12	0h RO	**HCE:** Host Controller Error (HCE) - RO. Default = 0. 0' = No internal xHC error conditions exist '1' = Internal xHC error condition. This flag shall be set to indicate that an internal error condition has been detected which requires software to reset and reinitialize the xHC. Refer to section 4.24.1 of xhci specification for more information.
11	0h RO	**CNR:** Controller Not Ready (CNR) - RO. Default = '1'. '0' = Ready '1' = Not Ready. Software shall not write any Doorbell or Operational register of the xHC, other than the USBSTS register, until CNR = '0'. This flag is set by the xHC after a Chip Hardware Reset and cleared when the xHC is ready to begin accepting register writes. This flag shall remain cleared ('0') until the next Chip Hardware Reset.
10	0h RO	**SRE:** Save/Restore Error (SRE) -RW1C. Default = '0'. If an error occurs during a Save or Restore operation this bit shall be set to '1'. This bit shall be cleared to '0' when a Save or Restore operation is initiated or when written with '1'. Refer to section 4.23.2 of xhci specification for more information.
9	0h RO	**RSS:** Restore State Status: This bit is similar to the USBSTS.RSS in host mode. When the controller has finished the save process, it will complete the command by setting DSTS.RSS to '0'.
8	0h RO	**SSS:** Save State Status: This bit is similar to the USBSTS.SSS in host mode. When the controller has finished the save process, it will complete the command by setting DSTS.SSS to '0'

19.6.11 PAGESIZE—Offset 28h

Page Size Register Bit Definitions. This register is used by software to enable or disable the reporting of the reception of specific USB Device Notification Transaction Packets. A Notification Enable (Nx, where x = 0 to 15) flag is defined for each of the 16 possible device notification types. If a flag is set for a specific notification type, a Device Notification Event shall be generated when the respective notification packet is received. After reset all notifications are disabled. Refer to section 6.4.2.7. This register shall be written as a Dword. Byte writes produce undefined results.

Bit Range	Default & Access	Description
31:6	0h RW	**CMD_RING_PNTR:** Command Ring Pointer - RW. Default = 0. This field defines high order bits of the initial value of the 64-bit Command Ring Dequeue Pointer. Writes to this field are ignored when Command Ring Running (CRR) = 1. If the CRCR is written while the Command Ring is stopped (CCR = 0), the value of this field shall be used to fetch the first Command TRB the next time the Host Controller Doorbell register is written with the DB Reason field set to Host Controller Command. If the CRCR is not written while the Command Ring is stopped (CCR = 0) then the Command Ring shall begin fetching Command TRBs at the current value of the internal xHC Command Ring Dequeue Pointer. Reading this field always returns 0.
5:4	0h RO	**RSVD14:** reserved

Bit Range	Default & Access	Description
3	0h RW	**CRR:** Command Ring Running (CRR) - RO. Default = 0. This flag is set to 1 if the Run/Stop (R/S) bit is 1 and the Host Controller Doorbell register is written with the DB Reason field set to Host Controller Command. It is cleared to 0 when the Command Ring is stopped after writing a 1 to the Command Stop (CS) or Command Abort (CA) flags, or if the R/S bit is cleared to 0.
2	0h RW	**CA:** Command Abort (CA) - RW1S. Default = 0. Writing a 1 to this bit shall immediately terminate the currently executing command, stop the Command Ring, and generate a Command Completion Event with the Completion Code set to Command Ring Stopped. Refer to section 4.6.1.2 for more information on aborting a command. The next write to the Host Controller Doorbell with DB Reason field set to Host Controller Command shall restart the Command Ring operation. Writes to this flag are ignored by the xHC if Command Ring Running (CRR) = 0. Reading this bit always returns 0.
1	0h RW	**CS:** Command Stop (CS) - RW1S. Default = 0. Writing a 1 to this bit shall stop the operation of the Command Ring after the completion of the currently executing command, and generate a Command Completion Event with the Completion Code set to Command Ring Stopped and the Command TRB Pointer set to the current value of the Command Ring Dequeue Pointer. Refer to section 4.6.1.1 for more information on stopping a command. The next write to the Host Controller Doorbell with DB Reason field set to Host Controller Command shall restart the Command Ring operation. Writes to this flag are ignored by the xHC if Command Ring Running (CRR) = 0. Reading this bit shall always return 0.
0	0h RW	**RCS:** Ring Cycle State (RCS) - RW. This bit identifies the value of the xHC Consumer Cycle State (CCS) flag for the TRB referenced by the Command Ring Pointer. Refer to section 4.9.3 for more information. Writes to this flag are ignored if Command Ring Running (CRR) is 1. If the CRCR is written while the Command Ring is stopped (CRR = 0), then the value of this flag shall be used to fetch the first Command TRB the next time the Host Controller Doorbell register is written with the DB Reason field set to Host Controller Command. If the CRCR is not written while the Command Ring is stopped (CRR = 0), then the Command Ring shall begin fetching Command TRBs using the current value of the internal Command Ring CCS flag. Reading this flag always returns 0.

WPR	DR	RSVD20	WOE	WDE	WCE	RSVD19	CEC	PLC	PRC	OCC	WRC	PEC	CSC	LWS	PIC	PORTSPEED	PP	PLS	PR	OCA	RSVD18	PED	CCS

Bit Range	Default & Access	Description
31	0h RW	**WPR:** Warm Port Reset (WPR) RW1S/RsvdZ. Default = 0. When software writes a 1 to this bit, the Warm Reset sequence as defined in the USB3 Specification is initiated and the PR flag is set to 1. Once initiated, the PR, PRC, and WRC flags shall reflect the progress of the Warm Reset sequence. This flag shall always return 0 when read. Refer to section 4.19.5.1. of XHCI specification. This flag only applies to USB3 protocol ports. For USB2 protocol ports it shall be RsvdZ.
30	0h RW	**DR:** Device Removable (DR) - RO. This flag indicates if this port has a removable device attached. 1 = Device is non-removable. 0 = Device is removable.
29:28	0h RO	**RSVD20:** reserved
27	0h RW	**WOE:** Wake on Over-current Enable (WOE) RWS. Default = 0. Writing this bit to a 1 enables the port to be sensitive to over-current conditions as system wake-up eventsn. Refer to section 4.15 for operational model.
26	0h RW	**WDE:** Wake on Disconnect Enable (WDE) RWS. Default = 0. Writing this bit to a 1 enables the port to be sensitive to device disconnects as system wake-up eventsn. Refer to section 4.15 for operational model.
25	0h RW	**WCE:** Wake on Connect Enable (WCE) RWS. Default = 0. Writing this bit to a 1 enables the port to be sensitive to device connects as system wake-up events . Refer to section 4.15 for operational model.
24	0h RO	**RSVD19:** reserved
23	0h RW	**CEC:** Port Config Error Change (CEC) RW1CS/RsvdZ. Default = 0. This flag indicates that the port failed to configure its link partner. 0 = No change. 1 = Port Config Error detected. Software shall clear this bit by writing a '1' to it. Refer to section 4.19.2 for more information on change bit usage. Note: This flag is valid only for USB3 protocol ports. For USB2 protocol ports this bit shall be RsvdZ.
22	0h RW	**PLC:** Port Link State Change (PLC) RW1CS. Default = 0. This flag is set to 1 due to the following PLS transitions mentioned in the XHCI specification
21	0h RW	**PRC:** Port Reset Change (PRC) RW1CS. Default = 0. This flag is set to 1 due to a '1' to '0' transition of Port Reset (PR). e.g. when any reset processing (Warm or Hot) on this port is complete. Note that this flag shall not be set to 1 if the reset processing was forced to terminate due to software clearing PP or PED to '0'. 0 = No change. 1 = Reset complete. Software shall clear this bit by writing a '1' to it. Refer to section 4.19.5. Refer to section 4.19.2 for more information on change bit usage.
20	0h RW	**OCC:** Over-current Change (OCC) RW1CS. Default = 0. This bit shall be set to a 1 when there is a 0 to 1 or 1 to 0 transition of Over-current Active (OCA). Software shall clear this bit by writing a 1 to it. Refer to section 4.19.2 for more information on change bit usage.
19	0h RW	**WRC:** Warm Port Reset Change (WRC) RW1CS/RsvdZ. Default = 0. This bit is set when Warm Reset processing on this port completes. 0 = No change. 1 = Warm Reset complete. Note that this flag shall not be set to 1 if the Warm Reset processing was forced to terminate due to software clearing PP or PED to '0'. Software shall clear this bit by writing a '1' to it. Refer to section 4.19.5.1. Refer to section 4.19.2 for more information on change bit usage. This bit only applies to USB3 protocol ports. For USB2 protocol ports it shall be RsvdZ.
18	0h RW	**PEC:** Port Enabled/Disabled Change (PEC) RW1CS. Default = 0. 1 = change in PED. 0 = No change. Note that this flag shall not be set if the PED transition was due to software setting PP to 0. Software shall clear this bit by writing a 1 to it. Refer to section 4.19.2 for more information on change bit usage. For a USB2 protocol port, this bit shall be set to 1 only when the port is disabled due to the appropriate conditions existing at the EOF2 point (refer to section 11.8.1 of the USB2 Specification for the definition of a Port Error). For a USB3 protocol port, this bit shall never be set to 1.

Bit Range	Default & Access	Description
17	0h RW	**CSC:** Connect Status Change (CSC) RW1CS. Default = 0. 1 = Change in CCS. 0 = No change. This flag indicates a change has occurred in the ports Current Connect Status (CCS) or Cold Attach Status (CAS) bits. Note that this flag shall not be set if the CCS transition was due to software setting PP to 0, or the CAS transition was due to software setting WPR to 1. The xHC sets this bit to 1 for all changes to the port device connect status , even if system software has not cleared an existing Connect Status Change. For example, the insertion status changes twice before system software has cleared the changed condition, root hub hardware will be setting an already-set bit (i.e., the bit will remain 1). Software shall clear this bit by writing a 1 to it. Refer to section 4.19.2 for more information on change bit usage.
16	0h RW	**LWS:** Port Link State Write Strobe (LWS) RW. Default = 0. When this bit is set to 1 on a write reference to this register, this flag enables writes to the PLS field. When 0, write data in PLS field is ignored. Reads to this bit return 0.
15:14	0h RW	**PIC:** Port Indicator Control (PIC) RWS. Default = 0. Writing to these bits has no effect if the Port Indicators (PIND) bit in the HCCPARAMS register is a 0.
13:10	0h RW	**PORTSPEED:** Port Speed (Port Speed) ROS. Default = 0. This field identifies the speed of the connected USB Device. This field is only relevant if a device is connected (CCS = 1) in all other cases this field shall indicate Undefined Speed. (more information in the XHCI specification)
9	1h RW	**PP:** Port Power (PP) RWS. Default = 1. This flag reflects a port's logical, power control state. Because host controllers can implement different methods of port power switching, this flag may or may not represent whether (VBus) power is actually applied to the port. When PP equals a '0' the port is nonfunctional and shall not report attaches, detaches, or Port Link State (PLS) changes. However, the port shall report over-current conditions when PP = 0 if PPC = 0. After modifying PP, software shall read PP and confirm that it is reached its target state before modifying it again , undefined behavior may occur if this procedure is not followed. 0 = This port is in the Powered-off state. 1 = This port is not in the Powered-off state. If the Port Power Control (PPC) flag in the HCCPARAMS register is '1', then xHC has port power control switches and this bit represents the current setting of the switch ('0' = off, '1' = on). If the Port Power Control (PPC) flag in the HCCPARAMS register is '0', then xHC does not have port power control switches and each port is hard wired to power, and not affected by this bit. When an over-current condition is detected on a powered port, the xHC shall transition the PP bit in each affected port from a 1 to 0 (removing power from the port). Note: If this is an SSIC Port, then the DSP Disconnect process is initiated by '1' to '0' transition of PP. Refer to section 5.1.2 in the SSIC Spec for more information. Refer to section 4.19.4 for more information.
8:5	5h RW	**PLS:** Port Link State (PLS) RWS. Default = RxDetect (5). This field is used to power manage the port and reflects its current link state. When the port is in the Enabled state, system software may set the link U state by writing this field. System software may also write this field to force a Disabled to Disconnected state transition of the port.
4	0h RW	**PR:** Port Reset (PR) RW1S. Default = 0. 1 = Port Reset signaling is asserted. 0 = Port is not in Reset. When software writes a 1 to this bit generating a 0 to 1 transition, the bus reset sequence is initiated ; USB2 protocol ports shall execute the bus reset sequence as defined in the USB2 Spec. USB3 protocol ports shall execute the Hot Reset sequence as defined in the USB3 Spec. PR remains set until reset signaling is completed by the root hub. Note that software shall write a 1 to this flag to transition a USB2 port from the Polling state to the Enabled state. Refer to sections 4.15.2.3 and 4.19.1.1. This flag is 0 if PP is 0.
3	0h RW	**OCA:** Over-current Active (OCA) RO. Default = 0. 1 = This port currently has an over-current condition. 0 = This port does not have an over-current condition. This bit shall automatically transition from a 1 to a 0 when the over-current condition is removed.
2	0h RO	**RSVD18:** reserved

Bit Range	Default & Access	Description
1	0h RW	**PED:** Port Enabled/Disabled (PED) RW1CS. Default = 0. 1 = Enabled. 0 = Disabled. Ports may only be enabled by the xHC. Software cannot enable a port by writing a 1 to this flag. A port may be disabled by software writing a 1 to this flag. This flag shall automatically be cleared to 0 by a disconnect event or other fault condition. Note that the bit status does not change until the port state actually changes. There may be a delay in disabling or enabling a port due to other host controller or bus events. When the port is disabled (PED = 0) downstream propagation of data is blocked on this port, except for reset. For USB2 protocol ports: When the port is in the Disabled state, software shall reset the port (PR = 1) to transition PED to 1 and the port to the Enabled state. For USB3 protocol ports: When the port is in the Polling state (after detecting an attach), the port shall automatically transition to the Enabled state and set PED to 1 upon the completion of successful link training. When the port is in the Disabled state, software shall write a 5 (RxDetect) to the PLS field to transition the port to the Disconnected state. Refer to section 4.19.1.2. PED shall automatically be cleared to 0 when PR is set to 1, and set to 1 when PR transitions from 1 to 0 after a successful reset. Refer to Port Reset (PR) bit for more information on how the PED bit is managed. Note that when software writes this bit to a 1, it shall also write a 0 to the PR bit . This flag is 0 if PP is 0.
0	0h RW	**CCS:** Current Connect Status (CCS) ROS. Default = 0. 1 = A device is connected to the port. 0 = A device is not connected. This value reflects the current state of the port, and may not correspond directly to the event that caused the Connect Status Change (CSC) bit to be set to 1. Refer to sections 4.19.3 and 4.19.4 for more details on the Connect Status Change (CSC) assertion conditions. This flag is 0 if PP is 0.

7:4	0h RW	**HIRD:** Host Initiated Resume Duration (HIRD) - RW. Default = '0'. System software sets this field to indicate to the recipient device how long the xHC will drive resume if it (the xHC) initiates an exit from L1. The HIRD value is encoded as follows: Value Description 0h 50 s. (default) 1h 125 s. 2h 200 s. Fh 1.175 ms. The value of 0000b is interpreted as 50 s. Each incrementing value up adds 75 s. to the previous value. For example, 0001b is 125 s, 0010b is 200s and so on. Based on this rule, the maximum value resume drive time is at encoding value 1111b which represents 1.2ms. Note that the HIRD field is used by both software and hardware controlled LPM. Refer to section 4.23.5.1.1 of xhci specification for more information on HIRD use. Refer to Section 4.1 of the USB2 LPM spec for more information on the use of the HIRD field.

13:10	0h RW	**HIRDD:** Best Effort Service Latency Deep (BESLD) - RWS. Default = 0. System software sets this field to indicate to the recipient device how long the xHC will drive resume on an exit from U2. Refer to section 4.23.5.1.1.1 for more information on BESLD use. The BESLD value encoding is defined in Table 13. Refer to section 5.2.6 for information on how DBESLD may be used to establish an initial value for BESLD
9:2	0h RW	**L1TIMEOUT:** L1 Timeout RWS. Default = 00h. Timeout value for the L1 inactivity timer (LPM Timer). This field shall be set to 00h by the assertion of PR to 1. Refer to section 4.23.5.1.1.1 for more information on L1 Timeout operation. The following are permissible values: for 00h 128 s. (default). for 01h 256 s. for 02h 512 s. for 03h 768 s. . . . for FFh 65,280 s.
1:0	0h RW	**HIRDM:** Host Initiated Resume Duration Mode (HIRDM) - RWS. Default = 0h. Indicates which HIRD value should be used. The following are permissible values: for 0 Initiate L1 using BESL only on timeout. (default). for 1 Initiate L1 using BESLD on timeout. If rejected by device, initiate L1 using BESL. for 3-2 Reserved.

