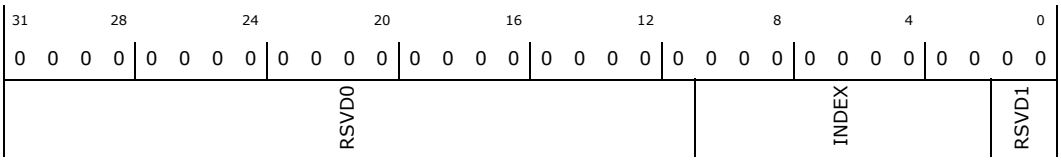
## 17.6.7 AHCI Index Register (INDEX)—Offset 10h

This registers are only available if CC.SCC is not 01h to index into all memory registers defined in Memory Registers and the message buffer used for enclosure management. If CC.SCC is 01h, these AHCI Index Data Pair registers are not accessible and SINDEX/SDATA register pair shall be used to index into a subset of the memory registers defined in (See Memory Registers for more information on which registers could be indexed).



### Access Method

**Type:** I/O Register (Size: 32 bits)

**INDEX:** [LBAR] + 10h

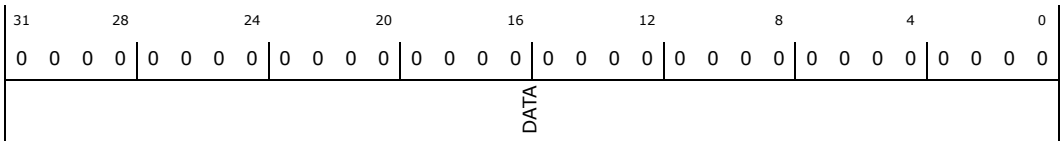
**LBAR Type:** PCI Configuration Register (Size: 32 bits)
**LBAR Reference:** [B:0, D:19, F:0] + 20h

**Default:** 00000000h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31:11 | 0b<br>RO | **RSVD0:** Reserved |
| 10:2 | 000h<br>RO | **Index (INDEX):** This Index register is used to select the Dword offset of the Memory Mapped AHCI register to be accessed. A Dword, Word or Byte access is specified by the active byte enables of the I/O access to the Data register. |
| 1:0 | 0b<br>RO | **RSVD1:** Reserved |

## 17.6.8 AHCI Data Register (DATA)—Offset 14h

This registers are only available if CC.SCC is not 01h to index into all memory registers defined in Memory Registers and the message buffer used for enclosure management. If CC.SCC is 01h, these AHCI Index Data Pair registers are not accessible and SINDEX/SDATA register pair shall be used to index into a subset of the memory registers defined in (See Memory Registers for more information on which registers could be indexed).



### Access Method

**Type:** I/O Register (Size: 32 bits)

**DATA:** [LBAR] + 14h

**LBAR Type:** PCI Configuration Register (Size: 32 bits)
**LBAR Reference:** [B:0, D:19, F:0] + 20h

**Default:** 00000000h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31:0 | 00000000h RW | **Data (DATA):** This Data register is a window through which data is read or written to the memory mapped register pointed to by the Index register. Note that a physical register is not actually implemented as the data is actually stored in the memory mapped registers. Since this is not a physical register, the default value is the same as the default value of the register pointed to by Index. |

## 17.7 SATA Index Pair IO Registers

### Table 195. Summary of SATA Index Pair I/O Registers—ABAR

| Offset | Size | Register ID—Description | Default Value |
|---|---|---|---|
| 0h | 4 | "Serial ATA Index (SINDX)—Offset 0h" on page 1967 | 00000000h |
| 4h | 4 | "Serial ATA Data (SDATA)—Offset 4h" on page 1968 | 00000000h |

## 17.7.1 Serial ATA Index (SINDX)—Offset 0h

All of these I/O registers are in the core well. They are exposed only when CC.SCC is 01h (i.e. IDE programming interface). These are Index/Data Pair registers that are used to access the SerialATA superset registers (SerialATA Status, SerialATA Control and SerialATA Error). The I/O space for these registers is allocated through SIDPBA. Locations with offset from 08h to 0Fh are reserved for future expansion. Software write operations to the reserved locations shall have no effect while software read operations to the reserved locations shall return 0. Refer to Serial ATA Index/Data Pair Superset Registers for more details.

| 15:8 | 00h<br>RW | **Port Index (PIDX):** This index field is used to specify the port of the SATA controller that the port specific SerialATA Status (SSTS), SerialATA Control (SCTL) and SerialATA Error (SERR) registers are to be read from or write to. 00h = Primary Master (Port 0); 01h = Primary Slave (Port 2); 02h = Secondary Master (Port 1); 03h = Secondary Slave (Port 3). |
| 7:0 | 00h<br>RW | **Register Index (RIDX):** This index field is used to specify one out of three registers currently being indexed into. These three registers are the Serial ATA superset SStatus, SControl and SError memory registers and are port specific, hence for this SATA controller, there are four sets of these registers. Refer to Offset 128h, 1A8h, 228h, 2A8h, 328h, 3A8h: PxSSTS - Port [0-5] Serial ATA Status, Offset 12Ch, 1ACh, 22Ch, 2ACh, 32Ch, 3ACh: PxSCTL - Port [0-5] Serial ATA Control, and Offset 130h, 1B0h, 230h, 2B0h, 330h, 3B0h: PxSERR - Port [0-5] Serial ATA Error for definitions of the SStatus, SControl and SError registers. 00h = SSTS; 01h = SCTL; 02h = SERR. |

## 17.7.2 Serial ATA Data (SDATA)—Offset 4h

All of these I/O registers are in the core well. They are exposed only when CC.SCC is 01h (i.e. IDE programming interface). These are Index/Data Pair registers that are used to access the SerialATA superset registers (SerialATA Status, SerialATA Control and SerialATA Error). The I/O space for these registers is allocated through SIDPBA. Locations with offset from 08h to 0Fh are reserved for future expansion. ## 17.8.1 HBA Capabilities (GHC_CAP)—Offset 0h

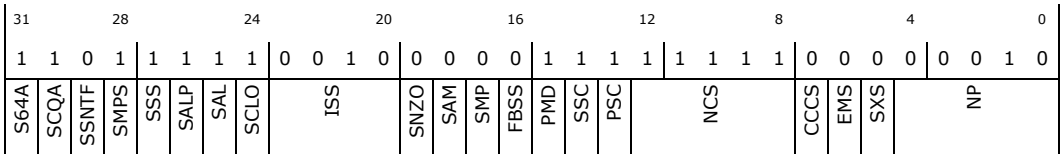
This register indicates basic capabilities of the HBA to driver software. The RWO bits in this register are only cleared upon Backbone Reset.



### Access Method

**Type:** Memory Mapped I/O Register (Size: 32 bits)

**GHC_CAP:** [ABAR] + 0h

**ABAR Type:** PCI Configuration Register (Size: 32 bits)
**ABAR Reference:** [B:0, D:19, F:0] + 24h

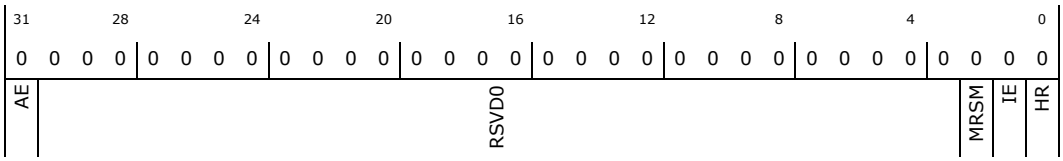
**Default:** DF20FF02h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31 | 1h RW/O | **Supports 64-bit Addressing (S64A):** Indicates the S-ATA controller can access 64-bit data structures. The 32-bit upper bits of the port DMA Descriptor, the PRD Base, and each PRD entry are read/write. |
| 30 | 1h RW/O | **Supports Native Command Queuing Acceleration (SCQA):** Indicates the SATA controller supports Serial-ATA Native Command Queuing. The HBA will handle DMA Setup FISes in hardware, including support for auto-activate optimization through the FIS. |
| 29 | 0h RO | **Supports SNotification Register (SSNTF):** When set to 1, indicates that the HBA supports the PxSNTF (SNotification) register and its associated functionality. When cleared to 0, the HBA does not support the PxSNTF (SNotification) register and its associated functionality. |
| 28 | 1h RW/O | **Supports Mechanical Presence Switch (SMPS):** When set to 1, the HBA supports mechanical presence switches on its ports for use in hot plug operations. When cleared to 0, this function is not supported. This value is loaded by the BIOS prior to OS initialization. |
| 27 | 1h RW/O | **Supports Staggered Spin-up (SSS):** Indicates whether the S-ATA controller supports staggered spin-up on its ports, for use in balancing power spikes. This value is loaded by platform BIOS prior to OS initialization. |
| 26 | 1h RW/O | **Supports Aggressive Link Power Management (SALP):** Indicates the S-ATA controller supports auto-generating link requests to the partial or slumber states when there are no commands to process. When cleared to 0, software shall treat the PxCMD.ALPE and PxCMD.ASP bits as reserved. |

| Bit Range | Default & Access | Description |
|---|---|---|
| 25 | 1h RW/O | **Supports Activity LED (SAL):** Indicates the S-ATA controller supports a single output pin (SATALED#) which indicates activity. |
| 24 | 1h RW/O | **Supports Command List Override (SCLO):** When set to 1, indicates that the HBA supports the PxCMD.CLO bit and its associated function. When cleared to 0, The HBA is not capable of clearing the BSY and DRQ bits in the Status register in order to issue software reset if these bits are still set from a previous operation. |
| 23:20 | 2h RW/O | **Interface Speed Support (ISS):** Indicates the maximum speed the S-ATA controller can support on its ports. These encodings match the system software programmable PxSCTL.DET.SPD field. 0000 = Reserved; 0001 = Gen 1 (1.5 Gbps); 0010 = Gen 2 (3 Gbps); 0011 = Gen 3 (6 Gbps); 0100 - 1111 = Reserved. |
| 19 | 0h RO | **Supports Non-Zero DMA Offsets (SNZO):** Reserved as per AHCI 1.3 |
| 18 | 0h RW/O | **Supports AHCI mode only (SAM):** The SATA controller may optionally support AHCI access mechanism only. A value of 0 indicates that in addition to the native AHCI mechanism (via ABAR), the SATA controller implements a legacy, task-file based register interface such as SFF-8038i. A value of 1 indicates that the SATA controller does not implement a legacy, task-file based register interface. |
| 17 | 0h RO | **Supports Port Multiplier (SMP):** Not supported. |
| 16 | 0h RO | **FIS-based Switching Supported (FBSS):** Not supported. |
| 15 | 1h RO | **PIO Multiple DRQ Block (PMD):** If set to 1, the HBA supports multiple DRQ block data transfers for the PIO command protocol. |
| 14 | 1h RW/O | **Slumber State Capable (SSC):** The SATA controller supports the slumber state. |
| 13 | 1h RW/O | **Partial State Capable (PSC):** The SATA controller supports the partial state. |
| 12:8 | 1Fh RO | **Number of Command Slots (NCS):** 1Fh indicating support for 32 slots. |
| 7 | 0h RO | **Command Completion Coalescing Supported (CCCS):** When set to 1, indicates that the HBA supports command completion coalescing. When command completion coalescing is supported, the HBA has implemented the CCC_CTL and the CCC_PORTS global HBA registers. When cleared to 0, indicates that the HBA does not support command completion coalescing and the CCC_CTL and CCC_PORTS global HBA registers are not implemented. |
| 6 | 0h RO | **Enclosure Management Supported (EMS):** Not supported |
| 5 | 0h RW/O | **Supports External SATA (SXS):** When set to 1, indicates that the HBA has one or more Serial ATA ports that has a signal only connector that is externally accessible. If this bit is set, software may refer to the PxCMD.ESP bit to determine whether a specific port has its signal connector externally accessible as a signal only connector (i.e. power is not part of that connector). When the bit is cleared to 0, indicates that the HBA has no Serial ATA ports that have a signal only connector externally accessible. |
| 4:0 | 02h RO | **Number of Ports (NP):** 0's based value indicating the maximum number of ports supported. Note that the number of ports indicated in this field may be more than the number of ports indicated in the PI register. Number of ports shall be dependent on MAP.SC and PCIe/SATA muxing configuration where if ANY of these parameter disable a particular port then that port is disabled and not counted. The maximum number of ports supported by SIP is 2 and the least is 0 (i.e. Function Disable). In the case of 0 port configuration, the value of NP is a don't care (while implementation has it fixed as 07h). Any combination in between is supported by SATA host controller. Indicates the number of supported ports. |

## 17.8.2 Global HBA Control (GHC)—Offset 4h

This register controls various global actions of the HBA.



### Access Method

**Type:** Memory Mapped I/O Register (Size: 32 bits)

**GHC:** [ABAR] + 4h

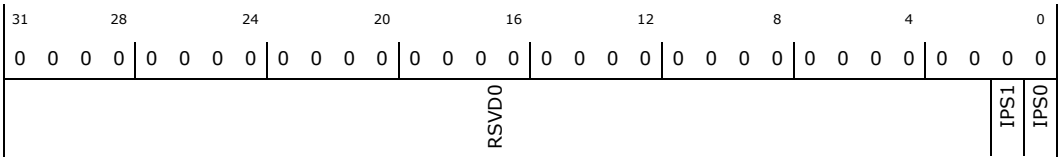
**ABAR Type:** PCI Configuration Register (Size: 32 bits)
**ABAR Reference:** [B:0, D:19, F:0] + 24h

**Default:** 00000000h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31 | 0h<br>RW | **AHCI Enable (AE):** When set, indicates that an AHCI driver is loaded and communication to the HBA shall be via AHCI mechanisms. This can be used by an HBA that supports both legacy mechanisms (such as SFF-8038i) and AHCI to know when the HBA is running under an AHCI driver. When set, software shall only talk to the HBA using AHCI. The HBA will not have to allow command processing via both AHCI and legacy mechanisms. When cleared, software will only communicate with the HBA using legacy mechanisms. Software shall set this bit to 1 before accessing other AHCI registers. Note: The implementation of this bit is dependent upon the value of the CAP.SAM bit. If CAP.SAM is 0, then GHC.AE should be RW and shall have a reset value of 0. If CAP.SAM is 1, then AE shall be read only and shall have a reset value of 1. |
| 30:3 | 0b<br>RO | **RSVD0:** Reserved |
| 2 | 0h<br>RO | **MSI Revert to Single Message (MRSM):** When set to 1 by hardware, indicates that the HBA requested more than one MSI vector but has reverted to using the first vector only. When this bit is cleared to 0, the HBA has not reverted to single MSI mode (i.e. hardware is already in single MSI mode, software has allocated the number of messages requested, or hardware is sharing interrupt vectors if MC.MME ( MC.MMC). The HBA may revert to single MSI mode when the number of vectors allocated by the host is less than the number requested. This bit shall only be set to 1 when the following conditions hold: MC.MSIE = 1 (MSI is enabled); MC.MMC ) 0 (multiple messages requested); MC.MME ) 0 (more than one message allocated); MC.MME != MC.MMC (messages allocated not equal to number requested). When this bit is set to 1, single MSI mode operation is in use and software is responsible for clearing bits in the IS register to clear interrupts. This bit shall be cleared to 0 by hardware when any of the four conditions stated is false. This bit is also cleared to 0 when MC.MSIE = 1 and MC.MME = 0h. In this case, the hardware has been programmed to use single MSI mode, and is not reverting to that mode. The HBA shall always revert to single MSI mode when the number of vectors allocated by the host is leass than the number requested. Value of MRSM is a don't care when GHC.HR=1. |
| 1 | 0h<br>RW | **Interrupt Enable (IE):** This global bit enables interrupts from the HBA. When cleared (reset default), all interrupt sources from all ports are disabled. When set, interrupts are enabled. |
| 0 | 0h<br>RW/1S | **HBA Reset (HR):** When set by SW, this bit causes an internal reset of the HBA. All state machines that relate to data transfers and native command queuing will return to an idle condition, and all ports will be re-initialized via COMRESET. When the HBA has performed the reset action, it will reset this bit to 0. A software write of 0 will have no effect. For a description on which bits are reset when this bit is set, see the AHCI specification, section 10.3.3. |

## 17.8.3 Interrupt Status (IS)—Offset 8h

This register indicates which of the ports within the controller have an interrupt pending and require service.



### Access Method

**Type:** Memory Mapped I/O Register (Size: 32 bits)

**IS:** [ABAR] + 8h

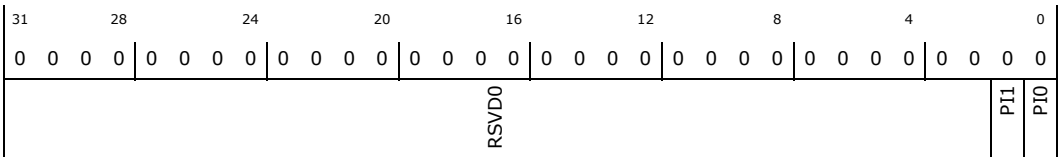
**ABAR Type:** PCI Configuration Register (Size: 32 bits)
**ABAR Reference:** [B:0, D:19, F:0] + 24h

**Default:** 00000000h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31:2 | 0b<br>RO | **RSVD0:** Reserved |
| 1 | 0h<br>RW/1C | **Interrupt Pending Status Port 1 (IPS1):** If set, indicates that port 1 has an interrupt pending. Software can use this information to determine which ports require service after an interrupt. This bit is only applicable to project(s): That has port 1 physically. |
| 0 | 0h<br>RW/1C | **Interrupt Pending Status Port 0 (IPS0):** If set, indicates that port 0 has an interrupt pending. Software can use this information to determine which ports require service after an interrupt. This bit is only applicable to project(s): That has port 0 physically. |

## 17.8.4 Ports Implemented (GHC_PI)—Offset Ch

This register indicates which ports are exposed to the HBA. It is loaded by platform BIOS. It indicates which ports that the device supports are available for software to use. Any available port may not be implemented. There is BIOS programming requirement on the PI register. Please refer to section 7.9.13.1.1 for details.



### Access Method

**Type:** Memory Mapped I/O Register (Size: 32 bits)

**GHC_PI:** [ABAR] + Ch

**ABAR Type:** PCI Configuration Register (Size: 32 bits)
**ABAR Reference:** [B:0, D:19, F:0] + 24h

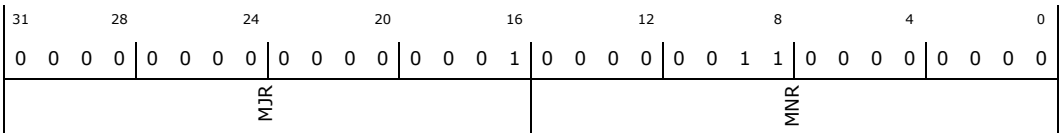
**Default:** 00000000h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31:2 | 0b<br>RO | **RSVD0:** Reserved |

| Bit Range | Default & Access | Description |
|---|---|---|
| 1 | 0h<br>RW/O | **Port 1 Implemented (PI1):** If set, then port 1 is available for use. If cleared, the port is not available for use. This bit is reserved and is read-only 0 if below condition is true else it's RWO-zero: Refer to CAP.NP where port 1 is not available. |
| 0 | 0h<br>RW/O | **Port 0 Implemented (PI0):** If set, then port 0 is available for use. If cleared, the port is not available for use. This bit is reserved and is read-only 0 if below condition is true else it's RWO-zero: Refer to CAP.NP where port 0 is not available. |

## 17.8.5 AHCI Version (VS)—Offset 10h

This register indicates the major and minor version of the AHCI specification. It is BCD encoded. The upper two bytes represent the major version number, and the lower two bytes represent the minor version number. Example: Version 3.12 would be represented as 00030102h.



### Access Method

**Type:** Memory Mapped I/O Register (Size: 32 bits)

**VS:** [ABAR] + 10h

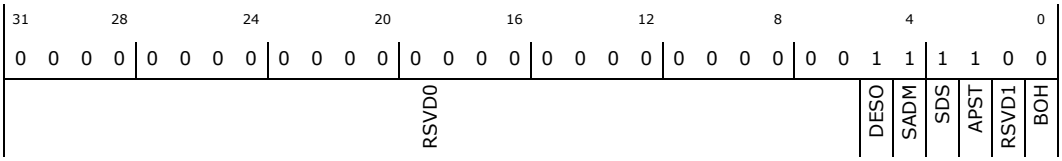
**ABAR Type:** PCI Configuration Register (Size: 32 bits)
**ABAR Reference:** [B:0, D:19, F:0] + 24h

**Default:** 00010300h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31:16 | 0001h<br>RO | **Major Version Number (MJR):** Indicates the major version is 1 |
| 15:0 | 0300h<br>RO | **Minor Version Number (MNR):** Indicates the minor version is 30 |

## 17.8.6 HBA Capabilities Extended (GHC_CAP2)—Offset 24h

This register indicates basic capabilities of the HBA to driver software. The RWO bits in this register are only cleared upon Backbone Reset.



### Access Method

**Type:** Memory Mapped I/O Register (Size: 32 bits)

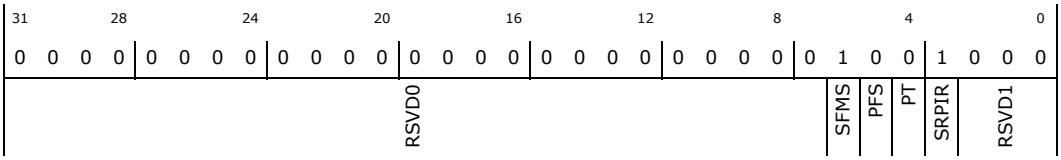
**GHC_CAP2:** [ABAR] + 24h

**ABAR Type:** PCI Configuration Register (Size: 32 bits)
**ABAR Reference:** [B:0, D:19, F:0] + 24h

**Default:** 0000003Ch

| Bit Range | Default & Access | Description |
|---|---|---|
| 31:6 | 0b<br>RO | **RSVD0:** Reserved |
| 5 | 1h<br>RW/O | **DEVSLP Entrance from Slumber Only (DESO):** This field specifies that the HBA shall only assert DEVSLP if the interface is in Slumber. When this bit is set to 1, the HBA shall ignore software directed entrance to DEVSLP via PxCMD.ICC unless PxSSTS.IPM = 6h. When this bit is cleared to 0, the HBA may enter DEVSLP from any link state (active, Partial, or Slumber). BIOS is requested to program this field to 1. |
| 4 | 1h<br>RW/O | **Supports Aggressive DEVSLP Management (SADM):** When set to 1, the HBA supports hardware assertion of the DEVSLP signal after the idle timeout expires. When cleared to 0, this function is not supported and software shall treat the PxDEVSLP.ADSE field as reserved. Note: If PHY IO PM Disable Fuse is 1, this register will read 0. Else this register will read 1 with RWO attribute. |
| 3 | 1h<br>RW/O | **Supports DEVSLP (SDS):** When set to 1, the HBA supports the DEVSLP feature. When cleared to 0, DEVSLP is not supported. Note: If PHY IO PM Disable Fuse is 1, this register will read 0. Else this register will read 1 with RWO attribute. |
| 2 | 1h<br>RW/O | **Automatic Partial to Slumber Transitions (APST):** When set to 1, the HBA supports Automatic Partial to Slumber Transitions. When cleared to 0, Automatic Partial to Slumber Transition is not supported. Note: If SATA PHY PM Disable Fuse is 1, this register will read only 0. Else this register will read 1 with RWO attribute. |
| 1 | 0b<br>RO | **RSVD1:** Reserved |
| 0 | 0h<br>RO | **BIOS/OS Handoff (BOH):** Not supported. |

## 17.8.7 Vendor Specific (VSP)—Offset A0h



### Access Method

**Type:** Memory Mapped I/O Register (Size: 32 bits)

**VSP:** [ABAR] + A0h

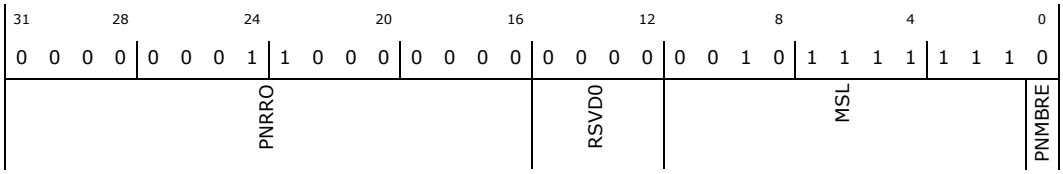
**ABAR Type:** PCI Configuration Register (Size: 32 bits)
**ABAR Reference:** [B:0, D:19, F:0] + 24h

**Default:** 00000048h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31:7 | 0b<br>RO | **RSVD0:** Reserved |
| 6 | 1h<br>RO | **Software Feature Mask Supported (SFMS):** Set to 1 if the platform is enabled for premium storage features mask (SFM) as described in VS MMIO space at offset ABAR[RPID.(OFST*4)+4]. |
| 5 | 0h<br>RO | **Premium Features Supported (PFS):** Set to 1 if the platform is enabled for premium storage features (PFB) as described in VS MMIO space at offset ABAR[RPID.OFST*4]. Set to 0 if the platform is not enabled for premium storage features. |
| 4 | 0h<br>RO | **Platform Type (PT):** Set to 1 if mobile platform. Clear (0) if desktop. |

| Bit Range | Default & Access | Description |
|---|---|---|
| 3 | 1h<br>RO | **Supports RAID Platform ID Reporting (SRPIR):** If set to 1, then indicates that the RAID Platform ID is reported via ABAR + C0h. Set to 0 if this ID is not reported via MMIO space. |
| 2:0 | 0b<br>RO | **RSVD1:** Reserved |

## 17.8.8 Vendor Specific Capabilities (VS_CAP)—Offset A4h



### Access Method

**Type:** Memory Mapped I/O Register (Size: 32 bits)

**VS_CAP:** [ABAR] + A4h

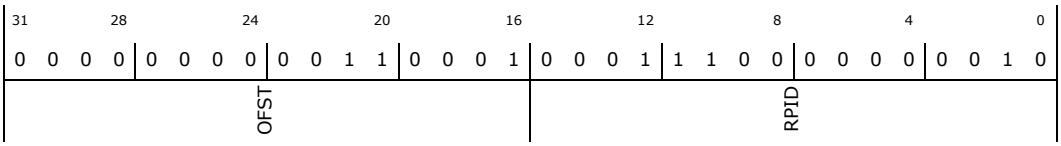
**ABAR Type:** PCI Configuration Register (Size: 32 bits)
**ABAR Reference:** [B:0, D:19, F:0] + 24h

**Default:** 018002FEh

| Bit Range | Default & Access | Description |
|---|---|---|
| 31:16 | 0180h<br>RO | **PCIe NAND Remapped Register Offset (PNRRO):** Specifies the DWORD offset within ABAR as to where the PCIe NAND AHCI BAR register space is remapped. Only valid when PNABRE = 1. This places the start of the PCIe NAND AHCI BAR register space at ABAR + 600h |
| 15:12 | 0b<br>RO | **RSVD0:** Reserved |
| 11:1 | 17Fh<br>RW | **Memory Space Limit. (MSL):** This field specifies the size of the remapped memory space for the PCIe NAND device. It is a 0-based field. Memory BAR offset from 0 to MSL of the PCIe NAND device are remapped under the integrated AHCI controller memory space. The remapped offset into the AHCI memory space and the value programmed in this field must not exceed the allocated 2k AHCI memory space of the integrated AHCI controller. The reset default of this field is 17Fh (i.e. bit[11:1] = 00101111111b) which specifies the size of the remapped memory space as 384 bytes. |
| 0 | 0h<br>RW/O | **PCIe NAND Memory BAR Remapped Enable (PNMBRE):** Set to 1 if a PCIe NAND device is present and remapping of its memory BAR register space is enabled. Cleared to 0 if there is no PCIe NAND device present or the remapping of its memory BAR register space is disabled. |

## 17.8.9 RAID Platform ID (RPID)—Offset C0h

This register is used by the Intel Matrix Storage Manager OROM to match the features supported by the OROM with the platform on which the OROM is executing. This prevents the use of an OROM designed for newer chipsets from being use on older chipsets as this could reduce up-sell potential.



### Access Method

**Type:** Memory Mapped I/O Register (Size: 32 bits)

**RPID:** [ABAR] + C0h

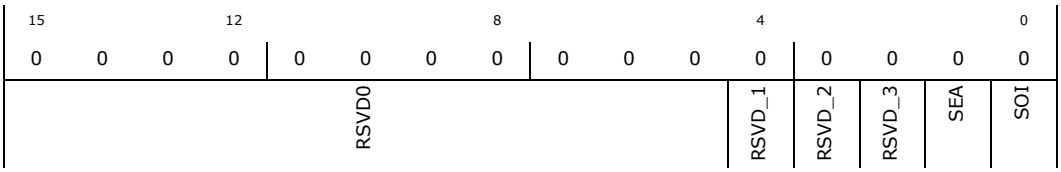
**ABAR Type:** PCI Configuration Register (Size: 32 bits)
**ABAR Reference:** [B:0, D:19, F:0] + 24h

**Default:** 00311C02h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31:16 | 0031h<br>RO | **Offset (OFST):** The offset of the Premium Feature Block (PFB) in DWords from the beginning of the ABAR. SFM follows directly after PFB. |
| 15:0 | 1C02h<br>RO | **RAID Platform ID (RPID):** Specifies the DID value that has been assigned to the platform. This is the same DID that is reported by the SATA controller when SATAGC.AIE is set to 1 except that the DID is always reported through this register, regardless if the programming of SATAGC.AIE. |

## 17.8.10 Premium Feature Block (PFB)—Offset C4h

These registers indicate to the Intel Rapid Storage Technology AHCI driver that those premium RAID features that can be supported on the platform.



### Access Method

**Type:** Memory Mapped I/O Register (Size: 16 bits)

**PFB:** [ABAR] + C4h

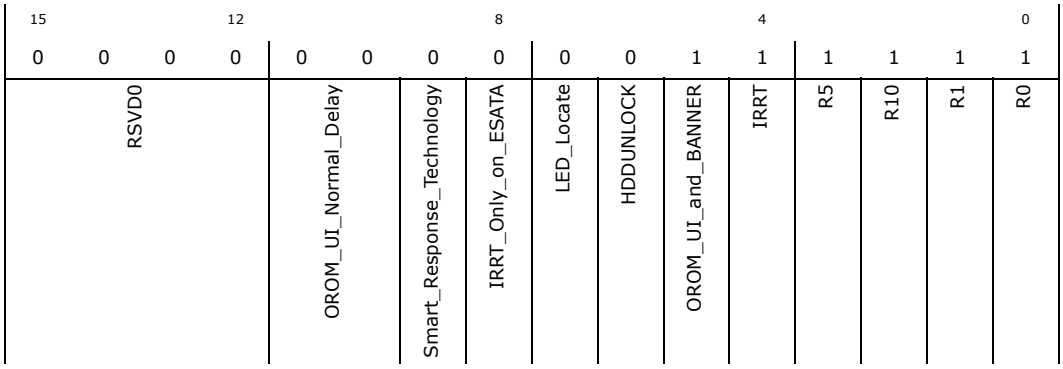
**ABAR Type:** PCI Configuration Register (Size: 32 bits)
**ABAR Reference:** [B:0, D:19, F:0] + 24h

**Default:** 0000h

| Bit Range | Default & Access | Description |
|---|---|---|
| 15:5 | 0b<br>RO | **RSVD0:** Reserved |
| 4 | 0h<br>RO | **Reserved (RSVD_1):** Read value is the same as VSP.PFS. |
| 3 | 0h<br>RO | **Reserved (RSVD_2):** Read value is the same as VSP.PFS. |
| 2 | 0h<br>RO | **Reserved (RSVD_3):** Read value is the same as VSP.PFS. |
| 1 | 0h<br>RO | **Supports Email Alert (SEA):** Read value is the same as VSP.PFS. If set to 1, then this feature is supported as part of the premium feature set. |
| 0 | 0h<br>RO | **Supports OEM IOCTL (SOI):** Read value is the same as VSP.PFS. If set to 1, then this feature is supported as part of the premium feature set. |

## 17.8.11 SW Feature Mask (SFM)—Offset C8h

The following will be programmed by the BIOS when VS_CAP.SFMS == 1. The feature mask is used by SW to determine which non-premium features shall be supported by SW.



### Access Method

**Type:** Memory Mapped I/O Register (Size: 16 bits)

**SFM:** [ABAR] + C8h

**ABAR Type:** PCI Configuration Register (Size: 32 bits)
**ABAR Reference:** [B:0, D:19, F:0] + 24h

**Default:** 003Fh

| Bit Range | Default & Access | Description |
|---|---|---|

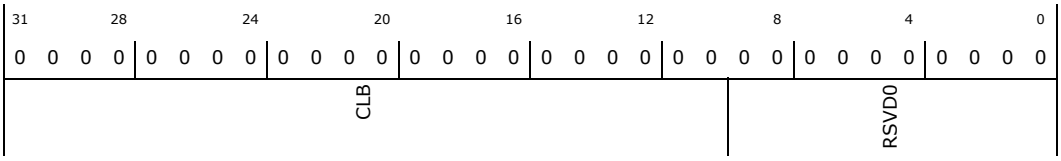
| 11:10 | 0h<br>RW/O | **OROM UI Normal Delay. (OROM_UI_Normal_Delay):** Values of these bits specify the delay of the OROM UI Splash Screen in a normal status. 00 = 2 secs (default and previous value); 01 = 4 secs; 10 = 6 secs; 11 = 8 secs. If bit 5 == 0, then these values are disregarded. |
| 9 | 0h<br>RW/O | **Smart Response Technology. (Smart_Response_Technology):** If set to 1, then Smart Response Technology is enabled. If cleared to 0, the feature is disabled. |
| 8 | 0h<br>RW/O | **RRT Only on ESATA (IRRT_Only_on_ESATA):** If set to 1, then only RRT volumes can span internal and external SATA ports. If cleared to 0, then any RAID volume can span internal and external SATA ports. |
| 7 | 0h<br>RW/O | **LED Locate (LED_Locate):** If set to 1, then LED/SGPIO hardware is attached and the ping to locate feature is enabled in the OS. |
| 6 | 0h<br>RW/O | **HDDUNLOCK:** If set to 1, then HDD password unlock is enabled in the OS. |
| 5 | 1h<br>RW/O | **OROM UI and BANNER (OROM_UI_and_BANNER):** If set to 1, then the OROM UI is displayed. When cleared to 0, the OROM UI and BANNER are not displayed if all disks and volumes have a normal status. |
| 4 | 1h<br>RW/O | **RRT (IRRT):** If set to 1, then Rapid Recovery Technology is enabled. |
| 3 | 1h<br>RW/O | **R5:** If set to 1, then RAID5 is enabled |
| 2 | 1h<br>RW/O | **R10:** If set to 1, then RAID10 is enabled |

| Bit Range | Default & Access | Description |
|---|---|---|
| 1 | 1h RW/O | **R1:** If set to 1, then RAID1 is enabled |
| 0 | 1h RW/O | **R0:** If set to 1, then RAID0 is enabled |