19.6.22 PORTSC2—Offset 430h

A host controller shall implement one or more port registers. The number of port registers implemented by a particular instantiation of a host controller is documented in the HCSPARAMS1 register (Section 5.3.3). Software uses this information as an input parameter to determine how many ports need to be serviced

Bit Range	Default & Access	Description
31	0h RW	**WPR:** Warm Port Reset (WPR) RW1S/RsvdZ. Default = 0. When software writes a 1 to this bit, the Warm Reset sequence as defined in the USB3 Specification is initiated and the PR flag is set to 1. Once initiated, the PR, PRC, and WRC flags shall reflect the progress of the Warm Reset sequence. This flag shall always return 0 when read. Refer to section 4.19.5.1. This flag only applies to USB3 protocol ports. For USB2 protocol ports it shall be RsvdZ.
30	0h RW	**DR:** Device Removable (DR) - RO. This flag indicates if this port has a removable device attached. 1 = Device is non-removable. 0 = Device is removable.
29:28	0h RO	**RSVD25:** reserved
27	0h RW	**WOE:** Wake on Over-current Enable (WOE) RWS. Default = 0. Writing this bit to a 1 enables the port to be sensitive to over-current conditions as system wake-up eventsn. Refer to section 4.15 for operational model.
26	0h RW	**WDE:** Wake on Disconnect Enable (WDE) RWS. Default = 0. Writing this bit to a 1 enables the port to be sensitive to device disconnects as system wake-up eventsn. Refer to section 4.15 for operational model.
25	0h RW	**WCE:** Wake on Connect Enable (WCE) RWS. Default = 0. Writing this bit to a 1 enables the port to be sensitive to device connects as system wake-up events . Refer to section 4.15 for operational model.
24	0h RO	**RSVD24:** reserved
23	0h RW	**CEC:** Port Config Error Change (CEC) RW1CS/RsvdZ. Default = 0. This flag indicates that the port failed to configure its link partner. 0 = No change. 1 = Port Config Error detected. Software shall clear this bit by writing a '1' to it. Refer to section 4.19.2 of XHCI specification for more information on change bit usage. Note: This flag is valid only for USB3 protocol ports. For USB2 protocol ports this bit shall be RsvdZ.
22	0h RW	**PLC:** Port Link State Change (PLC) RW1CS. Default = 0. This flag is set to 1 due to the PLS transitions in the XHCI specification
21	0h RW	**PRC:** Port Reset Change (PRC) RW1CS. Default = 0. This flag is set to 1 due to a '1' to '0' transition of Port Reset (PR). e.g. when any reset processing (Warm or Hot) on this port is complete. Note that this flag shall not be set to 1 if the reset processing was forced to terminate due to software clearing PP or PED to '0'. 0 = No change. 1 = Reset complete. Software shall clear this bit by writing a '1' to it. Refer to section 4.19.5.of XHCI specification. Refer to section 4.19.2 of XHCI specification. for more information on change bit usage.
20	0h RW	**OCC:** Over-current Change (OCC) RW1CS. Default = 0. This bit shall be set to a 1 when there is a 0 to 1 or 1 to 0 transition of Over-current Active (OCA). Software shall clear this bit by writing a 1 to it. Refer to section 4.19.2 for more information on change bit usage.
19	0h RW	**WRC:** Warm Port Reset Change (WRC) RW1CS/RsvdZ. Default = 0. This bit is set when Warm Reset processing on this port completes. 0 = No change. 1 = Warm Reset complete. Note that this flag shall not be set to 1 if the Warm Reset processing was forced to terminate due to software clearing PP or PED to '0'. Software shall clear this bit by writing a '1' to it. Refer to section 4.19.5.1. Refer to section 4.19.2 for more information on change bit usage. This bit only applies to USB3 protocol ports. For USB2 protocol ports it shall be RsvdZ.
18	0h RW	**PEC:** Port Enabled/Disabled Change (PEC) RW1CS. Default = 0. 1 = change in PED. 0 = No change. Note that this flag shall not be set if the PED transition was due to software setting PP to 0. Software shall clear this bit by writing a 1 to it. Refer to section 4.19.2 for more information on change bit usage. For a USB2 protocol port, this bit shall be set to 1 only when the port is disabled due to the appropriate conditions existing at the EOF2 point (refer to section 11.8.1 of the USB2 Specification for the definition of a Port Error). For a USB3 protocol port, this bit shall never be set to 1.

Bit Range	Default & Access	Description
17	0h RW	**CSC:** Connect Status Change (CSC) RW1CS. Default = 0. 1 = Change in CCS. 0 = No change. This flag indicates a change has occurred in the ports Current Connect Status (CCS) or Cold Attach Status (CAS) bits. Note that this flag shall not be set if the CCS transition was due to software setting PP to 0, or the CAS transition was due to software setting WPR to 1. The xHC sets this bit to 1 for all changes to the port device connect status , even if system software has not cleared an existing Connect Status Change. For example, the insertion status changes twice before system software has cleared the changed condition, root hub hardware will be setting an already-set bit (i.e., the bit will remain 1). Software shall clear this bit by writing a 1 to it. Refer to section 4.19.2 for more information on change bit usage.
16	0h RW	**LWS:** Port Link State Write Strobe (LWS) RW. Default = 0. When this bit is set to 1 on a write reference to this register, this flag enables writes to the PLS field. When 0, write data in PLS field is ignored. Reads to this bit return 0.
15:14	0h RW	**PIC:** Port Indicator Control (PIC) RWS. Default = 0. Writing to these bits has no effect if the Port Indicators (PIND) bit in the HCCPARAMS register is a 0
13:10	0h RW	**PORTSPEED:** Port Speed (Port Speed) ROS. Default = 0. This field identifies the speed of the connected USB Device. This field is only relevant if a device is connected (CCS = 1) in all other cases this field shall indicate Undefined Speed.
9	1h RW	**PP:** Port Power (PP) RWS. Default = 1. This flag reflects a port's logical, power control state. Because host controllers can implement different methods of port power switching, this flag may or may not represent whether (VBus) power is actually applied to the port. When PP equals a '0' the port is nonfunctional and shall not report attaches, detaches, or Port Link State (PLS) changes. However, the port shall report over-current conditions when PP = 0 if PPC = 0. After modifying PP, software shall read PP and confirm that it is reached its target state before modifying it again , undefined behavior may occur if this procedure is not followed. 0 = This port is in the Powered-off state. 1 = This port is not in the Powered-off state. If the Port Power Control (PPC) flag in the HCCPARAMS register is '1', then xHC has port power control switches and this bit represents the current setting of the switch ('0' = off, '1' = on). If the Port Power Control (PPC) flag in the HCCPARAMS register is '0', then xHC does not have port power control switches and each port is hard wired to power, and not affected by this bit. When an over-current condition is detected on a powered port, the xHC shall transition the PP bit in each affected port from a 1 to 0 (removing power from the port). Note: If this is an SSIC Port, then the DSP Disconnect process is initiated by '1' to '0' transition of PP. Refer to section 5.1.2 in the SSIC Spec for more information. Refer to section 4.19.4 for more information.
8:5	5h RW	**PLS:** Port Link State (PLS) RWS. Default = RxDetect (5). This field is used to power manage the port and reflects its current link state. When the port is in the Enabled state, system software may set the link U state by writing this field. System software may also write this field to force a Disabled to Disconnected state transition of the port.
4	0h RW	**PR:** Port Reset (PR) RW1S. Default = 0. 1 = Port Reset signaling is asserted. 0 = Port is not in Reset. When software writes a 1 to this bit generating a 0 to 1 transition, the bus reset sequence is initiated ; USB2 protocol ports shall execute the bus reset sequence as defined in the USB2 Spec. USB3 protocol ports shall execute the Hot Reset sequence as defined in the USB3 Spec. PR remains set until reset signaling is completed by the root hub. Note that software shall write a 1 to this flag to transition a USB2 port from the Polling state to the Enabled state. Refer to sections 4.15.2.3 and 4.19.1.1. of XHCI specification. This flag is 0 if PP is 0.
3	0h RW	**OCA:** Over-current Active (OCA) RO. Default = 0. 1 = This port currently has an over-current condition. 0 = This port does not have an over-current condition. This bit shall automatically transition from a 1 to a 0 when the over-current condition is removed.
2	0h RO	**RSVD23:** reserved

Bit Range	Default & Access	Description
1	0h RW	**PED:** Port Enabled/Disabled (PED) RW1CS. Default = 0. 1 = Enabled. 0 = Disabled. Ports may only be enabled by the xHC. Software cannot enable a port by writing a 1 to this flag. A port may be disabled by software writing a 1 to this flag. This flag shall automatically be cleared to 0 by a disconnect event or other fault condition. Note that the bit status does not change until the port state actually changes. There may be a delay in disabling or enabling a port due to other host controller or bus events. When the port is disabled (PED = 0) downstream propagation of data is blocked on this port, except for reset. For USB2 protocol ports: When the port is in the Disabled state, software shall reset the port (PR = 1) to transition PED to 1 and the port to the Enabled state. For USB3 protocol ports: When the port is in the Polling state (after detecting an attach), the port shall automatically transition to the Enabled state and set PED to 1 upon the completion of successful link training. When the port is in the Disabled state, software shall write a 5 (RxDetect) to the PLS field to transition the port to the Disconnected state. Refer to section 4.19.1.2. of xhci specification. PED shall automatically be cleared to 0 when PR is set to 1, and set to 1 when PR transitions from 1 to 0 after a successful reset. Refer to Port Reset (PR) bit for more information on how the PED bit is managed. Note that when software writes this bit to a 1, it shall also write a 0 to the PR bit. This flag is 0 if PP is 0.
0	0h RW	**CCS:** Current Connect Status (CCS) ROS. Default = 0. 1 = A device is connected to the port. 0 = A device is not connected. This value reflects the current state of the port, and may not correspond directly to the event that caused the Connect Status Change (CSC) bit to be set to 1. Refer to sections 4.19.3 and 4.19.4 for more details on the Connect Status Change (CSC) assertion conditions. This flag is 0 if PP is 0.

31:2	0h RO	**RSVD29:** reserved
1	0h RW	**IE:** Interrupt Enable (IE) RW. Default = 0. This flag specifies whether the Interrupter is capable of generating an interrupt. When this bit and the IP bit are set (1), the Interrupter shall generate an interrupt when the Interrupter Moderation Counter reaches 0. If this bit is 0, then the Interrupter is prohibited from generating interrupts.
0	0h RW	**IP:** Interrupt Pending (IP) - RW1C. Default = 0. This flag represents the current state of the Interrupter. If IP = 1, an interrupt is pending for this Interrupter. A 0 value indicates that no interrupt is pending for the Interrupter. Refer to section 4.17.5 of XHCI specification for the conditions that modify the state of this flag.

19.6.27 IMOD—Offset 464h

Interrupter Moderation Register. Software may use this register to pace (or even out) the delivery of interrupts to the host CPU. This register provides a guaranteed inter-interrupt delay between interrupts asserted by the xHC, regardless of USB traffic conditions. To independently validate configuration settings, software may use the following algorithm to convert the inter-interrupt Interval value to the common 'interrupts/sec' performance metric:

31:16	0h RW	**IMODC:** Interrupt Moderation Counter (IMODC) - RW. Default = undefined. Down counter. Loaded with the IMODI value whenever IP is cleared to '0', counts down to '0', and stops. The associated interrupt shall be signaled whenever this counter is '0', the Event Ring is not empty, the IE and IP flags = '1', and EHB = '0'. This counter may be directly written by software at any time to alter the interrupt rate.

Bit Range	Default & Access	Description
15:0	fa0h RW	**IMODI:** Interrupt Moderation Interval (IMODI) - RW. Default = '4000' (~1ms). Minimum inter-interrupt interval. The interval is specified in 250ns increments. A value of '0' disables interrupt throttling logic and interrupts shall be generated immediately if IP = '0', EHB = '0', and the Event Ring is not empty.

This bit controls the endian mode for data accesses. 0: Little-endian (default) 1: Big-endian In big-endian mode, DMA access (both read and write) for packet data will utilize a Byte Invariant Big-Endian mode (see Section Little-Endian and Big-Endian in the DWC SuperSpeed USB 3.0 Controller User Guide). Note: Since AXI requires byteinvariant endianness, setting DescBigend and DatBigEnd to one causes an address invariant transform to be applied, which is not appropriate.See section 9.3 and 9.4 of the AMBA AXI Specification. Hence for an AXI master (DWC_USB3_MBUS_TYPE=1), this bit must be set to zero.

If this bit is set to 0, the AHB master may still use INCR burst type at the beginning and end bursts of transfers to align the address. The middle bursts are INCR4/8/16, depending when the type is enabled.

10:9	3h RW	**DTCT:** Device Timeout Coarse Tuning: This field is a Host mode parameter which determines how long the host waits for a response from device before considering a timeout. The core first checks the DTCT value. If it is 0, then the timeout value is defined by the DTFT. If it is non-zero, then it uses the following timeout values: n 2'b00: 0 usec -) use DTFT value instead n 2'b01: 500 usec n 2'b10: 1.5 msec n 2'b11: 6.5 msec
8:0	0h RW	**DTFT:** Device Timeout Fine Tuning: This field is a Host mode parameter which determines how long the host waits for a response from device before considering a timeout. For DTFT field to take effect, DTCT must be set to 2'b00. The DTFT value is the number of 125 MHz clocks * 256 to count before considering a device timeout. For the 125 MHz clk (8 ns period), this is calculated as follows: (DTFT value) * 256 * (8 ns) Quick Reference: n if DTFT = 0x2, 2*256*8 = 4usec timeout n if DTFT = 0x5, 5*256*8 = 10usec timeout n if DTFT = 0xA, 10*256*8 = 20usec timeout n if DTFT = 0x10, 16*256*8 = 32usec timeout n if DTFT = 0x19, 25*256*8 = 51usec timeout n if DTFT = 0x31, 49*256*8 = 100usec timeout n if DTFT = 0x62, 98*256*8 = 200usec timeout

The application uses this bit to control the DWC_usb3 core's RSP/HNP capabilities. n 1'b0: RSP/HNP capability is not enabled. n 1'b1: RSP/HNP capability is enabled. Note: This bit is writable only if RSP/HNP mode is specified for Mode of Operation in coreConsultant, that is when DWC_USB3_EN_OTG != 0 and DWC_USB3_MODE = DRD. If RSP/HNP mode is not specified, this bit is Read Only, and is set to 1'b0.
0	0h RW	**SRPCap:** SRP Capability: The application uses this bit to control the DWC_usb3 core's SRP capabilities. n 1'b0: SRP capability is not enabled. n 1'b1: SRP capability is enabled. If this bit is not set for B-device, it cannot request the connected A-device (host) to activate Vbus and start a session. If this bit is not set for A-device, it cannot detect the SRP from B-device (device) to activate Vbus and start a session. Note: This bit is writable only if OTG is enabled in coreConsultant (DWC_USB3_EN_OTG !=0). If OTG is not enabled, then this bit is Read Only and is set to 1'b0.

6	1h RW	**PeriMode:** Peripheral Mode: Application uses this bit to program the core to work as a peripheral or as a host. n 1'b0: The OTG device acts as a host n 1'b1: The OTG device acts as a peripheral
5	0h RW	**PrtPwrCtl:** Port Power Control: Application sets this bit to initiate Vbus drive when it is an A-device. The application should clearthis bit only if it wants to switch off the Vbus to B-device. The core clears this bit in the following conditions: n Transition from any state to A-IDLE state defined in OTG2.0 state machine. n When AIDL_BDIS_TOUT occurs in A_SUSPEND n When A_WAIT_BCON_TOUT occurs in A_WAIT_BCON n Transition to any B- state defined in OTG2.0 state machine
4	0h RW	**HNPReq:** HNP Request: n 1'b0: No HNP request n 1'b1: HNP request The application sets this bit to initiate a HNP request to the connected USB host. The application clears this bit by writing a 1'b0 when either of the following is detected: n OEVT.OTGBDevBHostEndEvnt n OEVT.OTGBDevVBusChngEvnt

Bit Range	Default & Access	Description
3	0h RW	**SesReq:** Session Request: n 1'b0: No session request n 1'b1: Session request The application sets this bit to initiate a session request on the USB. Writing 1'b1 to this field will trigger the core to send SRP (data line pulsing) on PHY interface. In the absence of OEVT.OTGBDevSessVldDetEvnt after a session request, the application must wait for atleast TB_SRP_FAIL time (6 secs) before initiating another session request. This field returns 1'b0 when read.
2	0h RW	**TermSelDLPulse:** TermSel DLine Pulsing Selection: This bit selects utmi_termselect to drive data line pulse during SRP. n 1'b0: Data line pulsing using utmi_txvalid (default). n 1'b1: Data line pulsing using utmi_termsel.
1	0h RW	**DevSetHNPEn:** Device Set RSP/HNP Enable: n 1'b0: RSP/HNP is not enabled in the application n 1'b1: RSP/HNP is enabled in the application The application sets this bit in the following scenario: n In HS/FS mode, when it successfully receives a SetFeature.SetHNPEnable command from the connected USB host. n In SS mode, when it has sent a b3_ntf_hst_rel to the A-device, or the A-device has sent an a3_ntf_host_req. Note: The terminology RSP is used when the core is operating in SS mode, and HNP is used when the core is operating in non-SS mode.
0	0h RW	**HstSetHNPEn:** Host Set RSP/HNP Enable: n 1'b0: Host Set RSP/HNP is not enabled n 1'b1: Host Set RSP/HNP is enabled The application sets this bit in the following scenario: n In HS/FS mode, when it has successfully enabled HNP (using the SetFeature.SetHNPEnable command) from the connected device. n In SS mode, when it has successfully enabled b3_rsp_enable feature in RSP-capable Device using SetFeature command while operating as an A-Host, or when it has received a b3_ntf_hst_rel through SetFeature command while operating as A-peripheral. Note: The terminology RSP is used when the core is operating in SS mode, and HNP is used when the core is operating in non-SS mode.