## 17.8.12 Port-Command List Base Address (PxCLB0)—Offset 100h



### Access Method

**Type:** Memory Mapped I/O Register (Size: 32 bits)

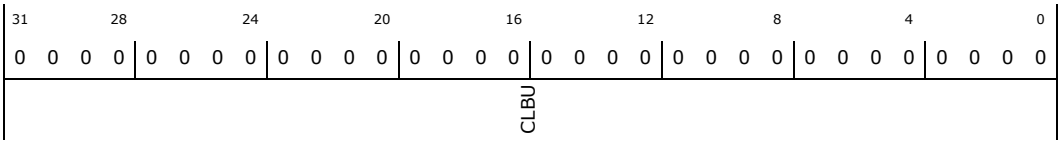
**PxCLB0:** [ABAR] + 100h

**ABAR Type:** PCI Configuration Register (Size: 32 bits)
**ABAR Reference:** [B:0, D:19, F:0] + 24h

**Default:** 00000000h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31:10 | 000000h RW | **Command List Base Address (CLB):** Indicates the 32-bit base for the command list for this port. This base is used when fetching commands to execute. This address must be 1K aligned as indicated by bits 31:10 being read/write. Note that these bits are not reset on a HBA reset. |
| 9:0 | 0b RO | **RSVD0:** Reserved |

## 17.8.13 Port-Command List Base Address Upper 32-bits (PxCLBU0)—Offset 104h



### Access Method

**Type:** Memory Mapped I/O Register (Size: 32 bits)

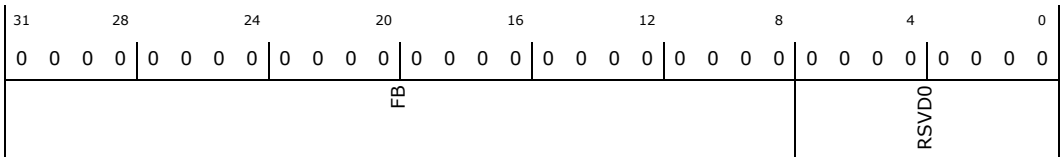
**PxCLBU0:** [ABAR] + 104h

**ABAR Type:** PCI Configuration Register (Size: 32 bits)
**ABAR Reference:** [B:0, D:19, F:0] + 24h

**Default:** 00000000h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31:0 | 00000000h RW | **Command List Base Address Upper (CLBU):** Indicates the upper 32-bits for the command list base address for this port. This base is used when fetching commands to execute. Note that these bits are not reset on a HBA reset. |

## 17.8.14 Port-FIS Base Address (PxFB0)—Offset 108h



### Access Method

**Type:** Memory Mapped I/O Register (Size: 32 bits)

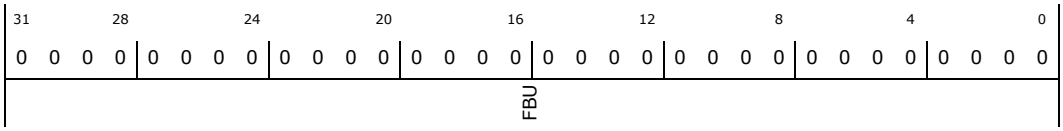
**PxFB0:** [ABAR] + 108h

**ABAR Type:** PCI Configuration Register (Size: 32 bits)
**ABAR Reference:** [B:0, D:19, F:0] + 24h

**Default:** 00000000h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31:8 | 0000000h RW | **FIS Base Address (FB):** Indicates the 32-bit base for received FISes. This address must be 256-byte aligned as indicated by bits 31:08 being read/write. When FIS-based switching is in use, this structure is 4KB in length and the address shall be 4KB aligned. Note that these bits are not reset on a HBA reset. |
| 7:0 | 0b RO | **RSVD0:** Reserved |

## 17.8.15 Port-FIS Base Address Upper 32-bits (PxFBU0)—Offset 10Ch



### Access Method

**Type:** Memory Mapped I/O Register (Size: 32 bits)

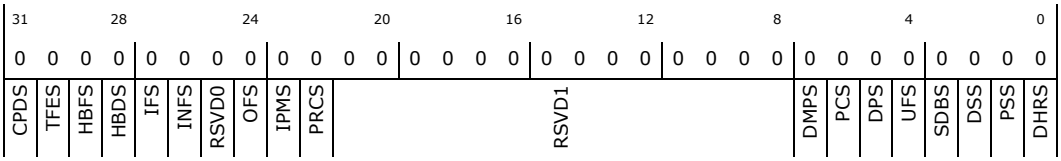
**PxFBU0:** [ABAR] + 10Ch

**ABAR Type:** PCI Configuration Register (Size: 32 bits)
**ABAR Reference:** [B:0, D:19, F:0] + 24h

**Default:** 00000000h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31:0 | 00000000h RW | **FIS Base Address Upper (FBU):** Indicates the upper 32-bits for the received FIS base for this port. Note that these bits are not reset on a HBA reset. |

## 17.8.16 Port-Interrupt Status (PxIS0)—Offset 110h



### Access Method

**Type:** Memory Mapped I/O Register (Size: 32 bits)

**PxIS0:** [ABAR] + 110h

**ABAR Type:** PCI Configuration Register (Size: 32 bits)
**ABAR Reference:** [B:0, D:19, F:0] + 24h

**Default:** 00000000h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31 | 0h<br>RO | **Cold Presence Detect Status (CPDS):** The SATA controller does not support cold presence detect. |
| 30 | 0h<br>RW/1C | **Task File Error Status (TFES):** This bit is set whenever the status register is updated by the device and the error bit (bit 0 of the Status field in the received FIS) is set. |
| 29 | 0h<br>RW/1C | **Host Bus Fatal Error Status (HBFS):** Indicates that the HBA encountered a host bus error that it cannot recover from, such as a bad software pointer. In PCI, such an indication would be a target or master abort. |
| 28 | 0h<br>RW/1C | **Host Bus Data Error Status (HBDS):** Indicates that the HBA encountered a data error (uncorrectable ECC / parity) when reading from or writing to system memory. |
| 27 | 0h<br>RW/1C | **Interface Fatal Error Status (IFS):** Indicates that the HBA encountered an error on the SATA interface which caused the transfer to stop. |
| 26 | 0h<br>RW/1C | **Interface Non-fatal Error Status (INFS):** Indicates that the HBA encountered an error on the SATA interface but was able to continue operation. |
| 25 | 0b<br>RO | **RSVD0:** Reserved |
| 24 | 0h<br>RW/1C | **Overflow Status (OFS):** Indicates that the HBA received more bytes from a device than was specified in the PRD table for the command. |

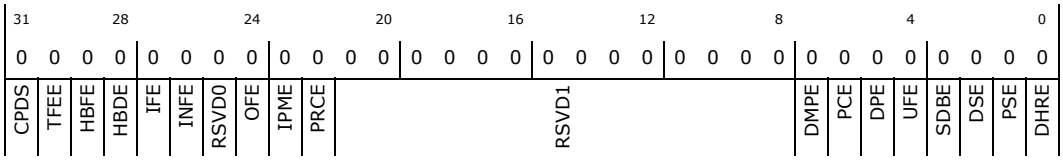
| 22 | 0h<br>RO | **PhyRdy Change Status (PRCS):** When set to one indicates the internal PhyRdy signal changed state. This bit reflects the state of PxSERR.DIAG.N. This bit is RO and is only cleared when PxSERR.DIAG.N is cleared. |
| 21:8 | 0b<br>RO | **RSVD1:** Reserved |
| 7 | 0h<br>RW/1C | **Device Mechanical Presence Status (DMPS):** When set, indicates that a platform mechanical presence switch has been opened or closed, which may lead to a change in the connection state of the device. This bit is only valid in systems that support mechanical presence switch (CAP.SMPS and PxCMD.MPSP are set). |
| 6 | 0h<br>RO | **Port Connect Change Status (PCS):** 1=Change in Current Connect Status. 0=No change in Current Connect Status. This bit reflects the state of PxSERR.DIAG.X. This bit is only cleared when PxSERR.DIAG.X is cleared. |
| 5 | 0h<br>RW/1C | **Descriptor Processed (DPS):** A PRD with the I. bit set has transferred all of its data. |
| 4 | 0h<br>RO | **Unknown FIS Interrupt (UFS):** When set to 1 indicates that an unknown FIS was received and has been copied into system memory. This bit is cleared to 0 by software clearing the PxSERR.DIAG.F bit to 0. Note that this bit does not directly reflect the PxSERR.DIAG.F bit. PxSERR.DIAG.F is set immediately when an unknown FIS is detected, whereas this bit is set when the FIS is posted to memory. Software should wait to act on an unknown FIS until this bit is set to 1 or the two bits may become out of sync. |
| 3 | 0h<br>RW/1C | **Set Device Bits Interrupt (SDBS):** A Set Device Bits FIS has been received with the I. bit set and has been copied into system memory. |
| 2 | 0h<br>RW/1C | **DMA Setup FIS Interrupt (DSS):** A DMA Setup FIS has been received with the I. bit set and has been copied into system memory. |

| Bit Range | Default & Access | Description |
|---|---|---|
| 1 | 0h<br>RW/1C | **PIO Setup FIS Interrupt (PSS):** A PIO Setup FIS has been received with the I. bit set, it has been copied into system memory, and the data related to that FIS has been transferred. This bit shall be set even if the data transfer resulted in an error. |
| 0 | 0h<br>RW/1C | **Device to Host Register FIS Interrupt (DHRS):** A D2H register FIS has been received with the I. bit set, and has been copied into system memory. |

## 17.8.17 Port-Interrupt Enable (PxIE0)—Offset 114h



### Access Method

**Type:** Memory Mapped I/O Register (Size: 32 bits)

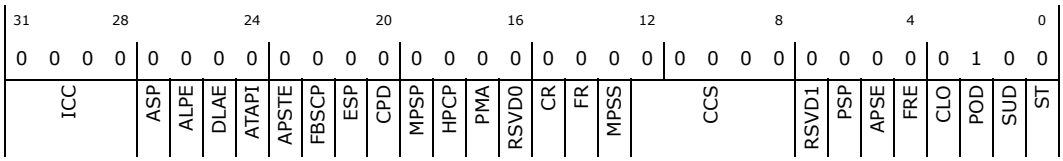
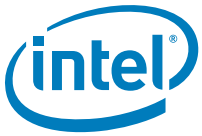
## 17.8.18 Port-Command (PxCMD0)—Offset 118h



### Access Method

**Type:** Memory Mapped I/O Register (Size: 32 bits)



**PxCMD0:** [ABAR] + 118h

**ABAR Type:** PCI Configuration Register (Size: 32 bits)
**ABAR Reference:** [B:0, D:19, F:0] + 24h

**Default:** 00000004h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31:28 | 0h<br>RW | **Interface Communication Control (ICC):** This is a four bit field which can be used to control reset and power states of the interface. If the Link layer is currently in the L_IDLE state, writes to this field shall cause the HBA to initiate a transition to the interface power management state requested. If the Link layer is not currently in the L_IDLE state, writes to this field shall have no effect. Fh -9h Reserved. 8h DEVSLP: This shall cause the HBA to assert the DEVSLP signal associated with the port; the HBA shall ignore the DEVSLP Idle Timeout value specified by PxDEVSLP.DITO. Software shall only request DEVSLP when the interface is in an idle state (i.e. PxCI is cleared to 0h and PxSACT is cleared to 0h); if the interface is not idle at the time the register is written, then the HBA takes no action and the interface remains in its current state. If PxCAP2.DESO is set to '1' and PxSSTS.IPM is not set to '6h', then the HBA takes no action and the interface remains in its current state. Additionally, the HBA shall not assert the DEVSLP signal until PHYRDY has been achieved (after a previous de-assertion). 7h Reserved 6h Slumber: This shall cause the HBA to request a transition of the interface to the Slumber state. The SATA device may reject the request and the interface shall remain in its current state. 5h-3h Reserved. 2h Partial: This shall cause the HBA to request a transition of the interface to the Partial state. The SATA device may reject the request and the interface shall remain in its current state. 1h Active: This shall cause the HBA to request a transition of the interface into the active state. If the requested transition is from the DEVSLP state, then the HBA shall wait until PxDEVSLP.DMAT has expired before de-asserting the DEVSLP signal. 0h No-Op / Idle: When software reads this value, it indicates the HBA is ready to accept a new interface control command, although the transition to the previously selected state may not yet have occurred. When system software writes a non-reserved value other than No-Op (0h), the HBA shall perform the action and update this field back to Idle (0h). If software writes to this field to change the state to a state the link is already in (i.e. interface is in the active state and a request is made to go to the active state), the HBA shall take no action and return this field to Idle. If the interface is in a low power state and the software wants to transition to a different low power state, software must first bring the link to active and then initiate the transition to the desired low power state (with the exception of DEVSLP). The transition to DEVSLP may occur from any other state if CAP2.DESO is cleared to '0'. If CAP2.DESO is set to '1', then DEVSLP may only be transitioned to if the link is in Slumber. |
| 27 | 0h<br>RW | **Aggressive Slumber Partial (ASP):** When set to 1, and the ALPE bit is set, the HBA shall aggressively enter Slumber state when it clears a bit in the PxCI or PxSACT register and the register values are 0h. When cleared, and the ALPE bit is set, the HBA will aggressively enter Partial state when it clears a bit in the PxCI or PxSACT register and the register values are both 0h. If CAP.SALP is cleard to 0, software shall treat this bit as reserved. |
| 26 | 0h<br>RW | **Aggressive Link Power Management Enable (ALPE):** When set, the HBA will aggressively enter a lower link power state (Partial or Slumber) based upon the setting of the ASP bit. |
| 25 | 0h<br>RW | **Drive LED on ATAPI Enable (DLAE):** When set, the HBA will drive the LED pin active for commands regardless of the state of PxCMD.ATAPI. When cleared, the HBA will only drive the LED pin active for commands if PxCMD.ATAPI is set to 0. This bit is set by software |

| Bit Range | Default & Access | Description |
|---|---|---|
| 24 | 0h<br>RW | **Device is ATAPI (ATAPI):** When set, the connected device is an ATAPI device. This bit is used by the HBA to control whether or not to generate the desktop LED when commands are active. |
| 23 | 0h<br>RW | **Automatic Partial to Slumber Transitions Enabled (APSTE):** When set to 1, the HBA may perform Automatic Partial to Slumber Transitions. When cleared to 0 - the port shall not perform Automatic Partial to Slumber Transitions. Software shall only set this bit to 1 - if CAP2.APST is set to 1; if CAP2.APST is cleared to 0 - software shall treat this bit as reserved. |
| 22 | 0h<br>RO | **FIS-based Switching Capable Port (FBSCP):** The SATA controller does not support FIS-Based Switching. |
| 21 | 0h<br>RW/O | **External SATA Port (ESP):** When set to 1, indicates that this port is routed externally and will be used with an external SATA device. When set to 1, CAP.SXS must also be set to 1. When cleared (0), indicates that this port is not routed externally and supports internal SATA devices only. If ESP is set to 1, then the port may experience hot plug events. |
| 20 | 0h<br>RO | **Cold Presence Detection (CPD):** The SATA controller does not support cold presence detect. |
| 19 | 0h<br>RW/O | **Mechanical Presence Switch Attached to Port (MPSP):** If set to 1, the platform supports a mechanical presence switch attached to this port. If cleared to 0, the platform does not support a mechanical presence switch attached to this port. |
| 18 | 0h<br>RW/O | **Hot Plug Capable Port (HPCP):** This indicates whether this port is connected to a device which can be hot plugged. SATA by definition is hot-pluggable, but not all platforms are constructed to allow the device to be removed (it may be screwed into the chassis, for example). This bit can be used by system software to indicate a feature such as eject device to the end-user. |
| 17 | 0h<br>RO | **Port Multiplier Attached (PMA):** Not supported |
| 16 | 0b<br>RO | **RSVD0:** Reserved |
| 15 | 0h<br>RO | **Command List Running (CR):** When this bit is set it indicates that the command list DMA engine for the port is running. |
| 14 | 0h<br>RO | **FIS Receive Running (FR):** When this bit is set it indicates that the FIS Receive DMA engine for the port is running. |
| 13 | 0h<br>RO | **Mechanical Presence Switch State (MPSS):** The MPSS bit reports the state of a mechanical presence switch attached to this port. If CAP.SMPS is set to 1 and the mechanical presence switch is closed then this bit is cleared to 0. If CAP.SMPS is set to 1 and the mechanical presence switch is open then this bit is set to 1. If CAP.SMPS is set to 0 then this bit is cleared to 0. Software should only use this bit if both CAP.SMPS and PxCMD.MPSP are set to 1. |
| 12:8 | 00h<br>RO | **Current Command Slot (CCS):** Indicates the current command slot the HBA is processing. This field is valid when the PxCMD.ST bit is set, and is constantly updated by the HBA. This field can be updated as soon as the HBA recognizes an active command slot, or at some point soon after when it begins processing the command. When PxCMD.ST transitions from a 1 to a 0, the HBA will reset this field to 0. After PxCMD.ST transitions from 0 to 1, the highest priority slot to issue from next is command slot 0. After the first command has been issued, the highest priority slot to issue from next is PxCMD.CCS + 1. For example, after the HBA has issued its first command, if PxCMD.CCS = 0h and PxCI is set to 3h, the next command that will be issued is from command slot 1. |
| 7 | 0b<br>RO | **RSVD1:** Reserved |
| 6 | 0h<br>RO | **PHYSLP Present (PSP):** If set to 1, the platform supports PHYSLP on this port. If cleared to 0, the platform does not support PHYSLP on this port. This bit may only be set to 1 if CAP2.SPS is set to 1. |

| Bit Range | Default & Access | Description |
|---|---|---|
| 5 | 0h<br>RW | **Aggressive PHYSLP Enable (APSE):** This bit is read/write for HBAs that support aggressive PHYSLP management (CAP2.SAPM == 1). This bit is read-only for HBAs that do not support aggressive PHYSLP management (CAP2.SPS == 0). When this bit is set to 1, the HBA shall assert the PHYSLP signal after the port has been idle (PxCI == 0h and PxSACT == 0h) for the amount of time specified by the GHC.PITO register. When this bit is cleared to 0, the HBA does not enter PHYSLP unless software directed via PxCMD.ICC. This bit shall only be set to 1 if PxCMD.PSP is set to 1. If this bit is set to 1 and software clears the bit to 0, then the HBA shall de-assert the PHYSLP signal if asserted. |
| 4 | 0h<br>RW | **FIS Receive Enable (FRE):** When set, the HBA may post received FISes into the FIS receive area pointed to by PxFB and PxFBU. When cleared, received FISes are not accepted by the HBA, except for the first D2H register FIS after the initialization sequence. |
| 3 | 0h<br>RW/1S | **Command List Override (CLO):** Setting this bit to 1 causes PxTFD.STS.BSY and PxTFD.STS.DRQ to be cleared to 0. This allows a software reset to be transmitted to the device regardless of whether the BSY and DRQ bits are still set in the PxTFD.STS register. The HBA sets this bit to 0 when PxTFD.STS.BSY and PxTFD.STS.DRQ have been cleared to 0. A write to this register with a value of 0 shall have no effect. |
| 2 | 1h<br>RO | **Power On Device (POD):** The SATA controller does not support cold presence detect. |
| 1 | 0h<br>RW | **Spin-Up Device (SUD):** This bit is read/write for HBAs that support staggered spin-up via CAP.SSS. This bit is read only 1 for HBAs that do not support staggered spin-up. On an edge detect from 0 to 1, the HBA shall start a COMRESET initialization sequence to the device. Clearing this bit causes no action on the interface. Clearing this bit to0 does not cause any OOB signal to be sent on the interface. When this bit is cleared to 0 and PxSCTL.DET = 0h, the HBA will enter listen mode. |
| 0 | 0h<br>RW | **Start (ST):** When set, the HBA may process the command list. When cleared, the HBA may not process the command list. Whenever this bit is changed from a 0 to a 1, the HBA starts processing the command list at entry 0. Whenever this bit is changed from a 1 to a 0, the PxCI and PxSACT register is cleared by the HBA upon the HBA putting the controller into an idle state. PxTFD shall be updated also. |

Bit Field 31:27 Reserved 26 Exchanged (X): When set to one this bit indicates that a change in device presence has been detected since the last time this bit was cleared. The means by which the implementation determines that the device presence has changed is vendor specific. This bit shall always be set to one anytime a COMINIT signal is received. This bit is reflected in the P0IS.PCS bit. 25 Unrecognized FIS Type (F): Indicates that one or more FISs were received by the Transport layer with good CRC, but had a type field that was not recognized. 24 Transport state transition error (T): Indicates that an error has occurred in the transition from one state to another within the Transport layer since the last time this bit was cleared. 23 Link Sequence Error (S): Indicates that one or more Link state machine error conditions were encountered. The Link Layer state machine defines the conditions under which the link layer detects an erroneous transition. 22 Handshake Error (H): Indicates that one or more R_ERR handshake response was received in response to frame transmission. Such errors may be the result of a CRC error detected by the recipient, a disparity or 8b/10b decoding error, or other error condition leading to a negative handshake on a transmitted frame. 21 CRC Error (C): Indicates that one or more CRC errors occurred with the Link Layer. 20 Disparity Error (D): This field is not used by AHCI. 19 10B to 8B Decode Error (B): Indicates that one or more 10B to 8B decoding errors occurred. 18 Comm Wake (W): Indicates that a Comm Wake signal was detected by the Phy. 17 Phy Internal Error (I): Indicates that the Phy detected some internal error. 16 PhyRdy Change (N): When set to 1 this bit indicates that the internal PhyRdy signal changed state since the last time this bit was cleared. The state of this bit is reflected in the PxIS.PRCS interrupt status bit and an interrupt will be generated if enabled. |

| 4 | 0h<br>RO | **Unknown FIS Interrupt (UFS):** When set to 1 indicates that an unknown FIS was received and has been copied into system memory. This bit is cleared to 0 by software clearing the PxSERR.DIAG.F bit to 0. Note that this bit does not directly reflect the PxSERR.DIAG.F bit. PxSERR.DIAG.F is set immediately when an unknown FIS is detected, whereas this bit is set when the FIS is posted to memory. Software should wait to act on an unknown FIS until this bit is set to 1 or the two bits may become out of sync. |

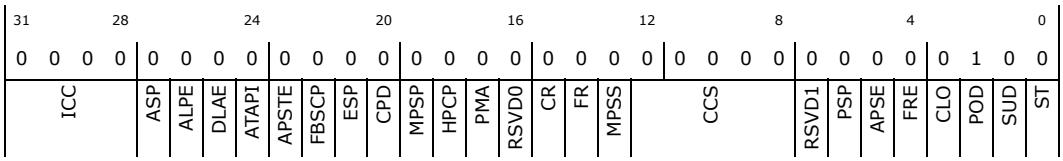
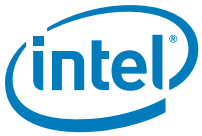
## 17.8.33 Port-Command (PxCMD1)—Offset 198h



### Access Method

**Type:** Memory Mapped I/O Register (Size: 32 bits)



**PxCMD1:** [ABAR] + 198h

**ABAR Type:** PCI Configuration Register (Size: 32 bits)
**ABAR Reference:** [B:0, D:19, F:0] + 24h

**Default:** 00000004h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31:28 | 0h<br>RW | **Interface Communication Control (ICC):** This is a four bit field which can be used to control reset and power states of the interface. If the Link layer is currently in the L_IDLE state, writes to this field shall cause the HBA to initiate a transition to the interface power management state requested. If the Link layer is not currently in the L_IDLE state, writes to this field shall have no effect. Fh -9h Reserved. 8h DEVSLP: This shall cause the HBA to assert the DEVSLP signal associated with the port; the HBA shall ignore the DEVSLP Idle Timeout value specified by PxDEVSLP.DITO. Software shall only request DEVSLP when the interface is in an idle state (i.e. PxCI is cleared to 0h and PxSACT is cleared to 0h); if the interface is not idle at the time the register is written, then the HBA takes no action and the interface remains in its current state. If PxCAP2.DESO is set to '1' and PxSSTS.IPM is not set to '6h', then the HBA takes no action and the interface remains in its current state. Additionally, the HBA shall not assert the DEVSLP signal until PHYRDY has been achieved (after a previous de-assertion). 7h Reserved 6h Slumber: This shall cause the HBA to request a transition of the interface to the Slumber state. The SATA device may reject the request and the interface shall remain in its current state. 5h-3h Reserved. 2h Partial: This shall cause the HBA to request a transition of the interface to the Partial state. The SATA device may reject the request and the interface shall remain in its current state. 1h Active: This shall cause the HBA to request a transition of the interface into the active state. If the requested transition is from the DEVSLP state, then the HBA shall wait until PxDEVSLP.DMAT has expired before de-asserting the DEVSLP signal. 0h No-Op / Idle: When software reads this value, it indicates the HBA is ready to accept a new interface control command, although the transition to the previously selected state may not yet have occurred. When system software writes a non-reserved value other than No-Op (0h), the HBA shall perform the action and update this field back to Idle (0h). If software writes to this field to change the state to a state the link is already in (i.e. interface is in the active state and a request is made to go to the active state), the HBA shall take no action and return this field to Idle. If the interface is in a low power state and the software wants to transition to a different low power state, software must first bring the link to active and then initiate the transition to the desired low power state (with the exception of DEVSLP). The transition to DEVSLP may occur from any other state if CAP2.DESO is cleared to '0'. If CAP2.DESO is set to '1', then DEVSLP may only be transitioned to if the link is in Slumber. |

| Bit Range | Default & Access | Description |
|---|---|---|
| 27 | 0h<br>RW | **Aggressive Slumber Partial (ASP):** When set to 1, and the ALPE bit is set, the HBA shall aggressively enter Slumber state when it clears a bit in the PxCI or PxSACT register and the register values are 0h. When cleared, and the ALPE bit is set, the HBA will aggressively enter Partial state when it clears a bit in the PxCI or PxSACT register and the register values are both 0h. If CAP.SALP is cleard to 0, software shall treat this bit as reserved. |
| 26 | 0h<br>RW | **Aggressive Link Power Management Enable (ALPE):** When set, the HBA will aggressively enter a lower link power state (Partial or Slumber) based upon the setting of the ASP bit. |
| 25 | 0h<br>RW | **Drive LED on ATAPI Enable (DLAE):** When set, the HBA will drive the LED pin active for commands regardless of the state of PxCMD.ATAPI. When cleared, the HBA will only drive the LED pin active for commands if PxCMD.ATAPI is set to 0. This bit is set by software |
| 24 | 0h<br>RW | **Device is ATAPI (ATAPI):** When set, the connected device is an ATAPI device. This bit is used by the HBA to control whether or not to generate the desktop LED when commands are active. |
| 23 | 0h<br>RW | **Automatic Partial to Slumber Transitions Enabled (APSTE):** When set to 1, the HBA may perform Automatic Partial to Slumber Transitions. When cleared to 0 - the port shall not perform Automatic Partial to Slumber Transitions. Software shall only set this bit to 1 - if CAP2.APST is set to 1; if CAP2.APST is cleared to 0 - software shall treat this bit as reserved. |
| 22 | 0h<br>RO | **FIS-based Switching Capable Port (FBSCP):** The SATA controller does not support FIS-Based Switching. |
| 21 | 0h<br>RW/O | **External SATA Port (ESP):** When set to 1, indicates that this port is routed externally and will be used with an external SATA device. When set to 1, CAP.SXS must also be set to 1. When cleared (0), indicates that this port is not routed externally and supports internal SATA devices only. If ESP is set to 1, then the port may experience hot plug events. |
| 20 | 0h<br>RO | **Cold Presence Detection (CPD):** The SATA controller does not support cold presence detect. |
| 19 | 0h<br>RW/O | **Mechanical Presence Switch Attached to Port (MPSP):** If set to 1, the platform supports a mechanical presence switch attached to this port. If cleared to 0, the platform does not support a mechanical presence switch attached to this port. |
| 18 | 0h<br>RW/O | **Hot Plug Capable Port (HPCP):** This indicates whether this port is connected to a device which can be hot plugged. SATA by definition is hot-pluggable, but not all platforms are constructed to allow the device to be removed (it may be screwed into the chassis, for example). This bit can be used by system software to indicate a feature such as eject device to the end-user. |
| 17 | 0h<br>RO | **Port Multiplier Attached (PMA):** Not supported |
| 16 | 0b<br>RO | **RSVD0:** Reserved |
| 15 | 0h<br>RO | **Command List Running (CR):** When this bit is set it indicates that the command list DMA engine for the port is running. |
| 14 | 0h<br>RO | **FIS Receive Running (FR):** When this bit is set it indicates that the FIS Receive DMA engine for the port is running. |
| 13 | 0h<br>RO | **Mechanical Presence Switch State (MPSS):** The MPSS bit reports the state of a mechanical presence switch attached to this port. If CAP.SMPS is set to 1 and the mechanical presence switch is closed then this bit is cleared to 0. If CAP.SMPS is set to 1 and the mechanical presence switch is open then this bit is set to 1. If CAP.SMPS is set to 0 then this bit is cleared to 0. Software should only use this bit if both CAP.SMPS and PxCMD.MPSP are set to 1. |

| Bit Range | Default & Access | Description |
|---|---|---|
| 12:8 | 00h<br>RO | **Current Command Slot (CCS):** Indicates the current command slot the HBA is processing. This field is valid when the PxCMD.ST bit is set, and is constantly updated by the HBA. This field can be updated as soon as the HBA recognizes an active command slot, or at some point soon after when it begins processing the command. When PxCMD.ST transitions from a 1 to a 0, the HBA will reset this field to 0. After PxCMD.ST transitions from 0 to 1, the highest priority slot to issue from next is command slot 0. After the first command has been issued, the highest priority slot to issue from next is PxCMD.CCS + 1. For example, after the HBA has issued its first command, if PxCMD.CCS = 0h and PxCI is set to 3h, the next command that will be issued is from command slot 1. |
| 7 | 0b<br>RO | **RSVD1:** Reserved |
| 6 | 0h<br>RO | **PHYSLP Present (PSP):** If set to 1, the platform supports PHYSLP on this port. If cleared to 0, the platform does not support PHYSLP on this port. This bit may only be set to 1 if CAP2.SPS is set to 1. |
| 5 | 0h<br>RW | **Aggressive PHYSLP Enable (APSE):** This bit is read/write for HBAs that support aggressive PHYSLP management (CAP2.SAPM == 1). This bit is read-only for HBAs that do not support aggressive PHYSLP management (CAP2.SPS == 0). When this bit is set to 1, the HBA shall assert the PHYSLP signal after the port has been idle (PxCI == 0h and PxSACT == 0h) for the amount of time specified by the GHC.PITO register. When this bit is cleared to 0, the HBA does not enter PHYSLP unless software directed via PxCMD.ICC. This bit shall only be set to 1 if PxCMD.PSP is set to 1. If this bit is set to 1 and software clears the bit to 0, then the HBA shall de-assert the PHYSLP signal if asserted. |
| 4 | 0h<br>RW | **FIS Receive Enable (FRE):** When set, the HBA may post received FISes into the FIS receive area pointed to by PxFB and PxFBU. When cleared, received FISes are not accepted by the HBA, except for the first D2H register FIS after the initialization sequence. |
| 3 | 0h<br>RW/1S | **Command List Override (CLO):** Setting this bit to 1 causes PxTFD.STS.BSY and PxTFD.STS.DRQ to be cleared to 0. This allows a software reset to be transmitted to the device regardless of whether the BSY and DRQ bits are still set in the PxTFD.STS register. The HBA sets this bit to 0 when PxTFD.STS.BSY and PxTFD.STS.DRQ have been cleared to 0. A write to this register with a value of 0 shall have no effect. |
| 2 | 1h<br>RO | **Power On Device (POD):** The SATA controller does not support cold presence detect. |
| 1 | 0h<br>RW | **Spin-Up Device (SUD):** This bit is read/write for HBAs that support staggered spin-up via CAP.SSS. This bit is read only 1 for HBAs that do not support staggered spin-up. On an edge detect from 0 to 1, the HBA shall start a COMRESET initialization sequence to the device. Clearing this bit causes no action on the interface. Clearing this bit to0 does not cause any OOB signal to be sent on the interface. When this bit is cleared to 0 and PxSCTL.DET = 0h, the HBA will enter listen mode. |
| 0 | 0h<br>RW | **Start (ST):** When set, the HBA may process the command list. When cleared, the HBA may not process the command list. Whenever this bit is changed from a 0 to a 1, the HBA starts processing the command list at entry 0. Whenever this bit is changed from a 1 to a 0, the PxCI and PxSACT register is cleared by the HBA upon the HBA putting the controller into an idle state. PxTFD shall be updated also. |

| Bit Range | Default & Access | Description |
|---|---|---|
| 31:16 | 0000h RW/1C | **Diagnostics (DIAG):** Contains diagnostic error information for use by diagnostic software in validating correct operation or isolating failure modes. Bit Field 31:27 Reserved 26 Exchanged (X): When set to one this bit indicates that a change in device presence has been detected since the last time this bit was cleared. The means by which the implementation determines that the device presence has changed is vendor specific. This bit shall always be set to one anytime a COMINIT signal is received. This bit is reflected in the P0IS.PCS bit. 25 Unrecognized FIS Type (F): Indicates that one or more FISs were received by the Transport layer with good CRC, but had a type field that was not recognized. 24 Transport state transition error (T): Indicates that an error has occurred in the transition from one state to another within the Transport layer since the last time this bit was cleared. 23 Link Sequence Error (S): Indicates that one or more Link state machine error conditions were encountered. The Link Layer state machine defines the conditions under which the link layer detects an erroneous transition. 22 Handshake Error (H): Indicates that one or more R_ERR handshake response was received in response to frame transmission. Such errors may be the result of a CRC error detected by the recipient, a disparity or 8b/10b decoding error, or other error condition leading to a negative handshake on a transmitted frame. 21 CRC Error (C): Indicates that one or more CRC errors occurred with the Link Layer. 20 Disparity Error (D): This field is not used by AHCI. 19 10B to 8B Decode Error (B): Indicates that one or more 10B to 8B decoding errors occurred. 18 Comm Wake (W): Indicates that a Comm Wake signal was detected by the Phy. 17 Phy Internal Error (I): Indicates that the Phy detected some internal error. 16 PhyRdy Change (N): When set to 1 this bit indicates that the internal PhyRdy signal changed state since the last time this bit was cleared. The state of this bit is reflected in the PxIS.PRCS interrupt status bit and an interrupt will be generated if enabled. |
| 15:0 | 0000h RW/1C | **Error (ERR):** The ERR field contains error information for use by host software in determining the appropriate response to the error condition. Persistent communications errors may arise from faulty interconnect with the device, from a device that has been removed or has failed, or a number of other causes. 8 Transient Data Integrity Error (T): A data integrity error occurred that was not recovered by the interface. 7:2 Reserved 1 Recovered Communications Error (M): Communications between the device and host was temporarily lost but was re-established. This can arise from a device temporarily being removed, from a temporary loss of Phy synchronization, or from other causes and may be derived from the PhyNRdy signal between the Phy and Link layers. 0 Recovered Data Integrity Error (I): A data integrity error occurred that was recovered by the interface through a retry operation or other recovery action. |