2	0h RO	**HstNegSts:** Host Negotiation Status: The core updates this bit when any of the following bits is set: n OEVTEN.OTGADevHNPChngEvnt n OEVTEN.OTGBDevHNPChngEvnt This bit indicates Host Negotiation Success or Failure. n 1'b0: Host negotiation failure. In A-device, for HS/FS, this indicates an imminent end of session indication from the core. In B-device, for HS/LS, it indicates that the timer used to wait for an A-device to signal a connection (b_ase0_brst_tmout in OTG 2.0) timed out resulting in B-device staying as B-peripheral. n 1'b1: Host negotiation success. This indicates that the host negotiation was successful. Note: This bit is a pplicable only for OTG 2.0 mode of operation.

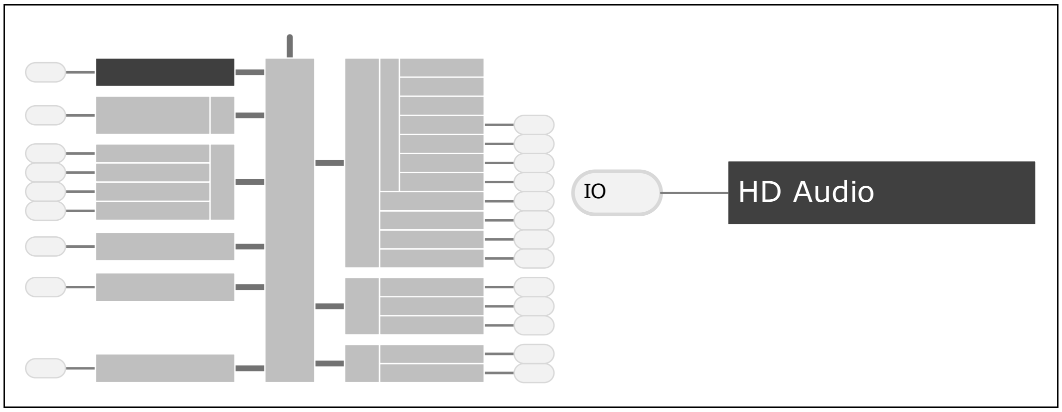
20 Intel® High Definition Audio

The Intel® High Definition Audio (Intel® HD Audio) is an architecture and infrastructure to support high-quality audio implementations for PCs.

Note: The High Definition Audio interface is multiplexed on the same balls as LPE_I2S[1:0].

Note: When High Definition Audio is active, the LPE Audio functionality is disabled.



The Intel® High Definition Audio (Intel® HD Audio) controller consists of a set of DMA engines that are used to move samples of digitally encoded data between system memory and internal/external CODECs. The controller communicates with the internal/ external CODECs over the Intel® HD Audio serial link.The output DMA engines move digital data from system memory to a D-A converter in a CODEC. The SoC implements a single Serial Data Output (SDO) signal that is connected to the external CODECs. The input DMA engines move digital data from the A-D converter in the CODEC to system memory. The platform supports up to two external CODECs by implementing two Serial Data Input (SDI) signals, each being dedicated to a single CODEC.

Audio software renders outbound, and processes inbound data to/from buffers in memory. The location of the individual buffers is described by a Buffer Descriptor List that is fetched and processed by the audio controller. The data in the buffers is arranged in a pre-defined format. The output DMA engines fetch the digital data from memory and reformat it based on the programmed sample rate, bits/sample and number of channels. The data from the output DMA engines is then combined and serially sent to the CODEC(s) over the Intel® HD Audio link. The input DMA engines receive data from the CODEC(s) over the Intel® HD Audio link and format the data based on the programmable attributes for that stream. The data is then written to memory in the predefined format for software to process. Each DMA engine moves one “stream” of data. A single CODEC can accept or generate multiple “streams” of data, one for each A-D or D-A converter in the CODEC. Multiple CODECs can accept the same output “stream” processed by a single DMA engine.

Codec commands and responses are also transported to and from the CODEC via DMA engines. The DMA engine dedicated to transporting commands from the Command Output Ring Buffer (CORB) in memory to the CODEC(s) is called the CORB engine. The DMA engine dedicated to transporting responses from the CODEC(s) to the Response Input Ring Buffer in memory is called the RIRB engine. Every command sent to a CODEC yields a response from that CODEC. Some commands are "broadcast" type commands in which case a response will be generated from each CODEC. A CODEC may also be programmed to generate unsolicited responses, which the RIRB engine also processes. The platform also supports Programmed IO-based Immediate Command/Response transport mechanism that can be used by BIOS prior to memory initialization.

20.1 Signal Descriptions

Please see Chapter 2, "Physical Interfaces" for additional details.

The signal description table has the following headings:

- **Signal Name:** The name of the signal/pin
- **Direction**: The buffer direction can be either input, output, or I/O (bidirectional)
- **Platform Power**: The reference power plane.
- **Description**: A brief explanation of the signal's function

Table 223. Signals

Signal Name	Direction Plat. Power	Description
HDA_RST#	O VAUD	**Intel HD Audio Reset:** Master H/W reset to external Codecs
HDA_SYNC	O VAUD	**Intel HD Audio Sync:** 48 kHz fixed rate
HDA_CLK	O VAUD	**Intel HD Audio Bit Clock (Output):** 24 MHz serial data clock generated by the Intel HD Audio controller
HDA_SDO	O VAUD	**Intel HD Audio Data Out:** Serial TDM data output to the Codec(s). The serial output is double-pumped for a bit rate of 48 Mb/s
HDA_SDI[1:0]	I/O VAUD	**Intel HD Audio Serial Data In[1:0]:** Serial TDM data input from the CODEC(s). The serial input is single-pumped for a bit rate of 24 Mb/s.
HDA_LPE_RCOMP	O	Impedance/ current Compensation Output.

The signals in the table above are all muxed and maybe used by other functions.

20.2 Features

The Intel® HD Audio Controller supports the following features:

- Supports MSI and legacy interrupt delivery
- Support for ACPI D3 and D0 Device States
- Supports up to:
  - 6 streams (three input, three output)
  - 16 channels per stream
  - 32 bits/sample
  - 192 kHz sample rate
- 24 MHz HDA_CLK supports
  - SDO double pumped at 48 Mb/s
  - SDI single pumped at 24 Mb/s
- Supports 1.5V mode only
- Supports optional Immediate Command/Response mechanism

20.4 Register Map

See Chapters 3 and 4 for additional information.

Note: PCI mode is supported, but not PCIe mode. Must set TM1.HAPD bit to 1b for PCI mode.

15	0h RW1C	**PMES:** PME Status (PMES): This bit is set when the Intel HD Audio controller would normally assert the PME# signal independent of the state of the PME_En bit. This bit resides in the Suspend well. This bit is in the Suspend well and cleared on a power-on reset. Software must not make assumptions about the reset state of this bit and must set it appropriately.
14:9	0h RO	**Reserved_1:** Reserved
8	0h RW	**PMEE:** PME enable
7:2	0h RO	**Reserved_2:** reserved
1:0	0h RW	**PS:** Power State (PS): This field is used both to determine the current power state of the Intel HD Audio controller and to set a new power state. The values are: 00 D0 state 11 D3HOT state If software attempts to write a value of 10b or 01b in to this field, the write operation must complete normally; however, the data is discarded and no state change occurs. When in the D3HOT states, the Intel HD Audio controllers configuration space is available, but the I/O and memory spaces are not. Additionally, interrupts are blocked. When software changes this value from the D3HOT state to the D0 state, an internal warm (soft) reset is generated, and software must re-initialize the function.

FLUSH_CONTROL

CONTROLLER_RESET

Bit Range	Default & Access	Description
31:9	0h RO	**RESERVED0:** reserved
8	0h RW	**ACCEPT_UNSOLICITED_RESPONSE_ENABLE:** If UNSOL is a 1 Unsolicited Responses from the codecs are accepted by the controller and placed into the Response Input Ring Buffer. If UNSOL is a 0 unsolicited responses are not accepted and dropped on the floor.
7:2	00h RO	**RESERVED1:** reserved
1	0h RW	**FLUSH_CONTROL:** Writing a 1 to this bit initiates a flush. When the flush completion is received by the controller hardware sets the Flush Status bit and clears this Flush Control bit. Before a flush cycle is initiated the DMA Position Buffer must be programmed with a valid memory address by software but the DMA Position Buffer bit 0 need not be set to enable the position reporting mechanism. Also all streams must be stopped the associated RUN bit must be 0 . When the flush is initiated the controller will flush pipelines to memory to guarantee that the hardware is ready to transition to a D3 state. Setting this bit is not a critical step in the power state transition if the content of the FIFOs is not critical.
0	0h RW	**CONTROLLER_RESET:** Writing a 0 to this bit causes the Intel HD Audio controller to be reset. All state machines FIFO s and non Suspend well memory mapped configuration registers except ECAP and PCI Configuration Registers in the controller will be reset. The Intel HD Audio link RESET signal will be asserted and all other link signals will be driven to their reset values. After the hardware has completed sequencing into the reset state it will report a 0 in this bit. Software must read a 0 from this bit to verify that the controller is in reset. Writing a 1 to this bit causes the controller to exit its reset state and de assert the Intel HD Audio link RESET signal. Software is responsible forsetting clearing this bit such that the minimum Intel HD Audio link RESET signal assertion pulse width specification is met. When the controller hardware is ready to begin operation it will report a1 in this bit. Software must read a 1 from this bit before accessing any controller registers. The CRST bit defaults to a 0 after hardware reset therefore software needs to write a 1 to this bit to begin operation. Note thatthe CORB RIRB RUN bits and all Stream RUN bits must be verified cleared to zero before CRST is written to 0 asserted in order to assure a clean re start. When setting or clearing CRST software must ensure that minimum link timing requirements minimum RESET assertion time etc. are met. When CRST is 0 indicating that the controller is in reset writes to all Intel HD Audio memory mapped registers are ignored as if the device is not present. The only exception is the Global Control register containing the CRST bit itself. The Global Control register is write able as a DWord Word or Byte even when CRST is 0 if the byte enable for the byte containing the CRST bit Byte Enable 0 is active. If Byte Enable 0 is not active writes to the Global Control register will be ignored when CRST is 0. When CRST is 0 reads to Intel HD Audio memory mapped registers will return their default value except for registers that are not reset with PLTRST or on a D3hot gt D0 transition.

IMMEDIATE_RESPONSE_READ																															

Bit Range	Default & Access	Description
31:0	0h RO	**IMMEDIATE_RESPONSE_READ:** This register contains the response received from a codec resulting from a command sent via the Immediate Command mechanism. If multiple codecs responded in the same frame there is no guarantee as to which response will be latched. Therefore broadcast type commands must not be issued via the Immediate Command mechanism.

RESERVED0														IMMEDIATE_RESULT_VALID	IMMEDIATE_COMMAND_BUSY

Bit Range	Default & Access	Description
15:2	0000h RO	**RESERVED0:** reserved
1	0h RW	**IMMEDIATE_RESULT_VALID:** This bit is set to a 1 by hardware when a new response is latched into the IRR register. This is a status flag indicating that software may read the response from the Immediate Response register. Software must clear this bit by writing a one to it before issuing a new command so that the software may determine when a new response has arrived.
0	0h RW	**IMMEDIATE_COMMAND_BUSY:** When this bit as read as a 0 it indicates that a new command may be issued using the Immediate Command mechanism. When this bit transitions from a 0 to a 1 via software writing a 1 the controller issues the command currently stored in the Immediate Command register to the codec over the link. When the corresponding response is latched into the Immediate Response register the controller hardware sets the IRV flag and clears the ICB bit back to 0. SW may write this bit to a 0 if the bit fails to return to 0 after a reasonable timeout period. Note that an Immediate Command must not be issued while the CORB RIRB mechanism is operating otherwise the responses conflict. This must be enforced by software.

DMA_POSITION_LOWER_BASE_ADDRESS																									DMA_POSITION_LOWER_BASE_UNIMPLEMENTED_BITS						DMA_POSITION_BUFFER_ENABLE

Bit Range	Default & Access	Description
31:7	0h RW	**DMA_POSITION_LOWER_BASE_ADDRESS:** Lower 32 bits of the DMA Position Buffer Base Address. This register field must not be written when any DMA engine is running or the DMA transfer may be corrupted. This same address is used by the Flush Control and must be programmed with a valid value before the FLCNRTL bit is set.
6:1	00h RO	**DMA_POSITION_LOWER_BASE_UNIMPLEMENTED_BITS:** Hardwired to 0 to force 128 byte buffer alignment for cache line write optimizations.
0	0h RW	**DMA_POSITION_BUFFER_ENABLE:** When this bit is set to a 1 the controller will write the DMA positions of each of the DMA engines to the buffer in main memory periodically typically once frame . Software can use this value to know what data in memory is valid data. The controller must guarantee that the values in the DMA Position Buffer that the software can read represent positions in the stream for which valid data exists in the Stream s DMA buffer. This has particular relevance in systems which support isochronous transfer the stream positions in the software visible memory buffer must represent stream data which has reached the Global Observation point.

3	0	FIFO_ERROR_INTERRUPT_ENABLE
2	0	INTERRUPT_ON_COMPLETION_ENABLE
1	0	STREAM_RUN
0	0	STREAM_RESET

Bit Range	Default & Access	Description
31:30	0h RO	**RESERVED1:** reserved
29	0h RO	**FIFO_READY:** For input streams the controller hardware will set this bit to 1 when a valid descriptor is loaded and the engine is ready for the RUN bit to be set.
28	0h RW	**DESCRIPTOR_ERROR:** Indicates that a serious error occurred during the fetch of a descriptor. This could be a result of a Master Abort a Parity or ECC error on the bus or any other error which renders the current Buffer Descriptor or Buffer Descriptor List useless. This error is treated as a fatal stream error as the stream cannot continue running. The RUN bit will be cleared and the stream will stop. Software may attempt to restart the stream engine after addressing the cause of the error and writing a 1 to this bit to clear it.
27	0h RW	**FIFO_ERROR:** Set when a FIFO error occurs. Bit is cleared by writing a 1 to this bit position. This bit is set even if an interrupt is not enabled. For an input stream this indicates a FIFO overrun occurring while the RUN bit is set. When this happens the FIFO pointers don t increment and the incoming data is not written into the FIFO thereby being lost.
26	0h RW	**BUFFER_COMPLETION_INTERRUPT_STATUS:** This bit is set to 1 by the hardware after the last sample of a buffer has been processed AND if the Interrupt on Completion IOC bit is set in the command byte of the buffer descriptor. It remains active until software clears it by writing a 1 to this bit position.
25:24	0h RO	**RESERVED2:** reserved

Bit Range	Default & Access	Description
23:20	0h RW	**STREAM_NUMBER:** This value reflects the Tag associated with the data being transferred on the link. When an input stream is detected on any of the SDIx signals that match this value the data samples are loaded into the FIFO associated with this descriptor. Note that while a single SDIx input may contain data from more than one stream number two different SDIx inputs may not be configured with the same stream number. 0000 Reserved Indicates Unused 0001 Stream 1 1110 Stream 14 1111 Stream 15
19	0h RO	**BIDIRECTIONAL_DIRECTION_CONTROL:** This bit is only meaningful for Bidirectional streams. Therefore this bit is hardwired to 0.
18	01h RO	**TRAFFIC_PRIORITY:** Hardwired to 1 indicating that all streams will use VC1 if it is enabled throughout the PCI Express registers.
17:16	0h RO	**STRIPE_CONTROL:** This field is meaningless for input streams.
15:5	000h RO	**RESERVED0:** reserved
4	0h RW	**DESCRIPTOR_ERROR_INTERRUPT_ENABLE:** Controls whether an interrupt is generated when the Descriptor Error Status DESE bit is set.
3	0h RW	**FIFO_ERROR_INTERRUPT_ENABLE:** This bit controls whether the occurrence of a FIFO error overrun for input will cause an interrupt or not. If this bit is not set bit 3 in the Status register will be set but the interrupt will not occur. Either way the samples will be dropped.
2	0h RW	**INTERRUPT_ON_COMPLETION_ENABLE:** This bit controls whether or not an interrupt occurs when a buffer completes with the IOC bit set in its descriptor. If this bit is not set bit 2 in the Status register will be set but the interrupt will not occur.
1	0h RW	**STREAM_RUN:** When set to 1 the DMA engine associated with this input stream will be enabled to transfer data in the FIFO to main memory. The SSYNC bit must also be cleared in order for the DMA engine to run. When cleared to 0 the DMA engine associated with this input stream will be disabled. Hardware will report a 0 in this bit when the DMA engine is actually stopped. Software must read a 0 from this bit before modifying related control registers or restarting the DMA engine.
0	0h RW	**STREAM_RESET:** Writing a 1 causes the corresponding stream to be reset. The Stream Descriptor registers except the SRST bit itself and FIFO s for the corresponding stream are reset. After the stream hardware has completed sequencing into the reset state it will report a 1 in this bit. Software must read a 1 from this bit to verify that the stream is in reset. Writing a 0causes the corresponding stream to exit reset. When the stream hardware is ready to begin operation it will report a0 in this bit. Software must read a 0 from this bit before accessing any of the stream registers. The RUN bit must be cleared before SRST is asserted.

CYCLIC_BUFFER_LENGTH

Bit Range	Default & Access	Description
31:0	0h RW	**CYCLIC_BUFFER_LENGTH:** Indicates the number of bytes in the complete cyclic buffer. CBL must represent an integer number of samples. Link Position in Buffer LPIB will be reset when it reaches this value. Software may only write to this register after Global Reset Controller Reset or Stream Reset has occurred. This value should only be modified when the RUN bit is 0 . Once the RUN bit has been set to enable the engine software must not write to this register until after the next reset is asserted or transfers may be corrupted.

Bit Range	Default & Access	Description
31:30	0h RO	**RESERVED1:** reserved
29	0h RO	**FIFO_READY:** For input streams the controller hardware will set this bit to 1 when a valid descriptor is loaded and the engine is ready for the RUN bit to be set.
28	0h RW	**DESCRIPTOR_ERROR:** Indicates that a serious error occurred during the fetch of a descriptor. This could be a result of a Master Abort a Parity or ECC error on the bus or any other error which renders the current Buffer Descriptor or Buffer Descriptor List useless. This error is treated as a fatal stream error as the stream cannot continue running. The RUN bit will be cleared and the stream will stop. Software may attempt to restart the stream engine after addressing the cause of the error and writing a 1 to this bit to clear it.
27	0h RW	**FIFO_ERROR:** Set when a FIFO error occurs. Bit is cleared by writing a 1 to this bit position. This bit is set even if an interrupt is not enabled. For an input stream this indicates a FIFO overrun occurring while the RUN bit is set. When this happens the FIFO pointers don t increment and the incoming data is not written into the FIFO thereby being lost.
26	0h RW	**BUFFER_COMPLETION_INTERRUPT_STATUS:** This bit is set to 1 by the hardware after the last sample of a buffer has been processed AND if the Interrupt on Completion IOC bit is set in the command byte of the buffer descriptor. It remains active until software clears it by writing a 1 to this bit position.
25:24	0h RO	**RESERVED2:** reserved
23:20	0h RW	**STREAM_NUMBER:** This value reflects the Tag associated with the data being transferred on the link. When an input stream is detected on any of the SDIx signals that match this value the data samples are loaded into the FIFO associated with this descriptor. Note that while a single SDIx input may contain data from more than one stream number two different SDIx inputs may not be configured with the same stream number. 0000 Reserved Indicates Unused 0001 Stream 1 1110 Stream 14 1111 Stream 15
19	0h RO	**BIDIRECTIONAL_DIRECTION_CONTROL:** This bit is only meaningful for Bidirectional streams. Therefore this bit is hardwired to 0.
18	01h RO	**TRAFFIC_PRIORITY:** Hardwired to 1 indicating that all streams will use VC1 if it is enabled throughout the PCI Express registers.
17:16	0h RO	**STRIPE_CONTROL:** This field is meaningless for input streams.

Bit Range	Default & Access	Description
15:5	000h RO	**RESERVED0:** reserved
4	0h RW	**DESCRIPTOR_ERROR_INTERRUPT_ENABLE:** Controls whether an interrupt is generated when the Descriptor Error Status DESE bit is set.
3	0h RW	**FIFO_ERROR_INTERRUPT_ENABLE:** This bit controls whether the occurrence of a FIFO error overrun for input will cause an interrupt or not. If this bit is not set bit 3 in the Status register will be set but the interrupt will not occur. Either way the samples will be dropped.
2	0h RW	**INTERRUPT_ON_COMPLETION_ENABLE:** This bit controls whether or not an interrupt occurs when a buffer completes with the IOC bit set in its descriptor. If this bit is not set bit 2 in the Status register will be set but the interrupt will not occur.
1	0h RW	**STREAM_RUN:** When set to 1 the DMA engine associated with this input stream will be enabled to transfer data in the FIFO to main memory. The SSYNC bit must also be cleared in order for the DMA engine to run. When cleared to 0 the DMA engine associated with this input stream will be disabled. Hardware will report a 0 in this bit when the DMA engine is actually stopped. Software must read a 0 from this bit before modifying related control registers or restarting the DMA engine.
0	0h RW	**STREAM_RESET:** Writing a 1 causes the corresponding stream to be reset. The Stream Descriptor registers except the SRST bit itself and FIFO s for the corresponding stream are reset. After the stream hardware has completed sequencing into the reset state it will report a 1 in this bit. Software must read a 1 from this bit to verify that the stream is in reset. Writing a 0causes the corresponding stream to exit reset. When the stream hardware is ready to begin operation it will report a0 in this bit. Software must read a 0 from this bit before accessing any of the stream registers. The RUN bit must be cleared before SRST is asserted.

This error is treated as a fatal stream error as the stream cannot continue running. The RUN bit will be cleared and the stream will stop. Software may attempt to restart the stream engine after addressing the cause of the error and writing a 1 to this bit to clear it.
27	0h RW	**FIFO_ERROR:** Set when a FIFO error occurs. Bit is cleared by writing a 1 to this bit position. This bit is set even if an interrupt is not enabled. For an input stream this indicates a FIFO overrun occurring while the RUN bit is set. When this happens the FIFO pointers don t increment and the incoming data is not written into the FIFO thereby being lost.
26	0h RW	**BUFFER_COMPLETION_INTERRUPT_STATUS:** This bit is set to 1 by the hardware after the last sample of a buffer has been processed AND if the Interrupt on Completion IOC bit is set in the command byte of the buffer descriptor. It remains active until software clears it by writing a 1 to this bit position.
25:24	0h RO	**RESERVED2:** reserved

Bit Range	Default & Access	Description
23:20	0h RW	**STREAM_NUMBER:** This value reflects the Tag associated with the data being transferred on the link. When an input stream is detected on any of the SDIx signals that match this value the data samples are loaded into the FIFO associated with this descriptor. Note that while a single SDIx input may contain data from more than one stream number two different SDIx inputs may not be configured with the same stream number. 0000 Reserved Indicates Unused 0001 Stream 1 1110 Stream 14 1111 Stream 15
19	0h RO	**BIDIRECTIONAL_DIRECTION_CONTROL:** This bit is only meaningful for Bidirectional streams. Therefore this bit is hardwired to 0.
18	01h RO	**TRAFFIC_PRIORITY:** Hardwired to 1 indicating that all streams will use VC1 if it is enabled throughout the PCI Express registers.
17:16	0h RO	**STRIPE_CONTROL:** This field is meaningless for input streams.
15:5	000h RO	**RESERVED0:** reserved
4	0h RW	**DESCRIPTOR_ERROR_INTERRUPT_ENABLE:** Controls whether an interrupt is generated when the Descriptor Error Status DESE bit is set.
3	0h RW	**FIFO_ERROR_INTERRUPT_ENABLE:** This bit controls whether the occurrence of a FIFO error overrun for input will cause an interrupt or not. If this bit is not set bit 3 in the Status register will be set but the interrupt will not occur. Either way the samples will be dropped.
2	0h RW	**INTERRUPT_ON_COMPLETION_ENABLE:** This bit controls whether or not an interrupt occurs when a buffer completes with the IOC bit set in its descriptor. If this bit is not set bit 2 in the Status register will be set but the interrupt will not occur.
1	0h RW	**STREAM_RUN:** When set to 1 the DMA engine associated with this input stream will be enabled to transfer data in the FIFO to main memory. The SSYNC bit must also be cleared in order for the DMA engine to run. When cleared to 0 the DMA engine associated with this input stream will be disabled. Hardware will report a 0 in this bit when the DMA engine is actually stopped. Software must read a 0 from this bit before modifying related control registers or restarting the DMA engine.
0	0h RW	**STREAM_RESET:** Writing a 1 causes the corresponding stream to be reset. The Stream Descriptor registers except the SRST bit itself and FIFO s for the corresponding stream are reset. After the stream hardware has completed sequencing into the reset state it will report a 1 in this bit. Software must read a 1 from this bit to verify that the stream is in reset. Writing a 0causes the corresponding stream to exit reset. When the stream hardware is ready to begin operation it will report a0 in this bit. Software must read a 0 from this bit before accessing any of the stream registers. The RUN bit must be cleared before SRST is asserted.

1	0h RW	**STREAM_RUN:** When set to 1 the DMA engine associated with this output stream will be enabled to transfer data in the main memory to FIFO. The SSYNC bit must also be cleared in order for the DMA engine to run. For output streams the cadence generator is reset whenever the RUN bit is set. When cleared to 0 the DMA engine associated with this output stream will be disabled. Hardware will report a 0 in this bit when the DMA engine is actually stopped. Software must read a 0 from this bit before modifying related control registers or restarting the DMA engine.

Field	BUFFER_DESCRIPTOR_LIST_LOWER_BASE_ADDRESS	RESERVED0	PROTECT

Bit Range	Default & Access	Description
31:7	0h RW	**BUFFER_DESCRIPTOR_LIST_LOWER_BASE_ADDRESS:** Lower address of the Buffer Descriptor List. This value should only be modified when the RUN bit is 0 or DMA transfers may be corrupted. Intel Reserved comment This field becomes WO and 0 s will be read when the Protect bit is set to 1.
6:1	00h RO	**RESERVED0:** reserved
0	0h RW	**PROTECT:** When this bit is set to 1 bits 31 7 0 of this register are WO and will return 0 s when read. When this bit is cleared to 0 bits 31 7 0 are RW. Note that this bit can only be changed when all four bytes of this register are written in a single write operation. If less than four bytes are written this bit retains its previous value. This bit is Intel Reserved.

4	DESCRIPTOR_ERROR_INTERRUPT_ENABLE
3	FIFO_ERROR_INTERRUPT_ENABLE
2	INTERRUPT_ON_COMPLETION_ENABLE

0	STREAM_RESET

Bit Range	Default & Access	Description
31:30	0h RO	**RESERVED1:** reserved
29	0h RO	**FIFO_READY:** For output streams the controller hardware will set this bit to a 1 while the output DMA FIFO contains enough data to maintain the stream on then link. This bit defaults to 0 on reset because the FIFO is cleared on a reset.
28	0h RW	**DESCRIPTOR_ERROR:** Indicates that a serious error occurred during the fetch of a descriptor. This could be a result of a Master Abort a Parity or ECC error on the bus or any other error which renders the current Buffer Descriptor or Buffer Descriptor List useless. This error is treated as a fatal stream error as the stream cannot continue running. The RUN bit will be cleared and the stream will stop. Software may attempt to restart the stream engine after addressing the cause of the error and writing a 1 to this bit to clear it.
27	0h RW	**FIFO_ERROR:** Set when a FIFO error occurs. Bit is cleared by writing a 1 to this bit position. This bit is set even if an interrupt is not enabled. For an output stream this indicates a FIFO under run when there are still buffers to send. The hardware should not transmit anything on the link for the associated stream if there is not valid data to send.
26	0h RW	**BUFFER_COMPLETION_INTERRUPT_STATUS:** This bit is set to 1 by the hardware after the last sample of a buffer has been processed AND if the Interrupt on Completion IOC bit is set in the command byte of the buffer descriptor. It remains active until software clears it by writing a 1 to this bit position.
25:24	0h RO	**RESERVED2:** reserved

Bit Range	Default & Access	Description
23:20	0h RW	**STREAM_NUMBER:** This value reflects the Tag associated with the data being transferred on the link. When data controlled by this descriptor is sent out over the link it will have this stream number encoded on the SYNC signal. 0000 Reserved Indicates Unused 0001 Stream 1 1110 Stream 14 1111 Stream 15
19	0h RO	**BIDIRECTIONAL_DIRECTION_CONTROL:** This bit is only meaningful for Bidirectional streams. Therefore this bit is hardwired to 0.
18	01h RO	**TRAFFIC_PRIORITY:** Hardwired to 1 indicating that all streams will use VC1 if it is enabled throughout the PCI Express registers.
17:16	0h RO	**STRIPE_CONTROL:** For output streams it controls the number of SDO signals to stripe data across. Only one SDO is supported in the HD Audio controller. Therefore it is hardwired to 0 s.
15:5	000h RO	**RESERVED0:** reserved
4	0h RW	**DESCRIPTOR_ERROR_INTERRUPT_ENABLE:** Controls whether an interrupt is generated when the Descriptor Error Status DESE bit is set.
3	0h RW	**FIFO_ERROR_INTERRUPT_ENABLE:** This bit controls whether the occurrence of a FIFO error under run for output will cause an interrupt or not. If this bit is not set bit 3 in the Status register will be set but the interrupt will not occur. Either way the samples will be dropped.
2	0h RW	**INTERRUPT_ON_COMPLETION_ENABLE:** This bit controls whether or not an interrupt occurs when a buffer completes with the IOC bit set in its descriptor. If this bit is not set bit 2 in the Status register will be set but the interrupt will not occur.
1	0h RW	**STREAM_RUN:** When set to 1 the DMA engine associated with this output stream will be enabled to transfer data in the main memory to FIFO. The SSYNC bit must also be cleared in order for the DMA engine to run. For output streams the cadence generator is reset whenever the RUN bit is set. When cleared to 0 the DMA engine associated with this output stream will be disabled. Hardware will report a 0 in this bit when the DMA engine is actually stopped. Software must read a 0 from this bit before modifying related control registers or restarting the DMA engine.
0	0h RW	**STREAM_RESET:** Writing a 1 causes the corresponding stream to be reset. The Stream Descriptor registers except the SRST bit itself and FIFO s for the corresponding stream are reset. After the stream hardware has completed sequencing into the reset state it will report a 1 in this bit. Software must read a 1 from this bit to verify that the stream is in reset. Writing a 0causes the corresponding stream to exit reset. When the stream hardware is ready to begin operation it will report a0 in this bit. Software must read a 0 from this bit before accessing any of the stream registers. The RUN bit must be cleared before SRST is asserted.

FIFO_SIZE															

Bit Range	Default & Access	Description
15:0	00h RW	**FIFO_SIZE:** Indicates the maximum number of bytes that could be fetched by the controller at one time. This is the maximum number of bytes that may have been DMA d into memory but not yet transmitted on the link and is also the maximum possible value that the PICB count will increase by at one time. The FIFO size is calculated based on factors including the stream format programmed in OSD2FMT register. As the default value is zero, SW must write to the OSD2FMT register to kick of the FIFO size calculation and read back to find out the HW allocated FIFO size.