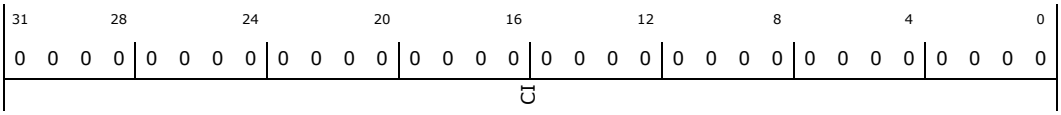
**ABAR Type:** PCI Configuration Register (Size: 32 bits)
**ABAR Reference:** [B:0, D:19, F:0] + 24h

**Default:** 00000000h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31:0 | 00000000h RW/1S | **Device Status (DS):** System software sets this bit for native command queuing commands prior to setting the PxCI.CI bit in the same command slot entry. This field is cleared via the Set Device Bits FIS. |

## 17.8.40 Port-Commands Issued (PxCI1)—Offset 1B8h



### Access Method

**Type:** Memory Mapped I/O Register (Size: 32 bits)

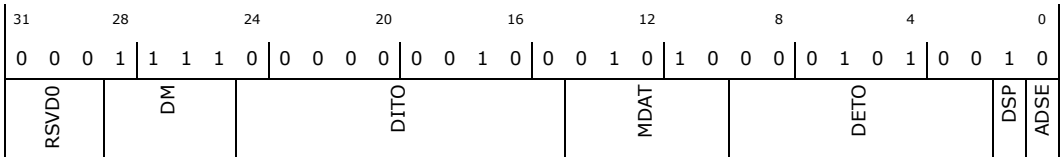
**PxCI1:** [ABAR] + 1B8h

**ABAR Type:** PCI Configuration Register (Size: 32 bits)
**ABAR Reference:** [B:0, D:19, F:0] + 24h

**Default:** 00000000h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31:0 | 00000000h RW | **Commands Issued (CI):** This field is set by software to indicate to the HBA that a command has been built in system memory for a command slot and may be sent to the device. When the HBA receives a FIS which clears the BSY, ERR, and DRQ bits for the command, it clears the corresponding bit in this register for that command slot. Bits in this field shall only be set to 1 by software when PxCMD.ST is set to 1. |

## 17.8.41 Port-Device Sleep (PxDEVSLP1)—Offset 1C4h



### Access Method

**Type:** Memory Mapped I/O Register (Size: 32 bits)

**PxDEVSLP1:** [ABAR] + 1C4h

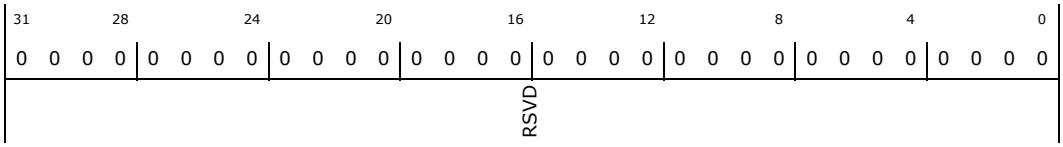
**ABAR Type:** PCI Configuration Register (Size: 32 bits)
**ABAR Reference:** [B:0, D:19, F:0] + 24h

**Default:** 1E022852h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31:29 | 0b<br>RO | **RSVD0:** Reserved |
| 28:25 | Fh<br>RW/O | **DITO Multiplier (DM):** 0's based value that specifies the DITO multiplier that the HBA applies to the specified DITO value, effectively extending the range of DITO from 1ms to 16368ms. A value of 0h indicates a multiplier of 1. A maximum multiplier of 16 may be applied. The HBA computes the total idle timeout as a product of DM and DITO (i.e. DITO actual = DITO * DM). |
| 24:15 | 004h<br>RW | **DEVSLP Idle Timeout (DITO):** This field specifies the amount of the time (in approximate 1ms granularity) that the HBA shall wait before driving the DEVSLP signal. |
| 14:10 | 0Ah<br>RW | **DEVSLP Minimum Assertion Time (MDAT):** This field specifies the minimum amount of time (in 1ms granularity) that the HBA must assert the DEVSLP signal before it may be de-asserted. The nominal value is 10ms and the minimum is 1ms depending on device identification information. |
| 9:2 | 14h<br>RW | **DEVSLP Exit Timeout (DETO):** This field specifies the maximum duration (in approximate 1ms granularity) from DEVSLP de-assertion until the device is ready to accept OOB. The nominal value is 20ms while the max value is 255ms depending on device identification information. |
| 1 | 1h<br>RW/O | **DEVSLP Present (DSP):** If set to 1, the platform supports DEVSLP on this port. If cleared to 0, the platform does not support DEVSLP on this port. |
| 0 | 0h<br>RW | **Aggressive DEVSLP Enable (ADSE):** When this bit is cleared to 0, the HBA does not enter DEVSLP unless software directed via PxCMD.ICC. This bit shall only be set to 1 if PxDEVSLP.DSP is set to 1. If this bit is set to 1 and software clears the bit to 0, then the HBA shall de-assert the DEVSLP signal if asserted. |

## 17.8.42 Enclosure Management Message Format (EM_MF)—Offset 580h

This register is not implemented in VLV.



### Access Method

**Type:** Memory Mapped I/O Register (Size: 32 bits)

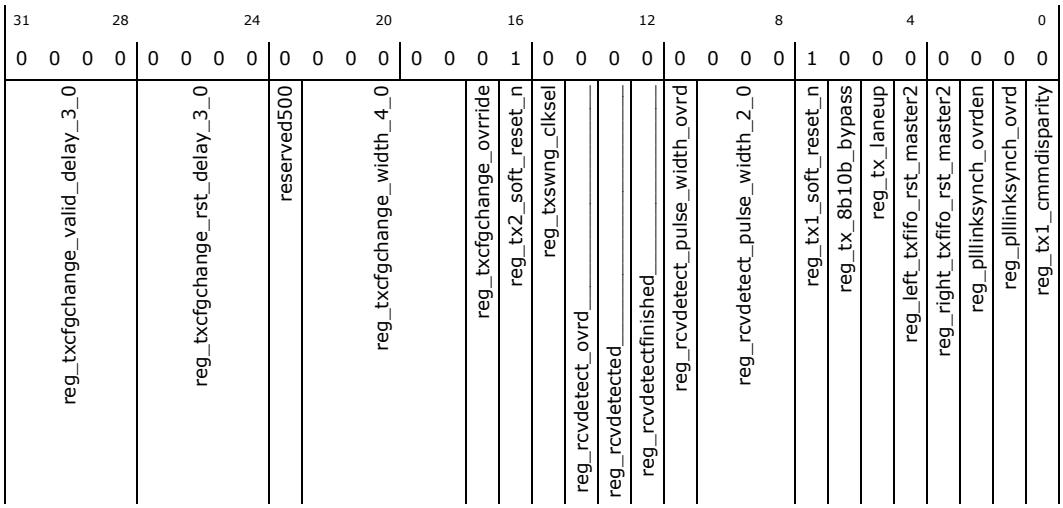
## 17.17.1 PCS_DWORD0 (pcs_dword0)—Offset 0h

### Access Method



**Type:** Message Bus Register (Size: 32 bits)

**pcs_dword0:** [Port: 0xA3] + (2200h + 0h)

**Op Codes:**

0h - Read, 1h - Write

**Default:** 00010080h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31:28 | 0h<br>RW | **reg_txcfgchange_valid_delay_3_0:** Controls counter to wait 128ns after txcfgchange asserts when coming out of reset. This will control phystatus de-assertion after reset. Note: Minimum value when programmed has to be 4'b0100 or greater. |
| 27:24 | 0h<br>RW | **reg_txcfgchange_rst_delay_3_0:** Counter value to delay txcfgchange toggle after coming out of reset. |
| 23 | 0h<br>RW | **reserved500:** reserved |
| 22:18 | 0h<br>RW | **reg_txcfgchange_width_4_0:** Tx power fsm output - divider ratio |
| 17 | 0h<br>RW | **reg_txcfgchange_ovrride:** Override txchfchange related counters. (reg_txcfgchange_width, reg_txcfgchange_valid_delay, reg_txcfgchange_rst_delay) |
| 16 | 1h<br>RW | **reg_tx2_soft_reset_n:** Active low reset to independently reset Tx lane2 in Display Port |
| 15 | 0h<br>RW | **reg_txswng_clksel:** When 0 selects divide by 2 version of the ick_plllink clock for Tx swing control logic When 1 selects ick_plllink clock for Tx swing control logic. |
| 14 | 0h<br>RW | **reg_rcvdetect_ovrd_____:** override enable for rcvdetected and rcvdetectfinished |

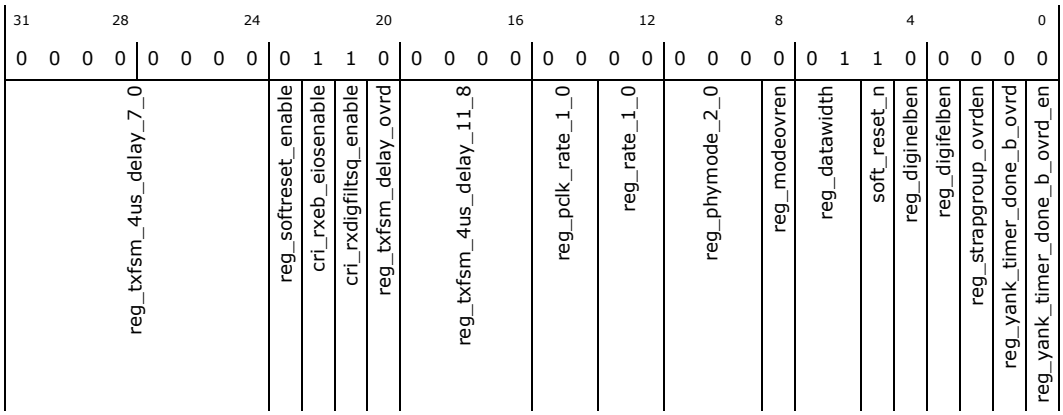
| Bit Range | Default & Access | Description |
|---|---|---|
| 11 | 0h<br>RW | **reg_rcvdetect_pulse_width_ovrd:** override enable for rcvdetect_pulse_width |
| 10:8 | 0h<br>RW | **reg_rcvdetect_pulse_width_2_0:** override value for rcvdetect_pusle_width |
| 7 | 1h<br>RW | **reg_tx1_soft_reset_n:** Active low reset to independently reset Tx lane1 in Display Port 0: Lane 1 reset 1: Lane 1 active |
| 6 | 0h<br>RW | **reg_tx_8b10b_bypass:** Bypass 8b10b encoder ( for SAPIS etc interface.) 0 = Disable 8b/10b encoder bypass 1 = Enable 8b/10b encoder bypass |
| 5 | 0h<br>RW | **reg_tx_laneup:** Unused in Tx |
| 4 | 0h<br>RW | **reg_left_txfifo_rst_master2:** override enable = reg_lanedeskew_strap_ovrd |
| 3 | 0h<br>RW | **reg_right_txfifo_rst_master2:** override enable = reg_lanedeskew_strap_ovrd |
| 2 | 0h<br>RW | **reg_plllinksynch_ovrden:** Override enable for reg_plllinsync_ovrd 0 = Use default delay in hardware 1 = Use reg_plllinksynch_ovrd |
| 1 | 0h<br>RW | **reg_plllinksynch_ovrd:** override value for plllinksynch |
| 0 | 0h<br>RW | **reg_tx1_cmmdisparity:** Sets the initial disparity during Compliance Measurement Mode, used together with pcs_txcompliance pulse. 0 = set negative disparity 1 = set positive disparity |

## 17.17.2 PCS_DWORD1 (pcs_dword1)—Offset 4h

### Access Method



**Type:** Message Bus Register (Size: 32 bits)

**pcs_dword1:** [Port: 0xA3] + (2200h + 4h)

**Op Codes:**

0h - Read, 1h - Write

**Default:** 00600060h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31:24 | 0h RW | **reg_txfsm_4us_delay_7_0:** Override counter value for 4 us delay in txfsm lane reset to txbiasen delay |
| 23 | 0h RW | **reg_softreset_enable:** When '1' the soft_reset_n bit will contol the lane reset When '0' the hardware reset will control the lane reset Note for DP: In addition to soft_reset_n,which will reset both TX0 and TX 1 in the lane, the reg_tx1_soft_reset_n bit can be used to reset only TX1 in the lane and reg_tx2_soft_reset_n bit can be used to reset only TX2 |
| 22 | 1h RW | **cri_rxeb_eiosenable:** When 1 enables EIOS based Rx power down |
| 21 | 1h RW | **cri_rxdigfiltsq_enable:** When 1 enables unsquelch based Rx power up in P0 or P0s |
| 20 | 0h RW | **reg_txfsm_delay_ovrd:** Override enable bit for reg_txfsm_4us_delay |
| 19:16 | 0h RW | **reg_txfsm_4us_delay_11_8:** Override counter value for 4 us delay in txfsm lane reset to txbiasen delay |
| 15:14 | 0h RW | **reg_pclk_rate_1_0:** Override for pclk_rate 00 = gen1 01 = gen2 10 = gen3 11 = GbE |
| 13:12 | 0h RW | **reg_rate_1_0:** Override for i_rate 00 = gen1 01 = gen2 10 = gen3 11 = GbE |

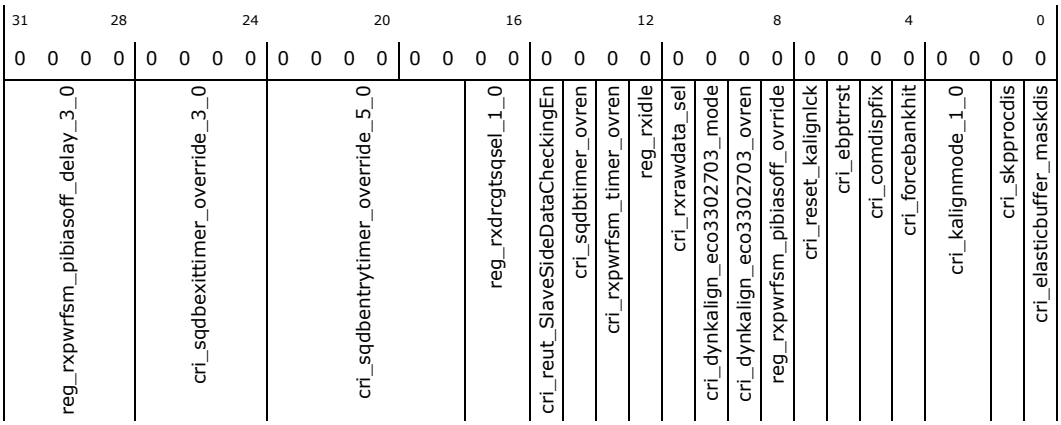
| 8 | 0h RW | **reg_modeovren:** When asserted selects register override bits for phymode, datawidth etc |
| 7:6 | 1h RW | **reg_datawidth:** Override for Tx data interface width. 00 - Unused 01 - x8/x10 width (default ) 10 - x16/x20 width 11 - x32/x40 width |

| Bit Range | Default & Access | Description |
|---|---|---|
| 5 | 1h<br>RW | **soft_reset_n:** Active low soft reset override |
| 4 | 0h<br>RW | **reg_diginelben:** Override for near end digital loopback. |
| 3 | 0h<br>RW | **reg_digifelben:** Override for far end digital loopback |
| 2 | 0h<br>RW | **reg_strapgroup_ovrden:** Override Enable for Strap Group |
| 1 | 0h<br>RW | **reg_yank_timer_done_b_ovrd:** Override for yank_timer_done_b |
| 0 | 0h<br>RW | **reg_yank_timer_done_b_ovrd_en:** Override Enable for yank_timer_done_b |