Bit Range	Default & Access	Description
31:30	0h RO	**RESERVED1:** reserved
29	0h RO	**FIFO_READY:** For output streams the controller hardware will set this bit to a 1 while the output DMA FIFO contains enough data to maintain the stream on then link. This bit defaults to 0 on reset because the FIFO is cleared on a reset.
28	0h RW	**DESCRIPTOR_ERROR:** Indicates that a serious error occurred during the fetch of a descriptor. This could be a result of a Master Abort a Parity or ECC error on the bus or any other error which renders the current Buffer Descriptor or Buffer Descriptor List useless. This error is treated as a fatal stream error as the stream cannot continue running. The RUN bit will be cleared and the stream will stop. Software may attempt to restart the stream engine after addressing the cause of the error and writing a 1 to this bit to clear it.
27	0h RW	**FIFO_ERROR:** Set when a FIFO error occurs. Bit is cleared by writing a 1 to this bit position. This bit is set even if an interrupt is not enabled. For an output stream this indicates a FIFO under run when there are still buffers to send. The hardware should not transmit anything on the link for the associated stream if there is not valid data to send.
26	0h RW	**BUFFER_COMPLETION_INTERRUPT_STATUS:** This bit is set to 1 by the hardware after the last sample of a buffer has been processed AND if the Interrupt on Completion IOC bit is set in the command byte of the buffer descriptor. It remains active until software clears it by writing a 1 to this bit position.
25:24	0h RO	**RESERVED2:** reserved
23:20	0h RW	**STREAM_NUMBER:** This value reflects the Tag associated with the data being transferred on the link. When data controlled by this descriptor is sent out over the link it will have this stream number encoded on the SYNC signal. 0000 Reserved Indicates Unused 0001 Stream 1 1110 Stream 14 1111 Stream 15
19	0h RO	**BIDIRECTIONAL_DIRECTION_CONTROL:** This bit is only meaningful for Bidirectional streams. Therefore this bit is hardwired to 0.
18	01h RO	**TRAFFIC_PRIORITY:** Hardwired to 1 indicating that all streams will use VC1 if it is enabled throughout the PCI Express registers.
17:16	0h RO	**STRIPE_CONTROL:** For output streams it controls the number of SDO signals to stripe data across. Only one SDO is supported in the HD Audio controller. Therefore it is hardwired to 0 s.
15:5	000h RO	**RESERVED0:** reserved

Bit Range	Default & Access	Description
4	0h RW	**DESCRIPTOR_ERROR_INTERRUPT_ENABLE:** Controls whether an interrupt is generated when the Descriptor Error Status DESE bit is set.
3	0h RW	**FIFO_ERROR_INTERRUPT_ENABLE:** This bit controls whether the occurrence of a FIFO error under run for output will cause an interrupt or not. If this bit is not set bit 3 in the Status register will be set but the interrupt will not occur. Either way the samples will be dropped.
2	0h RW	**INTERRUPT_ON_COMPLETION_ENABLE:** This bit controls whether or not an interrupt occurs when a buffer completes with the IOC bit set in its descriptor. If this bit is not set bit 2 in the Status register will be set but the interrupt will not occur.
1	0h RW	**STREAM_RUN:** When set to 1 the DMA engine associated with this output stream will be enabled to transfer data in the main memory to FIFO. The SSYNC bit must also be cleared in order for the DMA engine to run. For output streams the cadence generator is reset whenever the RUN bit is set. When cleared to 0 the DMA engine associated with this output stream will be disabled. Hardware will report a 0 in this bit when the DMA engine is actually stopped. Software must read a 0 from this bit before modifying related control registers or restarting the DMA engine.
0	0h RW	**STREAM_RESET:** Writing a 1 causes the corresponding stream to be reset. The Stream Descriptor registers except the SRST bit itself and FIFO s for the corresponding stream are reset. After the stream hardware has completed sequencing into the reset state it will report a 1 in this bit. Software must read a 1 from this bit to verify that the stream is in reset. Writing a 0causes the corresponding stream to exit reset. When the stream hardware is ready to begin operation it will report a0 in this bit. Software must read a 0 from this bit before accessing any of the stream registers. The RUN bit must be cleared before SRST is asserted.

CYCLIC_BUFFER_LENGTH

Bit Range	Default & Access	Description
31:0	0h RW	**CYCLIC_BUFFER_LENGTH:** Indicates the number of bytes in the complete cyclic buffer. CBL must represent an integer number of samples. Link Position in Buffer LPIB will be reset when it reaches this value. Software may only write to this register after Global Reset Controller Reset or Stream Reset has occurred. This value should only be modified when the RUN bit is 0 . Once the RUN bit has been set to enable the engine software must not write to this register until after the next reset is asserted or transfers may be corrupted.

21 Low Power Engine (LPE) for Audio (I^2S)

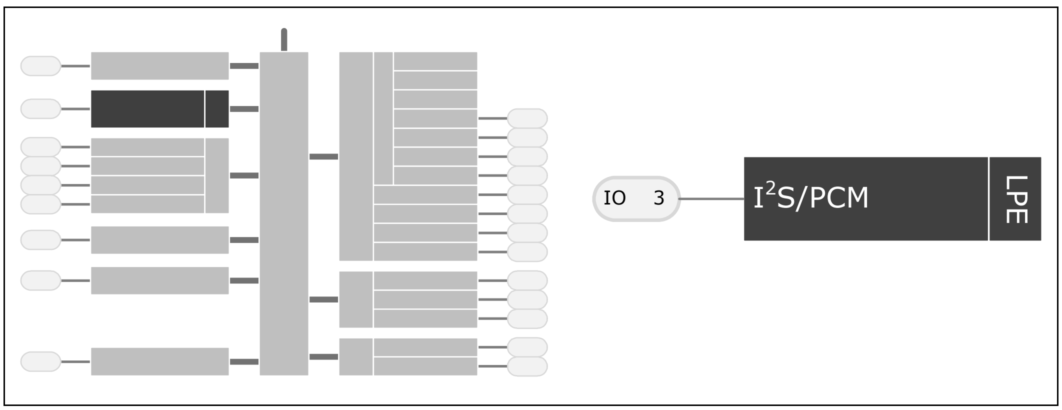
The Low Power Engine for Audio provides acceleration for common audio and voice functions. The voice and audio engine provides a mechanism for rendering audio and voice streams and tones from the operating system, applications to an audio or voice codec, and ultimately to the speaker, headphones, or Bluetooth headsets.

Audio streams in the SoC can be encoded and decoded by the Low Power Engine (LPE) in the Audio subsystem.

LPE Audio provides three external I^2S audio interfaces.

Note: LPE_I2S[1:0] are multiplexed on the same balls as High Definition Audio.

Note: When LPE is active, the High Definition Audio functionality is disabled.



21.1 Signal Descriptions

See Chapter 2, "Physical Interfaces" for additional details.

The signal description table has the following headings:

- **Signal Name:** The name of the signal/pin
- **Direction**: The buffer direction can be either input, output, or I/O (bidirectional)
- **Platform Power**: The reference power plane.
- **Description**: A brief explanation of the signal's function

21.2 Features

The LPE Audio Subsystem consists of the following:

- Integrated, power-efficient 32-bit architecture core with 24-bit audio processing instructions
- Core processing speeds up to 343 MHz
- Closely Coupled Memories (CCMs)
  - 80KB Instruction RAM
  - 160KB Data RAM
  - 48KB Instruction Cache
  - 96KB Data Cache
- Very low-power consumption coupled with high-fidelity 24-bit audio
- Dual-issue, static, super-scalar VLIW processing engine
- Mode-less switching between 16-, 24-, and 64-bit dual-issue instructions
- Dual MACs which can operate with 32 x 16-bit and/or 24 x 24-bit operands
- Inter-Process Communication (IPC) mechanism to communicate with the SoC Processor Core including 4KB mailbox memory
- Flexible audio interfaces include three SSPs with I^{2}S port functionality for I-directional audio transfers
  - I^{2}S mode supports PCM payloads
  - Frame counters for all I^{2}S ports
- High Performance DMA
  - DMA IP to support multiple outstanding transactions
  - Interleaved scatter-gather support for Audio DMA transfers
- Clock switching logic including new frequency increments

- External timer function with an always running clock.

The LPE core runs at a peak clock frequency of 343 MHz and has dedicated on-chip program and data memories and caches. The LPE core can access shared SRAM blocks, and external DRAM through OCP fabric. It communicates with audio peripherals using the audio sub-fabric, and employs Inter-Processor Communication (IPC) mechanism to communicate with the SoC Processor Core.

The Audio subsystem includes two OCP-based DMA engines. These DMA engines support single and multi-block transfers. They can be configured to transfer data between DRAM and audio CCMs or transfer data between CCMs and the audio peripheral interfaces

All these interfaces are peripherals in the Audio subsystem. LPE, LPE DMA, or the SoC processor core may access the peripherals during normal operation. The PMC may access all peripherals during specific tasks such as at boot time or during power state changes.A complete audio solution based on an internal audio processing engine which includes several I^2S-based output ports.

The audio core used is a dedicated audio DSP core designed specifically for audio processing (decoding, post-processing, mixing, etc.)

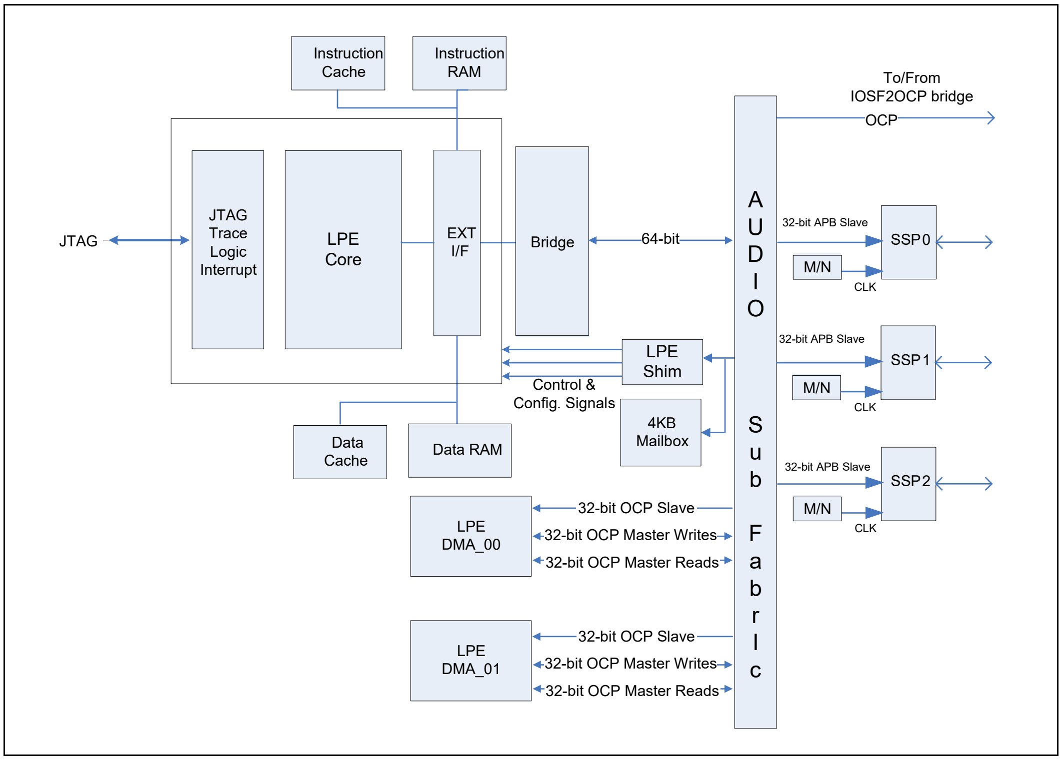
Note: LPE requires systems with more than 512MB memory. This is required since the LPE firmware must reside at a stolen memory location on 512MB boundaries below 3 GiB. The LPE firmware itself is ~1MB, and is reserved by BIOS for LPE use.

21.3 Detailed Block Level Description

21.3.1 LPE Core

The LPE core in the SoC runs at maximum frequency of 343 MHz and interfaces with the rest of the SoC system through the OCP bus. It is one of the masters on the Audio Sub-Fabric The SoC Processor Core and LPE DMA engines are the other masters on the fabric. The following figure shows the LPE core and its interfaces.

Figure 106.Audio Cluster Block Diagram

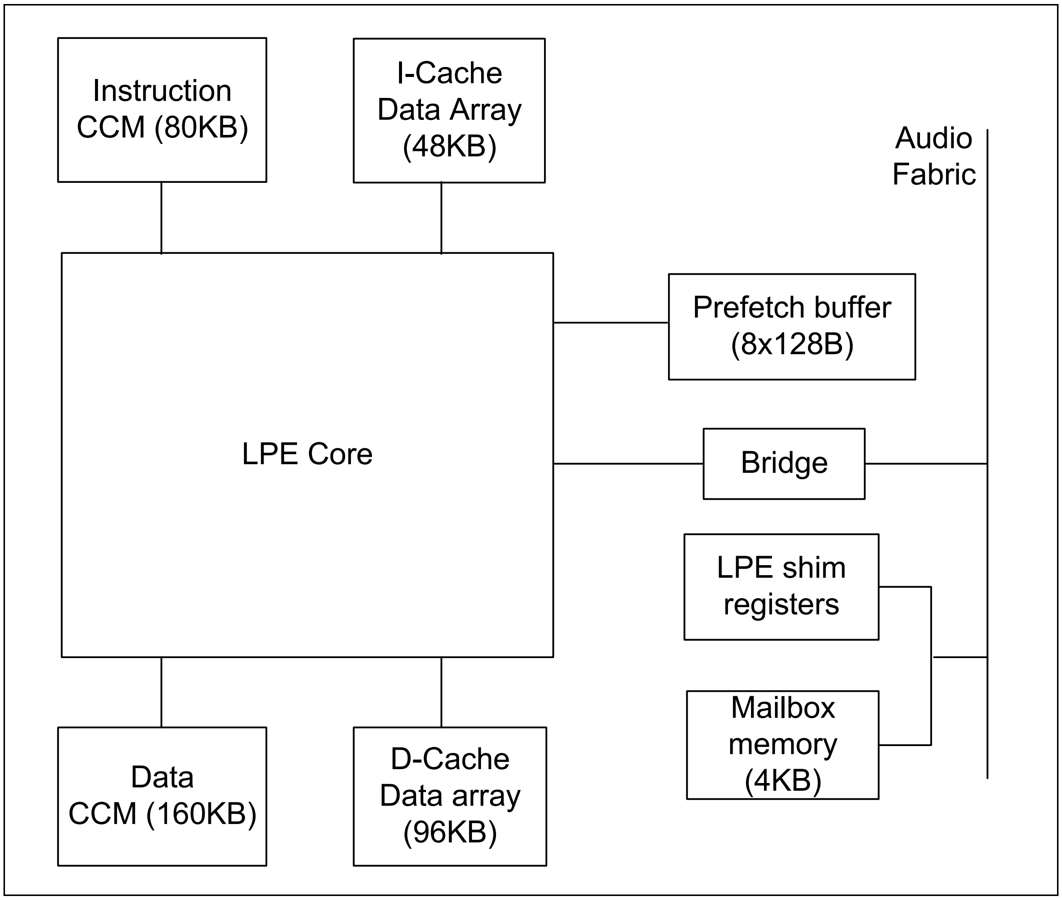


The main DSP hardware is a two-multiplier, multiply/accumulate unit, a register file LPE_PR to hold pairs of 24-bit data items, a register file LPE-OR to hold 56-bit accumulator values, an arithmetic/logic unit to operate on the LPE_PR and LPE_OR values, and a shift unit to operate on the LPE_PR and LPE_OR values. The multiply/accumulate unit also supports multiplication of 32-bit values from LPE_OR registers by 16-bit values from LPE_PR registers, with the 48-bit result written or accumulated in the LPE_OR register. The instructions for the DSP subsystems are built from operations that are divided into two sets: the slot 0 set and the slot 1 set. In each execution cycle, zero or one operations from each set can be executed independently according to the static bundling expressed in the machine code.

21.3.2 Memory Architecture

The LPE core is configured to use local memory and local caches. It has 80KB of Instruction Closely Coupled Memory (CCM), 160KB of Data CCM, 48KB of Instruction Cache and 96KB of Data Cache. The LPE core also has access to 4KB of mailbox memory and external DRAM.

Figure 107. Memory Connections for LPE



21.3.3 Instruction Closely Coupled Memory (CCM)

Instruction CCM for the core is used for loading commonly used routines as well as time-critical processing. Examples of time critical processing are acoustic echo cancellation and noise cancellation during voice calls.

Instruction CCM is initialized after reset by an external DMA controller. Runtime update of instruction CCM can be done either using explicit instructions or using an external DMA controller with inbound access.

21.3.4 Data Closely Coupled Memory (CCM)

Data CCM can be initialized after reset by an external DMA controller using inbound access. Runtime update of data CCM can be done either using stores to Data CCM or using an external DMA controller with inbound access.

21.3.5 Mailbox Memory and Data Exchange

The mailbox memory is a shared memory region in LPE address space that is accessible by the SOC Processor Core, PMC, and LPE. It is used when Doorbell registers cannot hold all the information that one processor wishes to communicate to the other. A typical example of such data blocks are audio stream related parameters when starting a new stream. The structures of data communicated through the mailbox are not defined in hardware so that software may partition the mailbox memory in any desired way and create any meaningful structures required.

21.4 Software Implementation Considerations

21.4.1 SoC Processor Core Cache Coherence

Traffic generated by the LPE core is considered non-cacheable and non-coherent with respect to the SoC Processor Core cache. DMA traffic is considered cacheable and checked for coherency with the SoC Processor Core cache.

Implications of this implementation are as follows:

- All code and tables for the LPE core need to be explicitly flushed from the SoC Processor Core cache if they are ever accessed.
- If the LPE core directly accesses data buffers in system DDR, the driver must explicitly flush the buffer from the SoC Processor Core cache
- If DMA accesses data buffers from system DRAM, the driver need not flush the data buffer from the SoC Processor Core cache.

21.4.2 Interrupts

21.4.2.1 LPE Peripheral Interrupts

Each of the LPE peripherals generates its own interrupts. SSP0, SSP1, and SSP2 have one interrupt each. Each of the DMA channels have individual interrupt lines. These interrupts are connected to the LPE core through the PISR register. The same interrupts are routed to IOAPIC through the ISRX register. The LPE core and SoC Processor Core have individual masks to enable these interrupts.

21.4.2.2 Interrupts Between SoC Processor Core and the LPE

The interrupts between the SoC Processor Core and the LPE are handled through the inter-processor communication registers. Whenever the SoC Processor Core writes to the IPCX communication register an interrupt is generated to the LPE. The LPE firmware sees there is a message waiting from the SoC Processor Core, and reads the IPCX register for the data. This data is a pre-configured message, where the message structure has been decided beforehand between the SoC Processor Core and the LPE. Similarly we have the IPCD register for the communication between the LPE and SoC Processor Core. Once the LPE writes to the IPCD register, an interrupt should be generated for the SoC Processor Core and the SoC Processor Core should read the message from the IPCD register and act accordingly. From a software viewpoint, the mechanism remains the same as before. From a hardware view point, the interrupt to IA-32 gets routed by means of the IOAPIC block. The IPC from Audio to SoC Processor Core gets a dedicated interrupt line to the IOAPIC.

21.4.2.3 Interrupts between PMC and LPE

The interrupts between PMC and LPE are also handled using Inter Process Communication registers.

21.4.3 Power Management Options for the LPE Core

- WAITI
  - Allows the LPE core to suspend operation until an interrupt occurs by executing the optional WAITI instruction.
- External Run/Stall Control Signal
  - This processor input allows external logic to stall large portions of the LPE pipeline by shutting off the clock to much of the processor's logic to reduce operating power when the LPE computational capabilities are not immediately needed by the system.

Note: Using the WAITI instruction to power down the processor will save more power than use of the external run/stall signal because the WAITI instruction disables more of the LPE’s internal clocks.

21.4.4 External Timer

This timer always runs from SSP clock (before M/N divider) at 19.2/25MHz. The timer starts running once the run bit (refer to the External timer register definition for details) is set and the clear bit is cleared.

The timer generates an Interrupt pulse when the counter value matches the "match" value. The interrupt does not get generated if the match value is set to "0". The timer runs in free running mode and rolls over after all 32 bits have become all 1's.

The timer continues to run as long as the run bit is set. Once the run bit is cleared the timer holds the current value. The clear bit needs to be set to restart the timer from "0".

21.5 Clocks

21.5.1 Clock Frequencies

Table 227 shows the clock frequency options for the Audio functional blocks.

Table 227. Clock Frequencies

Clock	Frequency	Notes
Audio core	25/50/100/200/267/343 MHz	Audio input clock trunk. CCU drives one of several frequencies as noted.

SSP0 Clock	Fabric side: 25/50 MHz Link side: Up to 19.2/25 MHz	SSP0 clock domains
SSP1 Clock	Fabric side: 25/50 MHz Link side: Up to 19.2/25 MHz	SSP1 clock domains
SSP2 Clock	Fabric side: 25/50 MHz Link side: Up to 19.2/25 MHz	SSP2 clock domains

21.5.2 50 MHz Clock for LPE

50 MHz, the 2X OSC clock, is added to increase MIPS for low power MP3 mode. This frequency will be supplied by the clock doubler internal to the SoC's Clock Control Unit.

21.5.3 Cache and CCM Clocking

Data CCM, Data cache, Instruction CCM, and Instruction Cache run off of the LPE clock. These memories are in a single clock domain.

Note: All Data CCM and Instruction CCM run in the same clock domain.

21.5.4 SSP Clocking

SSP could be used as either clock masters or clock slaves. Consequently, theses IP have dual clock domains.

The first clock domain is clocked from an internal clock (e.g., fabric clock) and is used for generic logic like interrupt generation and register access.

The second clock domain drives the serial shift register (either driven internally or externally). When driven internally, this clock can be sourced from XTAL clock 25 MHz or PLL 19.2 MHz. These clocks are then divided down within the serial interface IP to generate the final bit clock for the interface.

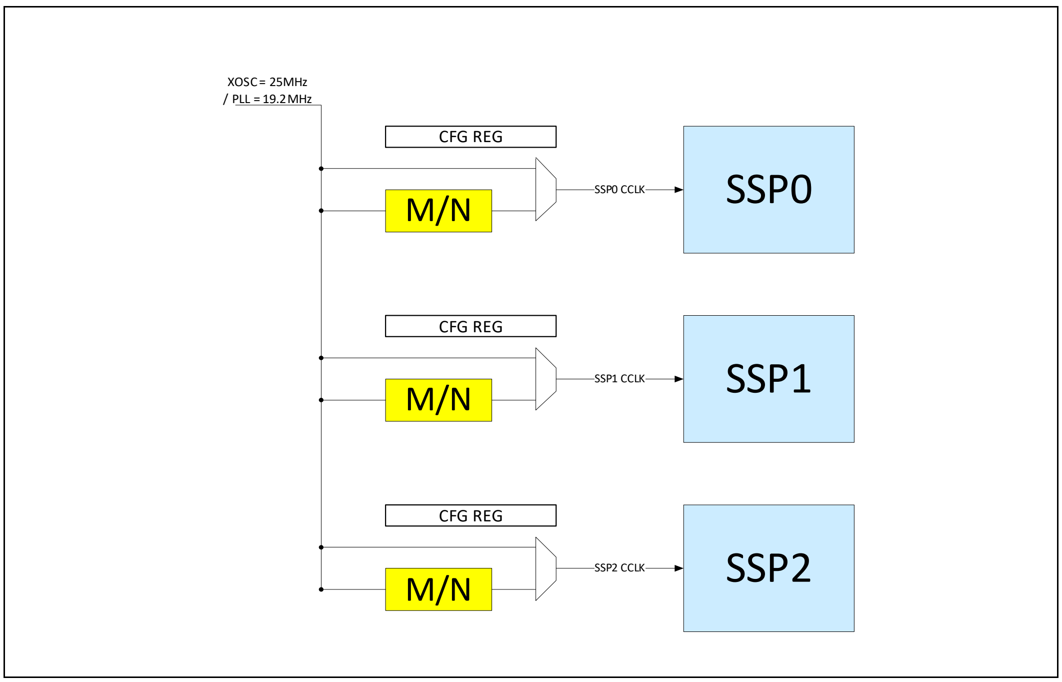
After power on, if the SSP input IO clock is in high state, first transition of the clock from high to low may be missing due to the Soc clock gating logic.

Note: "Frame Master" mode cannot be used when operating as clock slave and "Frame Slave" mode cannot be used when operating as clock master.

21.5.5 M/N Divider

LPE SSP in master mode uses the SSP CCLK to drive the serial clock. It has very limited option to divide CCLK. An M/N divider is added between the 19.2/25 MHz clock (XOSC) from CCU to each SSP CCLK input as shown in following diagram:

Figure 108.SSP CCLK Structure



Note: The maximum SSP CCLK frequency is listed in Table 132.

The LPE M/N divider is designed to produce a clock signal for the SSP block used in master mode. The divider is based on a generic NOM/DENOM divider. The supplied Master clock is 25 MHz (XTAL) or 19.2 MHz (LPPLL), but usually be used by the 25 MHz clock.

This mechanism is good for a wide spectrum of generated clocks. Two registers must be configured to get the target SSP clock. The values for the Nominator and Denominator registers are the smallest divider of:

$$\frac{Nominator}{Denominator} = \frac{Source\_clock}{Target\_clock}$$

21.5.5.1 Example

If we want to generate 17.64 MHz (=400x44.1 KHz) output clock out of 25 MHz clock, we need to program "NOM = 441" and "DENOM = 625":

17.64 MHz = (441/625) x 25 MHz

In general the M over N can generate fractional devisor that could be used for generating the required clocks for Audio codec. Table 228 describes some configuration options of this generic divider:

Table 228. M/N Values, Examples

Source Clock Frequency	Requested Clock	M/N Value
25 MHz	48 KHz	6/3125
	48K x 24 = 1.152 MHz	1152/25000
	48K x32 = 1.536 MHz	1536/25000
	48K x 64 = 3.072 MHz	3072/25000
	44.1 KHz	441/250000
	48K x 400 = 19.2 MHz	96/125
	44.1K x 400 = 17.64 MHz	441/625

21.5.5.2 Accuracy and Jitter

The output of the M/N is equal to the desired clock in average with Jitter of 20nTXE for 25 MHz input clock.

21.5.5.3 Configuration

Following configurable fields per M/N divider/SSP are in LPE shim registers:

Table 229. M/N Configurable Fields

Field	Width	Description
Bypass	1 bit	When set M/N divider is bypass. Clock from CCU is connected directly to SSP CCLK
EN	1 bit	Enable the divider
Update	1 bit	Update divider parameters
M Value	20 bits	Nominator value
N Value	20 bits	Denominator value

21.6 SSP (I^2S)

The SoC audio subsystem consists of the LPE Audio Engine and three Synchronous Serial Protocol (SSP) ports. These ports are used in PCM mode and enable simultaneous support of voice and audio streams over I^2S. The SoC audio subsystem also includes two DMA controllers dedicated to the LPE. The LPE DMA controllers are used for transferring data between external memory and CCMs, between CCMs and the SSP ports, and between CCMs. All peripheral ports can operate simultaneously.

21.6.1 Introduction

The Enhanced SSP Serial Ports are full-duplex synchronous serial interfaces. They can connect to a variety of external analog-to-digital (A/D) converters, audio, and telecommunication codecs, and many other devices which use serial protocols for transferring data. Formats supported include National* Microwire, Texas Instruments* Synchronous Serial Protocol (SSP), Motorola* Serial Peripheral Interface (SPI) protocol and a flexible Programmable Serial Port protocol (PSP).

The Enhanced SSPs operate in master mode (the attached peripheral functions as a slave) or slave mode (the attached peripheral functions as a master), and support serial bit rates from 0 to 25 Mbps, dependent on the input clock. Serial data formats range from 4 to 32-bits in length. Two on-chip register blocks function as independent FIFOs for transmit and receive data.

FIFOs may be loaded or emptied by the system processor using single transfers or DMA burst transfers of up to the FIFO depth. Each 32-bit word from the bus fills one entry in a FIFO using the lower significant bits of a 32-bit word.

21.6.2 SSP Features

The SSP port features are:

- Inter-IC Sound (I^2S) protocols, are supported by programming the Programmable Serial Protocol (PSP).
- One FIFO for transmit data (TXFIFO) and a second, independent, FIFO for receive data (RXFIFO), where each FIFO is 16 samples deep x 32 bits wide
- Data sample sizes from 8, 16, 18 and 24bits

- 12.5 Mbps maximum serial bit-rate in both modes: master and slave.
- Clock master or slave mode operations
- Receive-without-transmit operation
- Network mode with up to eight time slots for PSP formats, and independent transmit/receive in any/all/none of the time slots.
- After updating SSP configuration, for example active slot count, the SSP will need to be disabled and enabled again. In other words, a SSP will not function correctly if a user changes the configuration setting on the fly.

21.6.3 Operation

Serial data is transferred between the LPE core or the SoC Processor Core and an external peripheral through FIFOs in one of the SSP ports. Data transfers between an SSP port and memory are initiated by either the LPE core or the SoC Processor Core using programmed I/O, or by DMA bursts. Although it is possible to initiate transfers directly from the SoC Processor Core, current driver design uses LPE for all PCM operations. Separate transmit and receive FIFOs and serial data paths permit simultaneous transfers in both directions to and from the external peripheral, depending on the protocols chosen.

Programmed I/O can transfer data between:

- The LPE core and the FIFO Data register for the TXFIFO
- The SoC Processor Core and the FIFO Data register for the TXFIFO
- The LPE core and the FIFO Data register for the RXFIFO
- The SoC Processor Core and the FIFO Data register for the RXFIFO
- The SoC Processor Core and the control or status registers
- The LPE core and the control or status registers

DMA bursts can transfer data between:

- Universal memory and the FIFO Data register for the TXFIFO
- Universal memory and the FIFO Data register for the RXFIFO
- Universal memory and the sequentially addressed control or status registers

21.6.4 LPE and DMA FIFO Access

The LPE or DMA access data through the Enhanced SSP Port’s Transmit and Receive FIFOs. An LPE access takes the form of programmed I/O, transferring one FIFO entry per access. LPE accesses would normally be triggered off of an SSSR Interrupt and must always be 32 bits wide. LPE Writes to the FIFOs are 32 bits wide, but the serializing logic will ignore all bits beyond the programmed FIFO data size (EDSS/DSS value). LPE Reads to the FIFOs are also 32 bits wide, but the Receive data written into the RX FIFO (from the RXD line) is stored with zeroes in the MSBs down to the programmed data size. The FIFOs can also be accessed by DMA bursts, which must be in multiples of 1, 2 or 4 bytes, depending upon the EDSS value, and must also transfer one FIFO entry per access. When the SSCR0.EDSS bit is set, DMA bursts must be in multiples of 4 bytes (the DMA must have the Enhanced SSP configured as a 32-bit peripheral).The DMA's width register must be at least the SSP data size programmed into the SSP control registers EDSS and DSS. The FIFO is seen as one 32-bit location by the processor. For Writes, the Enhanced SSP port takes the data from the Transmit FIFO, serializes it, and sends it over the serial wire (I2S[2:0]_DATAOUT) to the external peripheral. Receive data from the external peripheral (on I2S[2:0]_DATAIN) is converted to parallel words and stored in the Receive FIFO.

A programmable FIFO trigger threshold, when exceeded, generates an Interrupt or DMA service request that, if enabled, signals the CPU or DMA respectively to empty the Receive FIFO or to refill the Transmit FIFO.

The Transmit and Receive FIFOs are differentiated by whether the access is a Read or a Write transfer. Reads automatically target the Receive FIFO, while Writes will write data to the Transmit FIFO. From a memory-map perspective, they are at the same address. FIFOs are 16 samples deep by 32 bits wide. Each read or write is to 1 SSP sample.

21.6.5 Supported Formats

The SSP consists of four pins that are used to transfer data between the SoC and external Audio codecs, modems, or other peripherals. Although four serial-data formats exist, each has the same basic structure, and in all cases the following pins are used in the following manner:

- I2Sx_CLK—Defines the bit rate at which serial data is driven onto and sampled from the port
- I2Sx_FRM—Defines the boundaries of a basic data "unit," comprised of multiple serial bits
- I2Sx_DATAIN—The serial data path for transmitted data, from system to peripheral
- I2Sx_DATAOUT—The serial data path for received data, from peripheral to system

A data frame can contain from 4 to 32 bits, depending on the selected format. Serial data is transmitted most significant bit first. The Programmable Serial Protocol (PSP) format is used to implement I^2S.

Master and Slave modes are supported. When driven by the Enhanced SSP, the I2Sx_CLK only toggles during active transfers (not continuously) unless ECRA/ECRB functions are used. When the I2Sx_CLK is driven by another device, it is allowed to be either continuous or only driven during transfers, but certain restrictions on PSP parameters apply.

Normally, the serial clock (I2Sx_CLK), if driven by the Enhanced SSP Port, only toggles while an active data transfer is underway. There are several conditions, however, that may cause the clock to run continuously. If the Receive With Out Transmit mode is enabled by setting the SSCR1.RWOT bit to 1, the I2Sx_CLK will toggle regardless of whether Transmit data exists within the Transmit FIFO. The I2Sx_CLK will also toggle continuously if the Enhanced SSP is in Network mode, or if ECRA, or ECRB is enabled. At other times, I2Sx_CLK will be held in an inactiveI2Sx_FRM or idle state, as defined by the specified protocol under which it operates.

21.6.5.1 Programmable Serial Protocol (PSP)

There are many variations of the frame behavior for different codecs and protocol formats. To allow flexibility the PSP format allows I2Sx_FRM to be programmable in direction, delay, polarity, and width. Master and Slave modes are supported. PSP can be programmed to be either full or half duplex.