## 17.17.3 PCS_DWORD2 (pcs_dword2)—Offset 8h



### Access Method

**Type:** Message Bus Register (Size: 32 bits)

**pcs_dword2:** [Port: 0xA3] + (2200h + 8h)

**Op Codes:**
0h - Read, 1h - Write

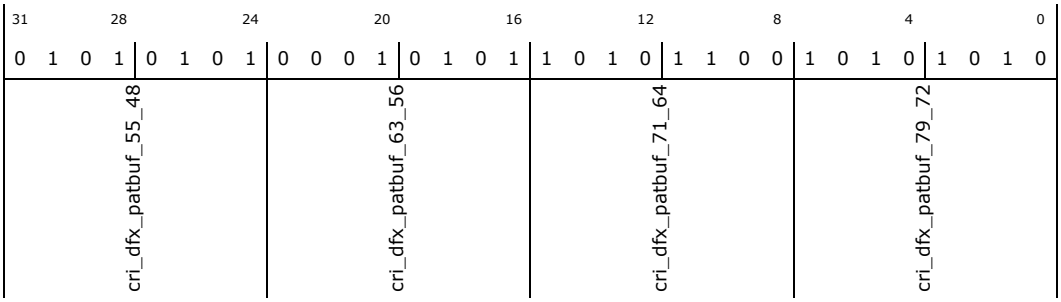
### Default: 00000000h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31:28 | 0h<br>RW | **reg_rxpwrfsm_pibiasoff_delay_3_0:** Override value for delay (in 2ns increments) between deassertion of opianclkbufen and opibiasen |
| 27:24 | 0h<br>RW | **cri_sqdbexittimer_override_3_0:** Rx squelch exit debounce timer |
| 23:18 | 0h<br>RW | **cri_sqdbentrytimer_override_5_0:** Rx squelch entry debounce timer |
| 17:16 | 0h<br>RW | **reg_rxdrcgtsqsel_1_0:** Squelch output select |

| Bit Range | Default & Access | Description |
|---|---|---|
| 15 | 0h<br>RW | **cri_reut_SlaveSideDataCheckingEn:** Enable REUT slave side checking while in loopback slave |
| 14 | 0h<br>RW | **cri_sqdbtimer_ovren:** Squelch debounce timer override enable |
| 13 | 0h<br>RW | **cri_rxpwrfsm_timer_ovren:** Rx power management fsm timer override enable |
| 12 | 0h<br>RW | **reg_rxidle:** Chicken bit to override i_rxidle from controller and keep Rx in P0 or P0s |
| 11 | 0h<br>RW | **cri_rxrawdata_sel:** When asserted bypass K-align, 10b/8b decoder and Elastic buffer |
| 10 | 0h<br>RW | **cri_dynkalign_eco3302703_mode:** Kalign Mode Override Value When cri_dynkalign_eco3302703_ovren is set, this value selects kalignmode 0 - use register bits cri_kalignmode[1:0] to select kalignmode 1 - select the 4 COM kalign mode' |
| 9 | 0h<br>RW | **cri_dynkalign_eco3302703_ovren:** Kalign Mode Override Enable Overrides kalign mode select pin, allowing config bit kalignmode_override_val to select kalignmode. |
| 8 | 0h<br>RW | **reg_rxpwrfsm_pibiasoff_ovrride:** When asserted selects reg_rxpwrfsm_pibiasoff_delay[3:0] |
| 7 | 0h<br>RW | **cri_reset_kalignlck:** When asserted resets Kalign lock indication and Kalign is performed again. The conditions when this would assert includes and is not restricted to any power management states (L0s, L1) or polling quiet states etc. |
| 6 | 0h<br>RW | **cri_ebptrrst:** Global broadcast to all lanes that the Elastic Buffer pointers should be reset. This is a pulse and will be generated when we need to reset the pointers because of collision or various other reasons. |
| 5 | 0h<br>RW | **cri_comdispfix:** Chicken bit to force disparity in dynamic K-align mode |
| 4 | 0h<br>RW | **cri_forcebankhit:** Chicken bit to enable data appear on NOA post k-align lock although k-align block is not achieving lock. This is only for NOA observeability and not for other purpose |
| 3:2 | 0h<br>RW | **cri_kalignmode_1_0:** KALIGN Mode Select 00 = dynamic kalign all the time. Accounts for bit slips on incoming stream which can cause symbol to be detected on different bank 10 = dynamic kalign up to L0 x1 = static kalign (same as GDG). Assumes symbol always detected on same data bank |
| 1 | 0h<br>RW | **cri_skpprocdis:** SKIP Ordered-Set Processing Disable When this configuration bit is asserted, then SKIP ordered=sets will be ignored (in EB block). Used in Elastic buffer block. 0 = Normal operation. SKIP ordered=sets will be processed by the Elastic Buffer 1 = SKIP processing disabled. |
| 0 | 0h<br>RW | **cri_elasticbuffer_maskdis:** Config bit (chicken bit) to disable the masking logic after elec idle ordered set is seen |

## 17.17.4 PCS_DWORD3 (pcs_dword3)—Offset Ch

### Access Method



**Type:** Message Bus Register (Size: 32 bits)

**pcs_dword3:** [Port: 0xA3] + (2200h + Ch)

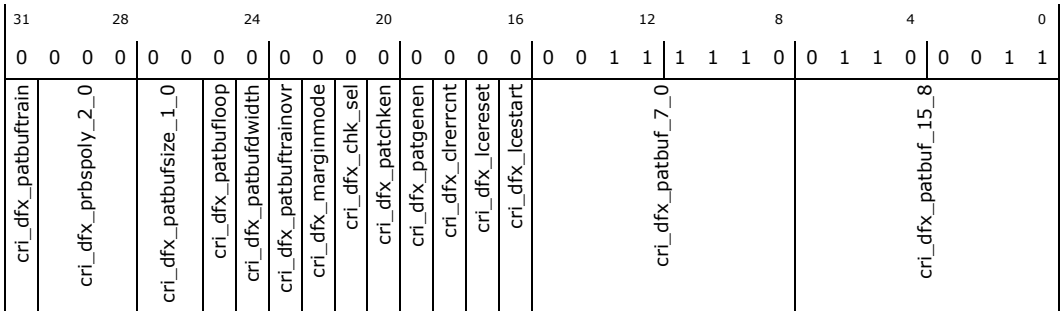
## 17.17.6 PCS_DWORD5 (pcs_dword5)—Offset 14h

### Access Method



**Type:** Message Bus Register (Size: 32 bits)

**pcs_dword5:** [Port: 0xA3] + (2200h + 14h)

**Op Codes:**

0h - Read, 1h - Write

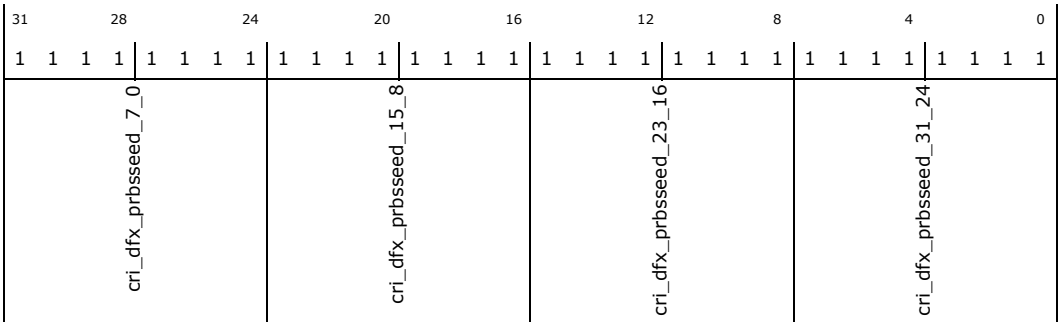
**Default:** 00003E63h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31 | 0h<br>RW | **cri_dfx_patbuftrain:** Pattern Buffer Manual Training When DFXPATBUFTRAINOVR and DFXLCESTART are asserted, this manually controls whether the Pattern Buffers are in training or have completed training. 0 : Send training patterns (default) 1 : Send contents of DFXPATBUF |
| 30:28 | 0h<br>RW | **cri_dfx_prbspoly_2_0:** PRBS Polynomial Select the polynomial to be used by the PRBS in the Pattern Generator and Pattern Checker. PRBS support 10b or 8b, which is indicated by the msb. 000 - x^16 + x^5 + x^4 + x^3 + 1 (USB3/PCIe Scrambler) (8b) 001 - x^16 + x^15 + x^13 + x^4 + 1 (SATA scrambler) (8b) 010 - x^31 + x^28 + 1 (8b) 011 - x^7 + x^6 + 1 (8b) 100 - x^15 + x^14 + 1 (10b) 101 - x^23 + x^18 + 1 (10b) 110 - x^31 + x^28 + 1 (10b) 111 - x^7 + x^6 + 1 (10b) |
| 27:26 | 0h<br>RW | **cri_dfx_patbufsize_1_0:** Pattern Buffer Size Select the size of the Pattern Buffer to use. The MSB will always be bit 79. The LSB will depend on this select and the DFXLCEDATAWIDTH (10b or 8b mode). 00 : full 80b buffer (Default) 01 : 70b (while in 10b mode), 56b (while in 8b mode) 10 : 40b (while in 10b mode), 32b (while in 8b mode) 11 : 10b (while in 10b mode), 8b (while in 8b mode) |
| 25 | 0h<br>RW | **cri_dfx_patbufloop:** Pattern Buffer Looping Enable Enables looping of the Patter Buffer. By default, the contents of Pattern Buffer will be used once and stop. Alternatively, the Pattern Buffer will continue to loop until the DFXLCESTART is de-asserted. 0 : Run Pattern Buffer only once (default) 1 : Loop Pattern Buffer until stopped |
| 24 | 0h<br>RW | **cri_dfx_patbufdwidth:** Pattern Buffer Data Width Selects between 10 bit or 8 bit data width for the Pattern Buffer. Determines where in the Tx/Rx path the data is inserted/ retrieved. 0 : 10b (default) 1 : 8b |
| 23 | 0h<br>RW | **cri_dfx_patbuftrainovr:** Pattern Buffer Training Override Enables manual training of the Pattern Buffer instead of the automated coordination between the Pattern Checker and Patter Generator. When asserted, the DFXPATBUFTRAIN bit will be used to force when training is active and when it is complete. 0 : Automatic Training (default) 1 : Enable Manual Training |

| Bit Range | Default & Access | Description |
|---|---|---|
| 22 | 0h<br>RW | **cri_dfx_marginmode:** Margin mode Overrides standard setup configurations for use with Eye Width Margining. 0 : Standard Mode (default) 1 : Margin Mode enabled |
| 21 | 0h<br>RW | **cri_dfx_chk_sel:** Pattern Checker 8b10b Select This determines where Rx data is compared, either in the 10-bit domain before decode or after 10b-)8b decoding. 0: 10b domain 1: 8b domain |
| 20 | 0h<br>RW | **cri_dfx_patchken:** Pattern Checker Enable 0 : Disable Pattern Checker (default) 1 : Enable Pattern Checker |
| 19 | 0h<br>RW | **cri_dfx_patgenen:** Pattern Generator Enable This will activate the DFx bypass muxes in the PCS Tx path. 0 : Disable Pattern Generator (default) 1 : Enable Pattern Generator |
| 18 | 0h<br>RW | **cri_dfx_clrerrcnt:** Clear Error Counter Resets the Pattern Checker's error counter. 0 : Error Counter allowed to run (default) 1 : Error Counter held in reset |
| 17 | 0h<br>RW | **cri_dfx_lcereset:** Local Compare Engine Reset Resets all components of the Local Compare Engine in both the Pattern Generator and the Pattern Checker. 0 : LCE not in reset (default) 1 : LCE in reset |
| 16 | 0h<br>RW | **cri_dfx_lcestart:** Local Compare Engine Start Controls the starting and stopping of the LCE. Allows for simultaneous or independent start across lanes. Once stopped, a DFXLCERESET is usually required. 0 : LCE stopped (default) 1 : LCE running |
| 15:8 | 3Eh<br>RW | **cri_dfx_patbuf_7_0:** Pattern Buffer Storage In 10b mode, the buffer is read as eight 10b chunks. The first 10 bits should not equal the Comma Symbol: '0011111010' (or its inversion '1100000101'). In 8b mode, the buffer is read as eight 10b chunks, where the 10th bit is unused and the 9th bit is the K-bit indicator. The first 10 bits should not equal the Comma Symbol: 'xx10111100'. DFXPATBUF[78] should not = '1'. |
| 7:0 | 63h<br>RW | **cri_dfx_patbuf_15_8:** Pattern Buffer Storage See cri_dfx_patbuf[7:0] description. |

## 17.17.7 PCS_DWORD6 (pcs_dword6)—Offset 18h

### Access Method



**Type:** Message Bus Register (Size: 32 bits)

**pcs_dword6:** [Port: 0xA3] + (2200h + 18h)

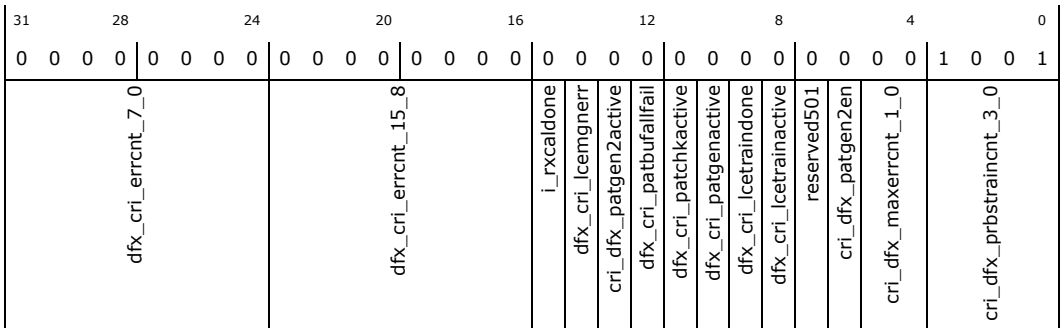
## 17.17.8 PCS_DWORD7 (pcs_dword7)—Offset 1Ch

### Access Method



**Type:** Message Bus Register (Size: 32 bits)

**pcs_dword7:** [Port: 0xA3] + (2200h + 1Ch)

**Op Codes:**

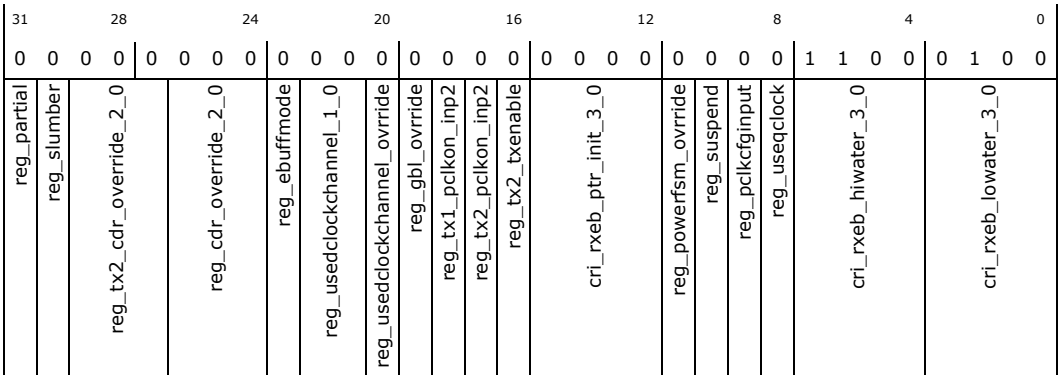
0h - Read, 1h - Write

**Default:** 00000009h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31:24 | X<br>RO | **dfx_cri_errcnt_7_0:** Error Counter Tracks how many bit errors the Pattern Checker has detected. Can be cleared using DFXCLRERRCNT or DFXLCERESET. |
| 23:16 | X<br>RO | **dfx_cri_errcnt_15_8:** Error Counter Tracks how many bit errors the Pattern Checker has detected. Can be cleared using DFXCLRERRCNT or DFXLCERESET. |
| 15 | X<br>RO | **i_rxcaldone:** RX Calibration Cycles Complete Indicator |
| 14 | X<br>RO | **dfx_cri_lcemgnerr:** Local Compare Engine Margin Error Indicates that the error counter has reached its max value. This can be used by the Rx upartition during Margin Mode to determine when the eye width has closed. |
| 13 | X<br>RO | **cri_dfx_patgen2active:** Pattern Generator 2 Active status indicator In a lane with two Tx paths, this indicates that the second Pattern Generator is in progress. The DFXPATGENACTIVE will only indicate that the first Pattern Generator is in progress. |
| 12 | X<br>RO | **dfx_cri_patbufallfail:** Pattern Buffer All Fail status indicator Indicates that there has not been a single matching Pattern Buffer pattern. This could signify that an error occured during training. |
| 11 | X<br>RO | **dfx_cri_patchkactive:** Pattern Checker Active status indicator Indicates that the Pattern Checker is in progress (either Pattern Buffer or PRBS). |
| 10 | X<br>RO | **dfx_cri_patgenactive:** Pattern Generator Active status indicator Indicates that the Pattern Generator is in progress (either Pattern Buffer or PRBS). |

| Bit Range | Default & Access | Description |
|---|---|---|
| 9 | X<br>RO | **dfx_cri_lcetraindone:** Local Compare Engine Training Done status indicator Indicates that the Pattern Checker training is completed (either Pattern Buffer or PRBS). The Pattern Checker is now synchronized to the Pattern Generator. |
| 8 | X<br>RO | **dfx_cri_lcetrainactive:** Local Compare Engine Training Active status indicator Indicates that the Pattern Checker training is in progress (either Pattern Buffer or PRBS). |
| 7 | 0h<br>RW | **reserved501:** reserved |
| 6 | 0h<br>RW | **cri_dfx_patgen2en:** Pattern Generator 2 Enable In a lane with two Tx paths, this enables the second Pattern Generator. The DFXPATGENEN will enable the first Pattern Generator. 0 : Disable second Pattern Generator (default) 1 : Enable second Pattern Generator |
| 5:4 | 0h<br>RW | **cri_dfx_maxerrcnt_1_0:** Maximum Error Count Selectable maximum value that the DFXERRCNT can reach before the Local Compare Engine is automatically stopped. 00 : 2^16 (default) 01 : 2^10 10 : 2^8 11 : 2^4 |
| 3:0 | 9h<br>RW | **cri_dfx_prbstraincnt_3_0:** PRBS Training Count The number of consecutive cycles that the Pattern Checker's PRBS must be error free before it is considered synchronized. Default is 9. |

## 17.17.9 PCS_DWORD8 (pcs_dword8)—Offset 20h



### Access Method

**Type:** Message Bus Register (Size: 32 bits)

**pcs_dword8:** [Port: 0xA3] + (2200h + 20h)

**Op Codes:**
0h - Read, 1h - Write

**Default:** 000000C4h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31 | 0h<br>RW | **reg_partial:** Override for i_partial |
| 30 | 0h<br>RW | **reg_slumber:** Override for i_slumber |
| 29:27 | 0h<br>RW | **reg_tx2_cdr_override_2_0:** Override for cdr_override strap for second tx2 |

| Bit Range | Default & Access | Description |
|---|---|---|
| 26:24 | 0h<br>RW | **reg_cdr_override_2_0:** Override for cdr_override strap |
| 23 | 0h<br>RW | **reg_ebuffmode:** Override for ebuffmode (no functionality in p1271 phase1 design) |
| 22:21 | 0h<br>RW | **reg_usedclockchannel_1_0:** Selects the active clock channel |
| 20 | 0h<br>RW | **reg_usedclockchannel_ovrride:** When asserted selects reg_usedclockchannel[1:0] |
| 19 | 0h<br>RW | **reg_gbl_ovrride:** Global override select |
| 18 | 0h<br>RW | **reg_tx1_pclkon_inp2:** When asserted keeps PCLK running in P2 mode. For DP this is used for Lane1 |

| Bit Range | Default & Access | Description |
|---|---|---|
| 25 | 0h<br>RW | **i_rxsq_asyncmode_h:** Squelch Async Startup Mode This squelch startup mode is power state independent. When enabled, the squelchen signal sent to Modphy will asynchronously enable the squelch detector circuit. Once enabled, the squelch detector circuit will asynchronously send an unfiltered/unqualified squelch indication signal out of Modphy. The squelch indication signal will initially be unstable, so it is up to the consumer of this signal to filter/qualfiy it accordingly. The asynchronous squelch startup mode is beneficial because it significantly reduces the squelch startup latency. This decrease in latency does come at the cost of slightly higher power when squelch is not enabled as the IREF and Squelch Keeper circuits must remain enabled. When disabled, the squelch startup sequence is synchronous in nature and the squelch indication signal sent out of Modphy is stable/filtered. |

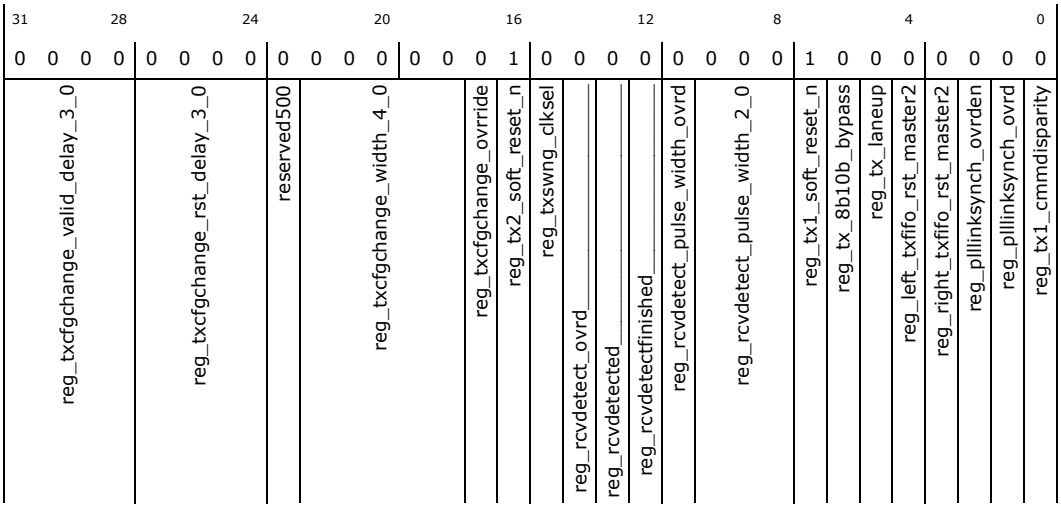
### 17.19.1 PCS_DWORD0 (pcs_dword0)—Offset 0h

#### Access Method



**Type:** Message Bus Register (Size: 32 bits)

**pcs_dword0:** [Port: 0xA3] + (2400h + 0h)

**Op Codes:**

0h - Read, 1h - Write

**Default:** 00010080h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31:28 | 0h<br>RW | **reg_txcfgchange_valid_delay_3_0:** Controls counter to wait 128ns after txcfgchange asserts when coming out of reset. This will control phystatus de-assertion after reset. Note: Minimum value when programmed has to be 4'b0100 or greater. |
| 27:24 | 0h<br>RW | **reg_txcfgchange_rst_delay_3_0:** Counter value to delay txcfgchange toggle after coming out of reset. |
| 23 | 0h<br>RW | **reserved500:** reserved |
| 22:18 | 0h<br>RW | **reg_txcfgchange_width_4_0:** Tx power fsm output - divider ratio |
| 17 | 0h<br>RW | **reg_txcfgchange_ovrride:** Override txchfchange related counters. (reg_txcfgchange_width, reg_txcfgchange_valid_delay, reg_txcfgchange_rst_delay) |
| 16 | 1h<br>RW | **reg_tx2_soft_reset_n:** Active low reset to independently reset Tx lane2 in Display Port |
| 15 | 0h<br>RW | **reg_txswng_clksel:** When 0 selects divide by 2 version of the ick_plllink clock for Tx swing control logic When 1 selects ick_plllink clock for Tx swing control logic. |
| 14 | 0h<br>RW | **reg_rcvdetect_ovrd_____:** override enable for rcvdetected and rcvdetectfinished |

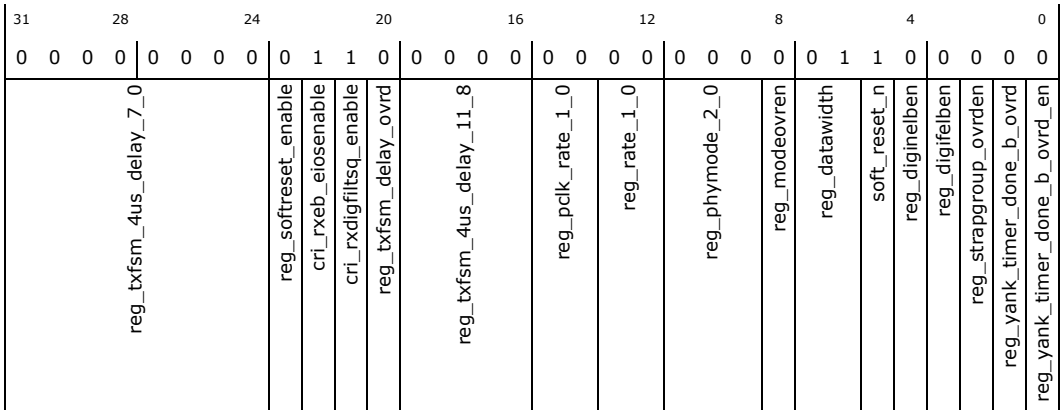
| 10:8 | 0h<br>RW | **reg_rcvdetect_pulse_width_2_0:** override value for rcvdetect_pusle_width |
| 7 | 1h<br>RW | **reg_tx1_soft_reset_n:** Active low reset to independently reset Tx lane1 in Display Port 0: Lane 1 reset 1: Lane 1 active |
| 6 | 0h<br>RW | **reg_tx_8b10b_bypass:** Bypass 8b10b encoder ( for SAPIS etc interface.) 0 = Disable 8b/10b encoder bypass 1 = Enable 8b/10b encoder bypass |

| Bit Range | Default & Access | Description |
|---|---|---|
| 5 | 0h<br>RW | **reg_tx_laneup:** Unused in Tx |
| 4 | 0h<br>RW | **reg_left_txfifo_rst_master2:** override enable = reg_lanedeskew_strap_ovrd |
| 3 | 0h<br>RW | **reg_right_txfifo_rst_master2:** override enable = reg_lanedeskew_strap_ovrd |
| 2 | 0h<br>RW | **reg_plllinksynch_ovrden:** Override enable for reg_plllinsync_ovrd 0 = Use default delay in hardware 1 = Use reg_plllinksynch_ovrd |
| 1 | 0h<br>RW | **reg_plllinksynch_ovrd:** override value for plllinksynch |
| 0 | 0h<br>RW | **reg_tx1_cmmdisparity:** Sets the initial disparity during Compliance Measurement Mode, used together with pcs_txcompliance pulse. 0 = set negative disparity 1 = set positive disparity |

## 17.19.2 PCS_DWORD1 (pcs_dword1)—Offset 4h

### Access Method



**Type:** Message Bus Register (Size: 32 bits)

**pcs_dword1:** [Port: 0xA3] + (2400h + 4h)

**Op Codes:**

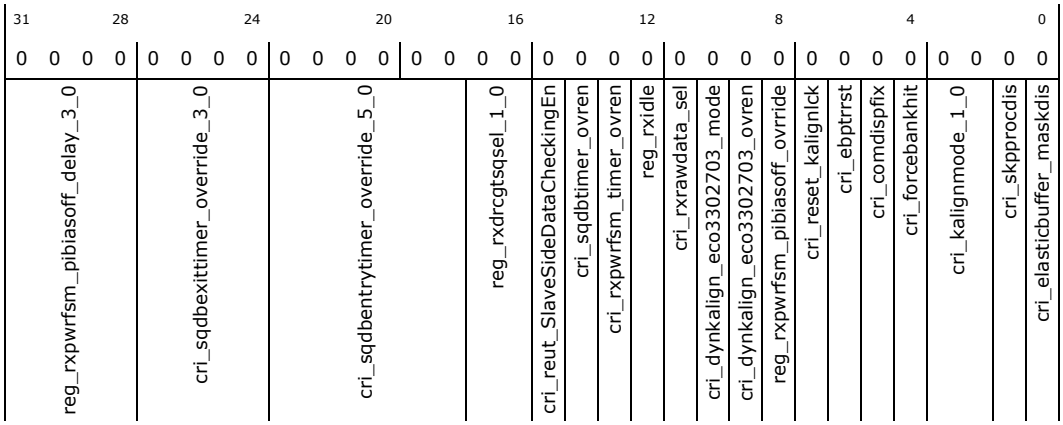
0h - Read, 1h - Write

**Default:** 00600060h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31:24 | 0h<br>RW | **reg_txfsm_4us_delay_7_0:** Override counter value for 4 us delay in txfsm lane reset to txbiasen delay |
| 23 | 0h<br>RW | **reg_softreset_enable:** When '1' the soft_reset_n bit will contol the lane reset When '0' the hardware reset will control the lane reset Note for DP: In addition to soft_reset_n,which will reset both TX0 and TX 1 in the lane, the reg_tx1_soft_reset_n bit can be used to reset only TX1 in the lane and reg_tx2_soft_reset_n bit can be used to reset only TX2 |
| 22 | 1h<br>RW | **cri_rxeb_eiosenable:** When 1 enables EIOS based Rx power down |

| Bit Range | Default & Access | Description |
|---|---|---|
| 21 | 1h RW | **cri_rxdigfiltsq_enable:** When 1 enables unsquelch based Rx power up in P0 or P0s |
| 20 | 0h RW | **reg_txfsm_delay_ovrd:** Override enable bit for reg_txfsm_4us_delay |
| 19:16 | 0h RW | **reg_txfsm_4us_delay_11_8:** Override counter value for 4 us delay in txfsm lane reset to txbiasen delay |
| 15:14 | 0h RW | **reg_pclk_rate_1_0:** Override for pclk_rate 00 = gen1 01 = gen2 10 = gen3 11 = GbE |
| 13:12 | 0h RW | **reg_rate_1_0:** Override for i_rate 00 = gen1 01 = gen2 10 = gen3 11 = GbE |
| 11:9 | 0h RW | **reg_phymode_2_0:** Override for PHY Mode Selection 000 = PCIE 001 = USB3 010 = GbE 011 = SATA/SAPIS 100 = Display 101 = DMI 110 = CIO 111 =Reserved |
| 8 | 0h RW | **reg_modeovren:** When asserted selects register override bits for phymode, datawidth etc |
| 7:6 | 1h RW | **reg_datawidth:** Override for Tx data interface width. 00 - Unused 01 - x8/x10 width (default ) 10 - x16/x20 width 11 - x32/x40 width |
| 5 | 1h RW | **soft_reset_n:** Active low soft reset override |
| 4 | 0h RW | **reg_diginelben:** Override for near end digital loopback. |
| 3 | 0h RW | **reg_digifelben:** Override for far end digital loopback |
| 2 | 0h RW | **reg_strapgroup_ovrden:** Override Enable for Strap Group |
| 1 | 0h RW | **reg_yank_timer_done_b_ovrd:** Override for yank_timer_done_b |
| 0 | 0h RW | **reg_yank_timer_done_b_ovrd_en:** Override Enable for yank_timer_done_b |

## 17.19.3 PCS_DWORD2 (pcs_dword2)—Offset 8h



### Access Method

**Type:** Message Bus Register (Size: 32 bits)

**pcs_dword2:** [Port: 0xA3] + (2400h + 8h)

**Op Codes:**
0h - Read, 1h - Write

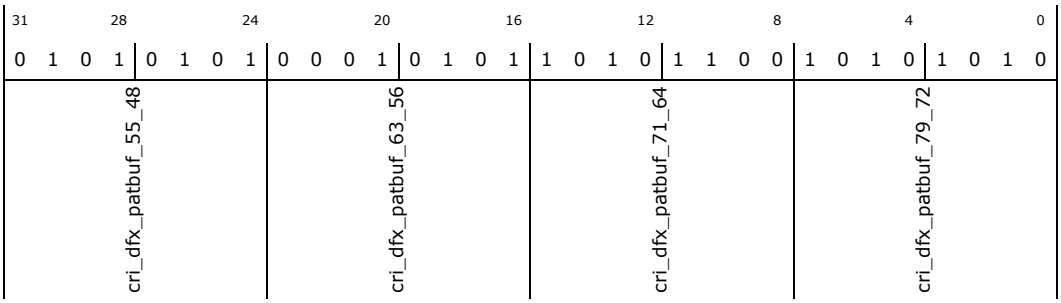
**Default:** 00000000h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31:28 | 0h<br>RW | **reg_rxpwrfsm_pibiasoff_delay_3_0:** Override value for delay (in 2ns increments) between deassertion of opianclkbufen and opibiasen |
| 27:24 | 0h<br>RW | **cri_sqdbexittimer_override_3_0:** Rx squelch exit debounce timer |
| 23:18 | 0h<br>RW | **cri_sqdbentrytimer_override_5_0:** Rx squelch entry debounce timer |
| 17:16 | 0h<br>RW | **reg_rxdrcgtsqsel_1_0:** Squelch output select |
| 15 | 0h<br>RW | **cri_reut_SlaveSideDataCheckingEn:** Enable REUT slave side checking while in loopback slave |
| 14 | 0h<br>RW | **cri_sqdbtimer_ovren:** Squelch debounce timer override enable |
| 13 | 0h<br>RW | **cri_rxpwrfsm_timer_ovren:** Rx power management fsm timer override enable |
| 12 | 0h<br>RW | **reg_rxidle:** Chicken bit to override i_rxidle from controller and keep Rx in P0 or P0s |
| 11 | 0h<br>RW | **cri_rxrawdata_sel:** When asserted bypass K-align, 10b/8b decoder and Elastic buffer |
| 10 | 0h<br>RW | **cri_dynkalign_eco3302703_mode:** Kalign Mode Override Value When cri_dynkalign_eco3302703_ovren is set, this value selects kalignmode 0 - use register bits cri_kalignmode[1:0] to select kalignmode 1 - select the 4 COM kalign mode' |
| 9 | 0h<br>RW | **cri_dynkalign_eco3302703_ovren:** Kalign Mode Override Enable Overrides kalign mode select pin, allowing config bit kalignmode_override_val to select kalignmode. |
| 8 | 0h<br>RW | **reg_rxpwrfsm_pibiasoff_ovrride:** When asserted selects reg_rxpwrfsm_pibiasoff_delay[3:0] |
| 7 | 0h<br>RW | **cri_reset_kalignlck:** When asserted resets Kalign lock indication and Kalign is performed again. The conditions when this would assert includes and is not restricted to any power management states (L0s, L1) or polling quiet states etc. |
| 6 | 0h<br>RW | **cri_ebptrrst:** Global broadcast to all lanes that the Elastic Buffer pointers should be reset. This is a pulse and will be generated when we need to reset the pointers because of collision or various other reasons. |
| 5 | 0h<br>RW | **cri_comdispfix:** Chicken bit to force disparity in dynamic K-align mode |

| Bit Range | Default & Access | Description |
|---|---|---|
| 4 | 0h<br>RW | **cri_forcebankhit:** Chicken bit to enable data appear on NOA post k-align lock although k-align block is not achieving lock. This is only for NOA observeability and not for other purpose |
| 3:2 | 0h<br>RW | **cri_kalignmode_1_0:** KALIGN Mode Select 00 = dynamic kalign all the time. Accounts for bit slips on incoming stream which can cause symbol to be detected on different bank 10 = dynamic kalign up to L0 x1 = static kalign (same as GDG). Assumes symbol always detected on same data bank |
| 1 | 0h<br>RW | **cri_skpprocdis:** SKIP Ordered-Set Processing Disable When this configuration bit is asserted, then SKIP ordered=sets will be ignored (in EB block). Used in Elastic buffer block. 0 = Normal operation. SKIP ordered=sets will be processed by the Elastic Buffer 1 = SKIP processing disabled. |
| 0 | 0h<br>RW | **cri_elasticbuffer_maskdis:** Config bit (chicken bit) to disable the masking logic after elec idle ordered set is seen |