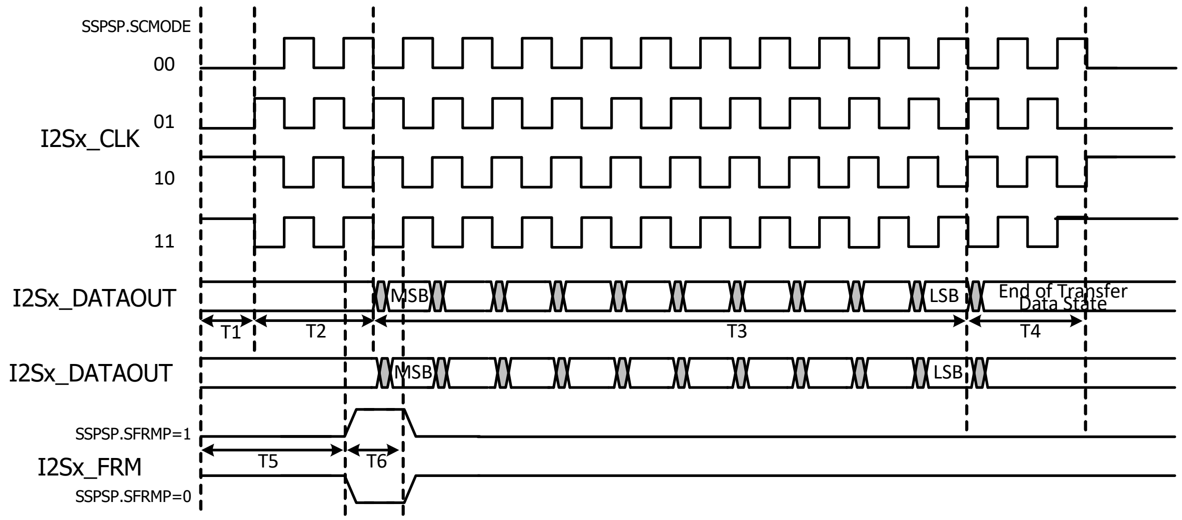
The I2Sx_CLK function behavior varies between each format. PSP lets programmers choose which edge of I2Sx_CLK to use for switching Transmit data, and for sampling Receive data. In addition, programmers can control the idle state for I2Sx_CLK and the number of active clocks that precede and follow the data transmission.

The PSP format provides programmability for several parameters that determine the transfer timings between data samples. There are four possible serial clock sub-modes, depending on the I2Sx_CLK edges selected for driving data and sampling received data, and the selection of idle state of the clock.

For the PSP format, the Idle and Disable modes of the I2Sx_DATAOUT, I2Sx_CLK, and I2Sx_FRM are programmable by means of the SSPSP.ETDS, SSPSP.SCMODE and SSPSP.SFRMP bits. When Transmit data is ready, the I2Sx_CLK will remain in its Idle state for the number of serial clock (I2Sx_CLK) clock periods programmed within the Start Delay (SSPSP.STRTDLY) field. I2Sx_CLK will then start toggling, I2Sx_DATAOUT will remain in the idle state for the number of cycles programmed within the Dummy Start (SSPSP.DMYSTRT) field. The I2Sx_FRM signal will be asserted after the number of half-clocks programmed in the SSPSP.SFRDLY field. The I2Sx_FRM signal will remain asserted for the number of clocks programmed within the SSPSP.SFRMWDTH then de-assert. Four to 32 bits can be transferred per frame. Once the last bit (LSB) is transferred, the I2Sx_CLK will continue toggling based off the Dummy Stop (SSPSP.DMYSTOP) field. I2Sx_DATAOUT either retains the last value transmitted or is forced to zero, depending on the value programmed within the End of Transfer Data State (SSPSP.ETDS) field, when the controller goes into Idle mode, unless the Enhanced SSP port is disabled or reset (which forces I2Sx_DATAOUT to zero).

With the assertion of I2Sx_FRM, Receive data is simultaneously driven from the peripheral on I2Sx_DATAIN, most significant bit first. Data transitions on I2Sx_CLK based on the Serial Clock Mode selected and is sampled by the controller on the opposite edge. When the Enhanced SSP is a master to the frame synch (I2Sx_FRM) and a slave to the clock (I2Sx_CLK), then at least three extra clocks (I2Sx_CLKs) will be needed at the beginning and end of each block of transfers to synchronize control signals from the APB clock domain into the SSP clock domain (a block of transfers is a group of back-to-back continuous transfers).

Figure 109.Programmable Serial Protocol Format



NOTE: When in PSP format, if the SSP is the master of the clock (I2Sx_CLK is an output) and the SSPSP.ETDS bit is cleared, the End of Transfer Data State for the I2Sx_DATAOUT line is 0. If the SSP is the master of the clock, and the SSPSP.ETDS bit is set, the I2Sx_DATAOUT line remains at the last bit transmitted (LSB). If the SSP is a slave to the clock (I2Sx_CLK is an input), and modes 1 or 3 are used, the ETDS can only change from the LSB if more clocks (I2Sx_CLK) are sent to the SSP (i.e., dummy stop clocks or slave clock is free running.

Table 230. Programmable Protocol Parameters

Symbol	Definition (Register.Bit Field)	Range	Units
	Serial Clock Mode (SSPSP.SCMODE)	(Drive, Sample, I2Sx_CLK Idle) 0 = Fall, Rise, Low 1 = Rise, Fall, Low 2 = Rise, Fall, High 3 = Fall, Rise, High	
	Serial Frame Polarity (SSPSP.SFRMP)	High or Low	
T1	Start Delay (SSPSP.STRTDLY)	0–7	Clock Period
T2	Dummy Start (SSPSP.DMYSTRT)	0–3	Clock Period
T3	Data Size (SSCRO.EDSS AND SSCRO.DSS)	4–32	Clock Period
T4	Dummy Stop (SSPSP.DMYSTOP)	0–3	Clock Period
T5	I2Sx_FRM Delay (SPSP.SFRMDLY)	0–88	Half Clock Period
T6	I2Sx_FRM Width (SSPSP.SFRMWDTH)	1–44	Clock Period
	End of Transfer Data State (SSPSP.ETDS)	Low or [bit 0]	

Note: The I2Sx_FRM Delay must not extend beyond the end of T4. I2Sx_FRM Width must be asserted for at least 1 I2Sx_CLK, and should be de-asserted before the end of the T4 cycle (for example, in terms of time, not bit values, (T5 + T6) <= (T1 + T2 + T3 + T4), 1<= T6 < (T2 + T3 + T4), and (T5 + T6) >= (T1 + 1) to ensure that I2Sx_FRM is asserted for at least 2 edges of the I2Sx_CLK). The T1 Start Delay value should be programmed to 0 when the I2Sx_CLK is enabled by either of the SSCR1.ECRA or SSCR1.ECRB bits. While the PSP can be programmed to generate the assertion of I2Sx_FRM during the middle of the data transfer (after the MSB was sent), the Enhanced SSP will not be able to receive data in Frame slave mode (SSCR1SFRMDIR = 1) if the assertion of Frame is not before the MSB is sent (i.e. T5 <= T2 if SSCR1.SFRMDIR =1). Transmit Data will transition from the "End of Transfer Data State" to the next MSB value upon the assertion of Frame. The Start Delay field should be programmed to 0 whenever I2Sx_CLK or I2Sx_FRM is configured as an input. Clock state is not defined between two active frame periods. Clock can be active or inactive between two active frame periods.

21.7 Programming Model

The CPU or DMA access data through the Enhanced SSP Port's Transmit and Receive FIFOs. A CPU access takes the form of programmed I/O, transferring one FIFO entry per access. CPU accesses would normally be triggered off of an SSSR Interrupt and must always be 32 bits wide. The CPU Writes to the FIFOs are 32 bits wide, but the serializing logic will ignore all bits beyond the programmed FIFO data size (EDSS/DSS value). CPU Reads to the FIFOs are also 32 bits wide, but the Receive data written into the RX FIFO (from the RXD line) is stored with zeroes in the MSBs down to the programmed data size. The FIFOs can also be accessed by DMA bursts, which must be in multiples of 1, 2, or 4 bytes, depending upon the EDSS value, and must also transfer one FIFO entry per access. When the SSCR0.EDSS bit is set, DMA bursts must be in multiples of 4 bytes (the DMA must have the Enhanced SSP configured as a 32-bit peripheral). The DMA DCMD.width register must be at least the SSP data size programmed into the SSP control registers EDSS and DSS. The FIFO is seen as one 32-bit location by the processor. For Writes, the Enhanced SSP port takes the data from the Transmit FIFO, serializes it, and sends it over the serial wire (I2Sx_DATAOUT) to the external peripheral. Receive data from the external peripheral (on I2Sx_DATAIN) is converted to parallel words and stored in the Receive FIFO.

A programmable FIFO trigger threshold, when exceeded, generates an Interrupt or DMA service request that, if enabled, signals the IA-32 CPU or DMA respectively to empty the Receive FIFO or to refill the Transmit FIFO. The Transmit and Receive FIFOs are differentiated by whether the access is a Read or a Write transfer. Reads automatically target the Receive FIFO, while Writes will write data to the Transmit FIFO. From a memory-map perspective, they are at the same address. Each read or write is 1 SSP sample.

21.7.1 PIO and DMA Programming Considerations

All CPU and DMA accesses transfer one FIFO entry per access. Data in the FIFOs is always stored with one 32-bit value per data sample, regardless of the format data word length. Within each 32-bit field, the stored data sample is right-justified, with the least significant bit of the word in bit 0. In the Receive FIFO, unused bits are packed as zeroes above the most significant bit. In the Transmit FIFO, unused don’t-care bits are above the most significant bit (i.e., DMA and CPU access do not have to write to the unused bit locations). Logic in the Enhanced SSP automatically formats data in the Transmit FIFO so that the sample is properly transmitted on I2Sx_DATAOUT in the selected frame format.

Two separate and independent FIFOs are present for Transmit (to peripheral) and Receive (from peripheral) serial data. FIFOs are filled or emptied by programmed I/O or DMA bursts.

21.7.1.1 Programmed IO Considerations

FIFO filling and emptying can be performed by the processor in response to an Interrupt from the FIFO logic. Each FIFO has a programmable FIFO trigger threshold at which an Interrupt is triggered. When the number of entries in the Receive FIFO exceeds the SSCR1.RFT value, an interrupt is generated (if enabled), which signals the CPU to empty the Receive FIFO. When the number of entries in the Transmit FIFO is less than or equal to the SSCR1.TFT value plus 1, an Interrupt is generated (if enabled), which signals the CPU to refill the Transmit FIFO.

Users can also poll the Enhanced SSP Status register to determine how many samples are in a FIFO, and whether the FIFO is full or empty. Software is responsible for ensuring that the proper RFT and TFT values are chosen to prevent ROR and TUR error conditions.

Note: If the software attempts to read from an empty Receive FIFO, it will receive a duplicate of the previously read value.

21.7.1.2 DMA Considerations

The DMA controller can also be programmed to transfer data to and from the Enhanced SSP FIFOs. To prevent over-runs of the Transmit FIFO or under-runs of the Receive FIFO when using the DMA, be careful when setting the Transmit and Receive FIFO trigger threshold levels.

There are restrictions on how the DMA can be programmed when used with the SSP Controller.

- The DMA Transfer Width must be greater than or equal to the SSP data size. For example if the SSP Data Size is 16b then the DMA Transfer Width should be 16b.
- The DMA may not support the DMA Transfer Width of the SSP Data Size and therefore the DMA Transfer Width must be larger than the SSP Data Size. If this is the case then software must manage any extra data bits.
- The DMA Burst Transaction Length for RX must be less than or equal to the RX Threshold.
- The DMA Burst Transaction Length for TX must be less than or equal to the number of empty locations in the TX FIFO. A safe value is the Total TX FIFO Size - TX Threshold.
- DMA must be in Fixed Address mode to read or write the SSP Data Register.

In full-duplex formats where the Enhanced SSP always receives the same number of data samples as it transmits, the DMA should be set up to transmit and receive the same number of bytes.

Note: A TFT value of 0 means that there is one sample left in the TX FIFO.

Because the Enhanced SSP is not flow controlled, software must program the TX FIFO Threshold (TFT), RX FIFO Threshold (RFT), and the DMA burst size to ensure that a TX FIFO overflow or RX FIFO underflow does not occur. Software must also ensure that the Enhanced SSP DMA requests are properly prioritized in the system to prevent fatal overruns and under-runs.

The programming model for using the DMA is as follows:

- Program the total number of Transmit/Receive byte lengths, DMA burst, and DMA Width in the DMA.
- Set the preferred values in the Enhanced SSP Control registers.
- Enable the Enhanced SSP by setting SSCR0.SSE.
- Set the run bit in DMA Command Register.

- The DMA will wait for either the Transmit or Receive Service requests.
- If the Transmit/Receive byte length is not an even multiple of the transfer burst size, a trailing byte condition may occur.

21.7.2 Trailing Bytes in the Receive FIFO

When the number of samples in the Receive FIFO is less than its FIFO trigger threshold level, and no additional data is received, the remaining bytes are called trailing bytes. Trailing bytes can be handled by either the DMA or the processor, as indicated by the SSCR1.TRAIL bit. Trailing bytes are identified by means of a timeout mechanism and the existence of data within the Receive FIFO.

21.7.2.1 Timeout

A timeout condition exists when the Receive FIFO has been idle for a period of time (in APB clocks) defined by the value programmed within the Timeout register (SSTO). When a timeout occurs, the receiver timeout interrupt SSSR.TINT bit will be set to a 1, and if the Timeout Interrupt is enabled SSCR1.TINTE=1, a Timeout Interrupt will occur to signal the processor that a timeout condition has occurred. The timeout timer is reset after a new sample is received. Once the SSSR.TINT bit is set it must be cleared by software by writing a 1 to it. Clearing this bit also causes the Timeout Interrupt, if enabled, to be de-asserted.

21.7.2.2 Peripheral Trailing Byte Interrupt

It is possible for the DMA to reach the end of its Descriptor chain while removing Receive FIFO data. When this happens, the processor is forced to take over because the DMA can no longer service the Enhanced SSP request until a new chain is linked. When the DMA has reached the end of its Descriptor chain, and there is data in the receive FIFO, the Enhanced SSP will do the following:

- Sets the peripheral trailing byte interrupt SSSR.PINT bit to 1
- Asserts the Enhanced SSP Interrupt to signal to the processor that a Peripheral Trailing Byte Interrupt condition has occurred (if SSCR1.PINTE=1 to enable the interrupt).
- Sets the SSSR.EOC status bit which must be cleared by software. If more data is received after the EOC bit was set (and EOC bit is still set), then the SSSR.PINT bit will be set to a 1.

Once the SSSR.PINT bit is set, it must be cleared by software by writing a 1 to it. Clearing the SSSR.PINT bit also de-asserts the Peripheral Interrupt if it has been enabled (SSCR1.PINTE=1).

The remaining bytes must then be removed by means of a processor I/O as described in the processor-based method below, or by reprogramming a new Descriptor chain and restarting the DMA. Programmers need to be aware of this possibility. Refer to the DMA chapter for details on Descriptor programming and “end of chain” events.

21.7.2.3 Removing Trailing Bytes (Processor Based SSCR1.TRAIL=0)

This is the default method indicated by a zero in the SSCR1.TRAIL bit. In this case, no Receive DMA service request is generated. To read out the trailing bytes, software should wait for the timeout Interrupt and then read all remaining entries as indicated by the SSSR.RFL and SSSR.RNE bits within the Enhanced SSP Status register (SSSR).

Note: To use the Trailing bytes feature through the CPU, the Timeout Interrupt must be enabled by setting SSCR1.TINTE=1 (to enable the interrupt).

21.7.2.4 Removing Trailing Bytes (DMA Based SSCR1.TRAIL=1)

When the DMA is to handle trailing bytes (SSCR1.TRAIL = 1) a DMA service request is automatically issued for the remaining number of samples left in the Receive buffer. The DMA will then empty the contents of the Receive buffer unless the DMA reaches the end of its Descriptor chain. If a timeout occurs, the processor is only interrupted by means of a Timeout Interrupt if it has been enabled by setting SSCR1.TINTE=1. When handling trailing bytes by means of the DMA, if a timeout occurs and the receive FIFO is empty, an End-of-Receive (EOR) will be sent to the DMA Controller. If an EOC occurs at the time that the last sample is read out of the FIFO (the DMA descriptor chain was just exactly long enough), and the timeout counter is still running (that is, a time out has not occurred and the SSTO register is non-zero), then, when the time out does occur, the Enhanced SSP will generate a DMA request which will create an RAS interrupt from the DMA. When this occurs, software must re-program the DMA registers and re-enable the channel for the Enhanced SSP to send its EOR to the DMA controller.

21.11.8 reg_IPCX_type (IPCX)—Offset 38h

The Inter-process Status and Message register for IA-32 contains a message sent from the IA-32 CPU to LPE. The format of the CPU message bits (61:0) is not defined in the HW specs. It is defined in the LPE Firmware specifications. The message may contain optional data fields stored in the shared memory region (mailbox). When the message is written in this register, the software must set bit 63 to indicate that the IPCIA is not empty. Setting Busy also asserts interrupt request to LPE if the interrupt is enabled in the IMRLPEIA. After LPE reads the message code from the register, it must perform a write with bit 63 cleared. The IA-32 CPU must not attempt to write into IPCIA if bit 63 is set.

21.11.23 reg_IPCPSH_type (IPCPSH)—Offset B0h

The Inter-process Status and Message register for PSH contains a message sent from the PSH CPU to LPE. The format of the CPU message bits (29:0) is not defined in the HW specs. It is defined in the LPE Firmware specifications. The message may contain optional data fields stored in the shared memory region (mailbox). When the message is written in this register, the software must set bit 63 to indicate that the IPCPSH is not empty. Setting Busy also asserts interrupt request to LPE if the interrupt is enabled in the IMRLPEPSH. After LPE reads the message code from the register, it must perform a write with bit 63 cleared. The PSH CPU must not attempt to write into IPCIA if bit 63 is set.