## 17.19.4 PCS_DWORD3 (pcs_dword3)—Offset Ch

### Access Method



**Type:** Message Bus Register (Size: 32 bits)

**pcs_dword3:** [Port: 0xA3] + (2400h + Ch)

**Op Codes:**

0h - Read, 1h - Write

**Default:** 5515ACAAh

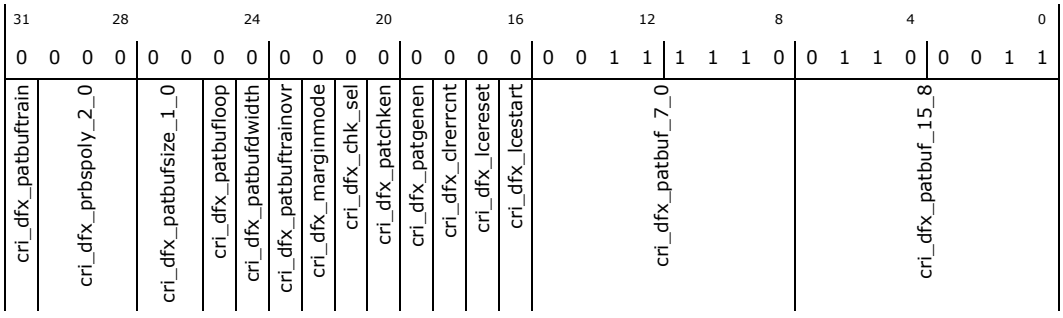
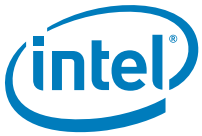
## 17.19.6 PCS_DWORD5 (pcs_dword5)—Offset 14h



### Access Method



**Type:** Message Bus Register (Size: 32 bits)

**pcs_dword5:** [Port: 0xA3] + (2400h + 14h)

**Op Codes:**
0h - Read, 1h - Write

**Default:** 00003E63h

| Bit Range | Default & Access | Description |
|---|---|---|
| 31 | 0h<br>RW | **cri_dfx_patbuftrain:** Pattern Buffer Manual Training When DFXPATBUFTRAINOVR and DFXLCESTART are asserted, this manually controls whether the Pattern Buffers are in training or have completed training. 0 : Send training patterns (default) 1 : Send contents of DFXPATBUF |
| 30:28 | 0h<br>RW | **cri_dfx_prbspoly_2_0:** PRBS Polynomial Select the polynomial to be used by the PRBS in the Pattern Generator and Pattern Checker. PRBS support 10b or 8b, which is indicated by the msb. 000 - x^16 + x^5 + x^4 + x^3 + 1 (USB3/PCIe Scrambler) (8b) 001 - x^16 + x^15 + x^13 + x^4 + 1 (SATA scrambler) (8b) 010 - x^31 + x^28 + 1 (8b) 011 - x^7 + x^6 + 1 (8b) 100 - x^15 + x^14 + 1 (10b) 101 - x^23 + x^18 + 1 (10b) 110 - x^31 + x^28 + 1 (10b) 111 - x^7 + x^6 + 1 (10b) |
| 27:26 | 0h<br>RW | **cri_dfx_patbufsize_1_0:** Pattern Buffer Size Select the size of the Pattern Buffer to use. The MSB will always be bit 79. The LSB will depend on this select and the DFXLCEDATAWIDTH (10b or 8b mode). 00 : full 80b buffer (Default) 01 : 70b (while in 10b mode), 56b (while in 8b mode) 10 : 40b (while in 10b mode), 32b (while in 8b mode) 11 : 10b (while in 10b mode), 8b (while in 8b mode) |
| 25 | 0h<br>RW | **cri_dfx_patbufloop:** Pattern Buffer Looping Enable Enables looping of the Patter Buffer. By default, the contents of Pattern Buffer will be used once and stop. Alternatively, the Pattern Buffer will continue to loop until the DFXLCESTART is de-asserted. 0 : Run Pattern Buffer only once (default) 1 : Loop Pattern Buffer until stopped |
| 24 | 0h<br>RW | **cri_dfx_patbufdwidth:** Pattern Buffer Data Width Selects between 10 bit or 8 bit data width for the Pattern Buffer. Determines where in the Tx/Rx path the data is inserted/ retrieved. 0 : 10b (default) 1 : 8b |
| 23 | 0h<br>RW | **cri_dfx_patbuftrainovr:** Pattern Buffer Training Override Enables manual training of the Pattern Buffer instead of the automated coordination between the Pattern Checker and Patter Generator. When asserted, the DFXPATBUFTRAIN bit will be used to force when training is active and when it is complete. 0 : Automatic Training (default) 1 : Enable Manual Training |
| 22 | 0h<br>RW | **cri_dfx_marginmode:** Margin mode Overrides standard setup configurations for use with Eye Width Margining. 0 : Standard Mode (default) 1 : Margin Mode enabled |
| 21 | 0h<br>RW | **cri_dfx_chk_sel:** Pattern Checker 8b10b Select This determines where Rx data is compared, either in the 10-bit domain before decode or after 10b-)8b decoding. 0: 10b domain 1: 8b domain |
| 20 | 0h<br>RW | **cri_dfx_patchken:** Pattern Checker Enable 0 : Disable Pattern Checker (default) 1 : Enable Pattern Checker |
| 19 | 0h<br>RW | **cri_dfx_patgenen:** Pattern Generator Enable This will activate the DFx bypass muxes in the PCS Tx path. 0 : Disable Pattern Generator (default) 1 : Enable Pattern Generator |
| 18 | 0h<br>RW | **cri_dfx_clrerrcnt:** Clear Error Counter Resets the Pattern Checker's error counter. 0 : Error Counter allowed to run (default) 1 : Error Counter held in reset |
| 17 | 0h<br>RW | **cri_dfx_lcereset:** Local Compare Engine Reset Resets all components of the Local Compare Engine in both the Pattern Generator and the Pattern Checker. 0 : LCE not in reset (default) 1 : LCE in reset |
| 16 | 0h<br>RW | **cri_dfx_lcestart:** Local Compare Engine Start Controls the starting and stopping of the LCE. Allows for simultaneous or independent start across lanes. Once stopped, a DFXLCERESET is usually required. 0 : LCE stopped (default) 1 : LCE running |
| 15:8 | 3Eh<br>RW | **cri_dfx_patbuf_7_0:** Pattern Buffer Storage In 10b mode, the buffer is read as eight 10b chunks. The first 10 bits should not equal the Comma Symbol: '0011111010' (or its inversion '1100000101'). | 25 | 0h<br>RW | **i_rxsq_asyncmode_h:** Squelch Async Startup Mode This squelch startup mode is power state independent. When enabled, the squelchen signal sent to Modphy will asynchronously enable the squelch detector circuit. Once enabled, the squelch detector circuit will asynchronously send an unfiltered/unqualified squelch indication signal out of Modphy. The squelch indication signal will initially be unstable, so it is up to the consumer of this signal to filter/qualfiy it accordingly. The asynchronous squelch startup mode is beneficial because it significantly reduces the squelch startup latency. This decrease in latency does come at the cost of slightly higher power when squelch is not enabled as the IREF and Squelch Keeper circuits must remain enabled. When disabled, the squelch startup sequence is synchronous in nature and the squelch indication signal sent out of Modphy is stable/filtered. |

# 18 USB Host Controller Interfaces (xHCI, EHCI)

The USB Host Controllers (xHCI, EHCI) supports:

- One (1) Super Speed (SS) port on xHCI
- Four (4) Low Speed (LS)/Full Speed (FS)/High Speed (HS) ports on xHCI or EHCI
- Two (2) High Speed (HS) High Speed Inter-Chip (HSIC) ports on xHCI

***Note:*** The SS port must share a LS/FS/HS port to have a full SS connector leaving three LS/FS/HS ports available.

***Note:*** Only one host controller (either xHCI or EHCI) can be used. To enable HSIC and SS ports, xHCI must be used.

## 18.1 Signal Descriptions

See Chapter 2, "Physical Interfaces" for additional details.

The signal description table has the following headings:

- **Signal Name:** The name of the signal/pin
- **Direction**: The buffer direction can be either input, output, or I/O (bidirectional)
- **Platform Power**: The reference power plane.
- **Description**: A brief explanation of the signal's function

### Table 209. USB 3 SS Signals

**Figure 103.xHCI and EHCI Port Mapping**

**Note:** xHCI (3.0) SS is the debug port for xHCI controller.
**Note:** EHCI (1/2.0) Port 1 is the debug port of the EHCI controller

## 18.2 USB 3.0 xHCI (Extensible Host Controller Interface)

The xHCI compliant host controller can control up to 7 USB host ports. It supports devices conforming to USB 1.x to 3.0 at bit rates up to 5 Gbps.

### 18.2.1 Features of USB 3.0 Host

The USB 3.0 Super Speed data interface is a four wire differential (TX and RX pairs) interface that supports simultaneous bi-directional data transmission. The interface supports a bit rate of 5 Gbps with a maximum theoretical data throughput over 3.2 Gbps due to 8b/10b symbol encoding scheme and protocol overhead (link flow control, packet framing and protocol overhead).

Low Frequency Periodic signaling (LFPS) is used to communicate initialization, training and power management information across a link that is in low power link state without using Super Speed signaling. This reduces power consumption.

The USB3.0 port may be paired with any USB2 port at the connector – selection of any USB2 port other than port 0 will require the appropriate mapping.Figure 103 shows the USB3 port paired with USB2 port 0.

**USB3.0 Controller Features**

- Supported by xHCI software host controller interface
- USB3 port disable
- Supports local dynamic clock gating and trunk clock gating
- Supports USB 3.0 LPM (U0, U1, U2, and U3) and also a SS Disabled low power state

- Support for USB3 Debug Device

***Note:*** Recommended not to disconnect the connection when a debug session is in progress.

### 18.2.2 Features of USB HSIC

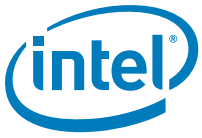
HSIC is a 2-signal (strobe and data) source synchronous serial interface for on board inter-chip USB communication. The interface uses 240 MHz DDR signaling to provide High-Speed 480 Mb/s USB transfers which are 100% host driver compatible with traditional USB cable connected topologies. Full Speed (FS) and Low Speed (LS) USB transfers are not directly supported by the HSIC interface.

For details of HSIC applications supported, Contact local Intel Sales office.

Major feature and performance highlights are as follows:

- Supported by xHCI software host controller interface
- High-Speed 480 Mb/s data rate only
- Source-synchronous serial interface
- Interface Power is only consumed when a transfer is in progress
- No hot plug removal/attach at HSIC pins
- Signals driven at 1.2V standard LVCMOS levels
- Designed for low power applications
- Support for two host ports compliant to High Speed Inter-Chip Supplement (HSIC) to the USB 2.0 Specification. (USB 2.0)

## 18.3 USB 2.0 Enhanced Host Controller Interface (EHCI)



The EHCI compliant host controller supports up to 4 USB 2.0 ports in legacy mode. USB 2.0 allows data transfers up to 480 Mbps. The controller integrates a Root Matching Hub (RMH) to support USB 1.1 devices.

***Note:*** The EHCI is not used when the xHCI is used. The EHCI is primarily present for legacy usage, in cases when xHCI support is not available.

***Note:*** Intel recommends using the xHCI controller for the USB2.0 ports irrespective of whether USB3.0 ports are implemented. The EHCI controller is provided for legacy OS/ driver compatibility which is generally not required for tablet platforms. Using the xHCI controller will deliver significant power and performance benefits.

When following this recommendation on a platform with no USB3.0 support, the Windows logo requirement of USB debug port may not be met. Please consult with Intel regarding the impact of this.

***Note:*** Unlike the xHCI, bandwidth of all four ports on the EHCI is shared across a single HS (480 Mbps) internal link.

### 18.3.1 Features of EHCI USB 2.0 Controller

The EHCI USB2.0 Controller supports the following features:

- Compliant with the specification for: USB 1.x, 2.0 (1.5 Mbps, 12 Mbps, 480 Mbps).
- 4 Ports shared with xHCI controller
- Enhanced EHCI descriptor caching
- All ports provided through USB Rate Matching Hubs (RMH) to support FS/LS devices
- Supports one Debug port at USB2 transfer rates
- Supports of USB suspend mode including PLL turn off in S0.
- Supports wakeup from suspend states S5 and remote-suspend wakeup
- All USB2 ports provide support for HS/FS/LS devices
- Per port USB disable
- Supports local dynamic clock gating and trunk clock gating
- Supports USB 2.0 LPM (L0, L1 and L2 low power states)

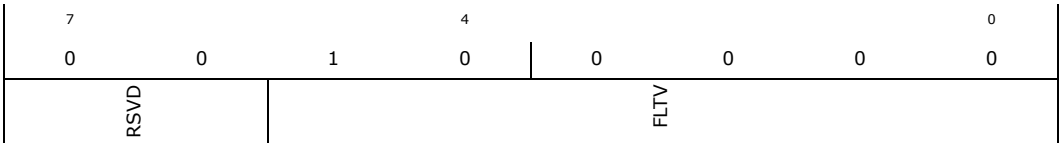
## 18.6.22 Frame Length Adjustment (FLADJ)—Offset 61h



This feature is used to adjust any offset from the clock source that generates the clock that drives the SOF counter. When a new value is written into these six bits, the length of the frame is adjusted. Its initial programmed value is system dependent based on the accuracy of hardware USB clock and is initialized by system BIOS. This register should only be modified when the HChalted bit in the USBSTS register is a one. Changing value of this register while the host controller is operating yields undefined results.

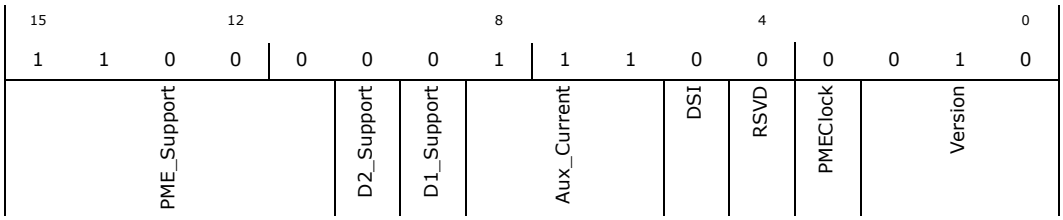
This register should only be written during system initialization before the plug-and-play software has enabled any master-initiated traffic. Values of: 80h implies next capability is MSI 00h implies that MSI capability is hidden. Note: This value is never expected to be programmed.<br><br>**Power Well:** Core |

## 18.6.26 Power Management Capabilities (PM_CAP)—Offset 72h



Normally, this register is read-only to report capabilities to the power management software. In order to report different power management capabilities depending on the system in which the Intel PCH is used, the write access to this register is controlled by the Access Control bit (ACCTRL). The value written to this register does not affect the hardware other than changing the value returned during a read. This register is modified and maintained by BIOS

This will determine how the smallest service interval among active EP s and number of active EP s are used. 0 HS INTR IN periodic active will be used to generate periodic active if Service Interval Threshold OR Numb of EP Threshold values meet the requirement. 1 HS INTR IN periodic active will be used to generate periodic active if Service Interval Threshold AND Numb of EP Threshold values meet the requirement. 2 Always allow HS INTR EP s to be used in the generation of the global Periodic Active indication. 3 Never allow HS INTR EP s to be used in the generation of the global Periodic Active indicaiton<br><br>**Power Well:** Core |

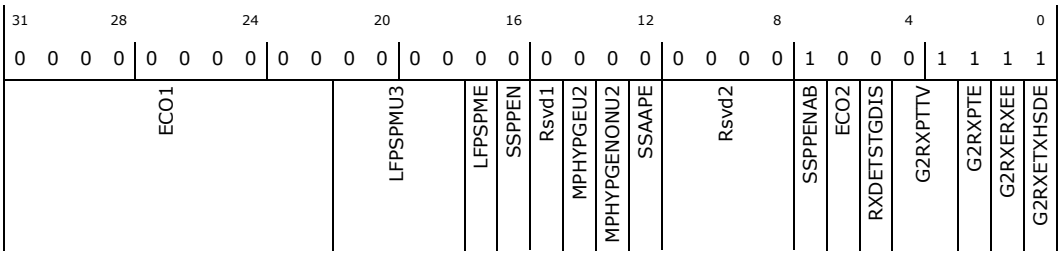
## 18.6.36 Super Speed Configuration 1 (SSCFG1)—Offset B0h



Refer to the switching flows section of this document. Not for EDS

## Access Method

**Type:** PCI Configuration Register (Size: 32 bits)

**Offset:** [B:0, D:20, F:0] + B0h

**Default:** 0000008Fh

| Bit Range | Default & Access | Field Name (ID): Description |
|---|---|---|
| 31:22 | 000h<br>RW | **ECO1:** ECO bits are used during silicon bringup for FIBing.<br><br>**Power Well:** Core |
| 21:18 | 0h<br>RW | **LFPS Power Management in U3 Enable (LFPSPMU3):** This field allows xHC to turn off LFPS Receiver when the port is in U3. This allows the Host Controller to save some extra power (about 50W per port) in idle states if device connected on a port is not Resume capable or Resume enabled. This choice has to be done by BIOS and based on platform knowledge. For example, if an in-box device is not Resume Capable, BIOS could allow xHC to turn-off Rx LFPS when the port is in U3. Each bit represents a port. Bit (16) is for USB3.0 Port 0, Bit (17) is for USB3.0 Port 1 and so on. 0 in a bit position: LFPS Receiver shall be kept enabled when the port is in U3. 1 in a bit position: LFPS Receiver shall be disabled when the port is in U3.<br><br>**Power Well:** SUS |
| 17 | 0b<br>RW | **LFPS Power Management Enable (LFPSPME):** This field provides programmability of LFPS Receiver power management capability when USB3.0 ports are Disabled or in Disconnected state. 0: Do not power manage LFPS receiver. LFPS receivers are enabled in all states. 1: Power manage LFPS receiver. LFPS receivers will be turned off if USB3.0 port is Disabled or Disconnected. Note: Default value is being kept at 0 in case EXI architecture/design takes the path of not doing dynamic Rx LFPS enabling for EXI signature detect and disable LFPS Power Management to keep Rx LFPS buffer on for debug.<br><br>**Power Well:** SUS |

NOTE: This bit will take effect in allowing/preventing USB3 SS port from starting Polling.LFPS only if SSPPENAB is cleared.<br><br>**Power Well:** Core |