21.11.24 reg_IPCLPEPSH_type (IPCLPEPSH)—Offset B8h

Inter-process Status and Message register for LPE contains a message sent from LPE to PSH. The format of the CPU message bits 29:0 is defined in the LPE Firmware specifications. The message may contain optional data fields stored in the shared memory region (mailbox). When software writes the message is in this register, it should set bit 63 to indicate that the new data is written. When PSH reads the message code from the register, and writes back with the bit 63 cleared. When the PSH CPU processes the message sent by LPE, it may set bit 62 in IPCLPEPSH to assert interrupt request to LPE. The LPE must not attempt to write into IPCD if bit 63 is set.

21.12.3 SSP Status Register (SSSR)—Offset 8h

The Enhanced SSP Status registers contain bits that signal overrun errors as well as the Transmit and Receive FIFO service requests. Each of these hardware-detected events signals an Interrupt request to the Interrupt controller. The Status register also contains flags that indicate when the Enhanced SSP is actively transmitting data, when the Transmit FIFO is not full, and when the Receive FIFO is not empty. One Interrupt signal is sent to the Interrupt Controller for each SSP. These events can cause an Interrupt: End-of-Chain, Receiver Time-out, Peripheral Trailing Byte, Receive FIFO overrun, Receive FIFO request, and Transmit FIFO request.

21.12.4 SSP Interupt Test Register (SSITR)—Offset Ch

The read-write SSP Interrupt Test registers should be used only for testing purposes. Writing a 1 to the test transmit FIFO request SSITR.TTFS, bit 5, will generate a non-maskable Interrupt strobe signal to the Interrupt controller, and a DMA request for the Transmit FIFO. Writing a 1 to the test receive FIFO request SSITR.TRFS, bit 6, will generate a non-maskable Interrupt strobe signal to the Interrupt controller, and a DMA request for the Receive FIFO. Writing a 1 to the test receive FIFO overrun bit SSITR.TROR, bit 7, will generate a non-maskable Interrupt strobe signal to the Interrupt controller only, no DMA request will be made. Setting any of these bits will also cause the corresponding status bit(s) to be set in the Enhanced SSP Status register (SSSR). The Interrupt and/or service request, caused by the setting of one of these test bits, will remain active until the test bit is cleared by writing a 0 it. Note that Writes to reserved bits must be zeroes, and Read value of these bits are undetermined.

21.12.5 SSP Data Register (SSDR)—Offset 10h

The Enhanced SSP Data registers are single address locations that Read-Write data transfers can access. The SSDR represents two physical registers: the first is temporary storage for data on its way out through the Transmit FIFO, the other is temporary storage for data coming in through the Receive FIFO. As the system accesses the

register, FIFO Control logic transfers data automatically between register and FIFO as fast as the system moves it. Data in the FIFO shifts up or down to accommodate the new word (unless it's an attempted Write to a full Transmit FIFO). Status bits (such as SSSR.TFL, SSSR.RFL, SSSR.RNE, and SSSR.TNF) show users whether the FIFO is full, above/below a programmable FIFO trigger threshold, or empty. For Transmit data transfers (Write from system to SSP peripheral), the register can be loaded (written) by the system processor anytime it falls below its threshold level when using programmed I/O. When a data size of less than 32-bits is selected, users should not left-justify data written to the Transmit FIFO. Transmit logic left-justifies the data and ignores any unused bits. Received data of less than 32-bits is automatically right-justified in the Receive FIFO. When the Enhanced SSP is programmed for National Semiconductor Microwire* frame format and if the size for Transmit data is 8-bits as selected by SSCR1.MWDS=0, then the most significant 24-bits are ignored. Similarly, if the size for the Transmit data is 16-bit as selected by SSCR1.MWDS=1, then most significant 16-bits are ignored. The SSCR0.DSS field controls the Receive data size.

21.12.11 SSP Audio Clock Divider (SSACD)—Offset 3Ch

The Enhanced SSP Audio Clock Divider registers are read-write registers that indicate which clock frequency is sent to the Enhanced SSP and to the SYSCLK pin. If SSCR0.SCR is not 0, then there is no guaranteed phase relationship between SYSCLK and SSPSCLK. The SSPSFRM Frame Synch Sampling Frequency is calculated by dividing the chosen PLL output clock frequency (SSACD.ACPS) by the chosen divider (SSACD.ACDS) which gives the SYSCLK frequency. The SYSCLK is then divided by 4 (or by 1) to get the SSPSCLK. The SSPSCLK is divided by the data size (EDSS, DSS values) and by the number of time slots being used (SSCR0.FRDC value), if any, to give the

SSPSFRM frequency. Note that Writes to reserved bits must be zeroes, and Read value of these bits are undetermined. It's important to note that this feature is only available if implemented by the project instantiation. A clock source and mux must be instantiated outside of the SSP controller for this feature to work. Only this register is designed into the SSP Controller.

Bit Range	Default & Access	Description
31:12	0b RO	**RSVD0:** Reserved
11	0b RW	**ASRC Interrupt Mask (ASRC_INTR_MASK):** Setting this bit to 1 masks the ASRC interrupt that is generated every time the frame count matches the frame threshold. Software should override this bit, since it have no reset value
10	0b RW	**ASRC frame count enable (ASRC_FRM_CNTR_EN):** Setting this bit enables the frame counter to start running. Clearing this bit will make the frame counter go back to zero immediately.
9	0b RW/AC	**ASRC Counter Clear (ASRC_CNTR_CLR):** Setting this to 1 will clear the ASRC Free running counter. This bit will self clear after the counter is cleared.
8	0b RW	**ASRC Counter enable (ASRC_CNTR_EN):** Setting this bit makes the Free running ASRC counter to start running. Clearing this bit will make it pause and hold it's current value.
7	1b RW	**Fifo empty fix enable (FIFO_EMPTY_FIX_EN):** Corner cases between the FIFO empty and APB writes happening to the TX FIFO around the time the new data needs to be sent out on the TXD are fixed with this bit.
6	1b RW	**Underrun fix enable (UNDRN_FIX_EN):** OSC to PLL switch along with underrun was causing unexpected behavior. This bit enables the fix for that bug.
5:4	00b RW	**Reserved:** This is a RW bit with no effect on IP behavior
3	0b RW	**Clock Delay Enable (CLK_DEL_EN):** When CLK_DEL_EN = 0, delay logic for capturing data from device is disabled. When CLK_DEL_EN = 1, delay logic for capturing data from device is delayed by half a period of the IO clock
2	0b RW	**Slave Mode External Clock Run Enable (SLV_EXT_CLK_RUN_EN):** When in Slave mode the receive state machine requires several clock edges (around 6) to properly sample incoming data. This bit enables a free running clock to the receive state machine before any data is received to properly sample the incoming data. 0 = Disable 1 = Enable
1	0b RW	**Mode 1 Underrun Fix (Underrun_fix_1):** Mode 1 of transmit underrun fix. In this mode, new data will start on the underrun slot. This function is only appled to TI and PSP modes. 0 = disable mode 1 1 = enable mode 1 If both underrun modes are enable, mode 1 has higher priority.
0	0b RW	**Mode 0 Underrun Fix (Underrun_fix_0):** Mode 0 of transmit underrun fix. In this mode, new data will always start at slot 0. This function is only applied to TI and PSP modes. 0 = disable mode 1 1 = enable mode 1

21.12.13 SSP Frame Select Register (SSFS)—Offset 44h

The SSP Frame select register is used to choose which frame signal to assert when accessing a slave device. SW drivers should set this register to assert the correct frame select to the targetted device.

21.12.14 SSP Slot Frame Counter Register[0-7] (FRAME_CNT[0-7])—Offset 48h, Count 8, Stride 4h

The slot frame counter is typically used in Audio modes and increments the counter every two SSPSCLKs. This allows the OS to check the progress of a transfer. Since the SSP can support upto 8 slots in network mode there are 8 slot frame counters.

21.12.15 SSP FIFO Level Register (SFIFOL)—Offset 68h

The SFIFOL register describes the current state of the RX and TX FIFOs. Not all bits of the TFL and RFL fields are used and depends on the actual hardware FIFO depth used in the instantiation of the SSP controller. This FIFO level register is meant to replace the SSSR.TFL and SSR.RFL fields.

21.12.16 SSP FIFO Trigger Threshold Register (SFIFOTT)—Offset 6Ch

The SFIFOTT is a register that determines when the the FIFOs will assert an interrupt for FIFO full indication. This is meant to replace the SSCR1.RFT and SSCR1.TFT legacy registers. The max size of these registers is based on the actualy FIFO depth in hardware and not the actual size of the bit field.

Bit Range	Default & Access	Description
31:16	0000h RW	**Receive FIFO Trigger Threshold (RFT):** Sets threshold level at which receive FIFO asserts interrupt. This level should be set to the desired threshold value minus 1. Notes on setting the RFT value. This applies to cases where SSP is receiving data from a device and is interfaced with a DMA channel via the hardware handshake mechanism. Please follow the following recommendations: 1. Number of bits denoted by the (DSS, EDSS) parameters in the SSP should match the SRC_TR_WIDTH programmed in the DMA channel. 2. (RFT+1) should be equal to (SRC_MSIZE). 3. Another option to 2 is to keep the BLOCK_TS in the DMA to be a multiple of (RFT+1)
15:0	0000h RW	**Transmit FIFO Trigger Threshold (TFT):** Sets threshold level at which transmit FIFO asserts interrupt. This level should be set to the desired threshold value minus 1.

21.12.17 SSP Control 3 Register (SSCR3)—Offset 70h

31:18	0b RO	**RSVD0:** Reserved
17	1b RW	**Sync Fix Enable (SYN_FIX_EN):** This is a chicken bit for enabling the synchronizer fix for clr_underrun_ssp signal. SW should preserve this bit at its default value.
16	0b RW	**Master Mode Clock Enable (MST_CLK_EN):** When in single slot master mode (which is the mode used for emulating I2S or LJ master mode), the SSP core can stop the clock on a Tx underflow condition, preventing the Rx side from receiving data. This bit, when set, forces the clock to run when a Tx underflow happens, thereby allowing Rx side to continue functioning while Tx side is in underflow. SW should set this bit when I2S or LJ master mode is enabled i.e. bits 0 and 1 in this register are both set or when using 1-slot PCM (SFS or LFS) master mode operation. Otherwise, SW should leave this at 0.
15	1b RW	**Stretch RX Pulse (STRETCH_RX):** HW uses this as a chicken bit to stretch the RX pulse for proper clock crossing between SSP and APB domains. Note this bit is not tied to any specific SSP/PCM/I2S modes. SW should preserve this bit as the default value.
14	1b RW	**Stretch TX Pulse (STRETCH_TX):** HW uses this as a chicken bit to stretch the TX pulse for proper clock crossing between SSP and APB domains. Note this bit is not tied to any specific SSP/PCM/I2S modes. SW should preserve this bit as the default value.

21.13.3 SSP Status Register (SSSR)—Offset 8h

The Enhanced SSP Status registers contain bits that signal overrun errors as well as the Transmit and Receive FIFO service requests. Each of these hardware-detected events signals an Interrupt request to the Interrupt controller. The Status register also contains flags that indicate when the Enhanced SSP is actively transmitting data, when the Transmit FIFO is not full, and when the Receive FIFO is not empty. One Interrupt signal is sent to the Interrupt Controller for each SSP. These events can cause an Interrupt: End-of-Chain, Receiver Time-out, Peripheral Trailing Byte, Receive FIFO overrun, Receive FIFO request, and Transmit FIFO request.

21.13.4 SSP Interupt Test Register (SSITR)—Offset Ch

The read-write SSP Interrupt Test registers should be used only for testing purposes. Writing a 1 to the test transmit FIFO request SSITR.TTFS, bit 5, will generate a non-maskable Interrupt strobe signal to the Interrupt controller, and a DMA request for the Transmit FIFO. Writing a 1 to the test receive FIFO request SSITR.TRFS, bit 6, will generate a non-maskable Interrupt strobe signal to the Interrupt controller, and a DMA request for the Receive FIFO. Writing a 1 to the test receive FIFO overrun bit SSITR.TROR, bit 7, will generate a non-maskable Interrupt strobe signal to the Interrupt controller only, no DMA request will be made. Setting any of these bits will also cause the corresponding status bit(s) to be set in the Enhanced SSP Status register (SSSR). The Interrupt and/or service request, caused by the setting of one of these test bits, will remain active until the test bit is cleared by writing a 0 it. Note that Writes to reserved bits must be zeroes, and Read value of these bits are undetermined.

21.13.5 SSP Data Register (SSDR)—Offset 10h

The Enhanced SSP Data registers are single address locations that Read-Write data transfers can access. The SSDR represents two physical registers: the first is temporary storage for data on its way out through the Transmit FIFO, the other is temporary storage for data coming in through the Receive FIFO. As the system accesses the

register, FIFO Control logic transfers data automatically between register and FIFO as fast as the system moves it. Data in the FIFO shifts up or down to accommodate the new word (unless it's an attempted Write to a full Transmit FIFO). Status bits (such as SSSR.TFL, SSSR.RFL, SSSR.RNE, and SSSR.TNF) show users whether the FIFO is full, above/below a programmable FIFO trigger threshold, or empty. For Transmit data transfers (Write from system to SSP peripheral), the register can be loaded (written) by the system processor anytime it falls below its threshold level when using programmed I/O. When a data size of less than 32-bits is selected, users should not left-justify data written to the Transmit FIFO. Transmit logic left-justifies the data and ignores any unused bits. Received data of less than 32-bits is automatically right-justified in the Receive FIFO. When the Enhanced SSP is programmed for National Semiconductor Microwire* frame format and if the size for Transmit data is 8-bits as selected by SSCR1.MWDS=0, then the most significant 24-bits are ignored. Similarly, if the size for the Transmit data is 16-bit as selected by SSCR1.MWDS=1, then most significant 16-bits are ignored. The SSCR0.DSS field controls the Receive data size.

21.13.11 SSP Audio Clock Divider (SSACD)—Offset 3Ch

The Enhanced SSP Audio Clock Divider registers are read-write registers that indicate which clock frequency is sent to the Enhanced SSP and to the SYSCLK pin. If SSCR0.SCR is not 0, then there is no guaranteed phase relationship between SYSCLK and SSPSCLK. The SSPSFRM Frame Synch Sampling Frequency is calculated by dividing the chosen PLL output clock frequency (SSACD.ACPS) by the chosen divider (SSACD.ACDS) which gives the SYSCLK frequency. The SYSCLK is then divided by 4 (or by 1) to get the SSPSCLK. The SSPSCLK is divided by the data size (EDSS, DSS values) and by the number of time slots being used (SSCR0.FRDC value), if any, to give the

SSPSFRM frequency. Note that Writes to reserved bits must be zeroes, and Read value of these bits are undetermined. It's important to note that this feature is only available if implemented by the project instantiation. A clock source and mux must be instantiated outside of the SSP controller for this feature to work. Only this register is designed into the SSP Controller.

3	0b RW	**Clock Delay Enable (CLK_DEL_EN):** When CLK_DEL_EN = 0, delay logic for capturing data from device is disabled. When CLK_DEL_EN = 1, delay logic for capturing data from device is delayed by half a period of the IO clock
2	0b RW	**Slave Mode External Clock Run Enable (SLV_EXT_CLK_RUN_EN):** When in Slave mode the receive state machine requires several clock edges (around 6) to properly sample incoming data. This bit enables a free running clock to the receive state machine before any data is received to properly sample the incoming data. 0 = Disable 1 = Enable
1	0b RW	**Mode 1 Underrun Fix (Underrun_fix_1):** Mode 1 of transmit underrun fix. In this mode, new data will start on the underrun slot. This function is only appled to TI and PSP modes. 0 = disable mode 1 1 = enable mode 1 If both underrun modes are enable, mode 1 has higher priority.
0	0b RW	**Mode 0 Underrun Fix (Underrun_fix_0):** Mode 0 of transmit underrun fix. In this mode, new data will always start at slot 0. This function is only applied to TI and PSP modes. 0 = disable mode 1 1 = enable mode 1

21.13.13 SSP Frame Select Register (SSFS)—Offset 44h

The SSP Frame select register is used to choose which frame signal to assert when accessing a slave device. SW drivers should set this register to assert the correct frame select to the targetted device.

21.13.14 SSP Slot Frame Counter Register[0-7] (FRAME_CNT[0-7])—Offset 48h, Count 8, Stride 4h

The slot frame counter is typically used in Audio modes and increments the counter every two SSPSCLKs. This allows the OS to check the progress of a transfer. Since the SSP can support upto 8 slots in network mode there are 8 slot frame counters.

21.13.15 SSP FIFO Level Register (SFIFOL)—Offset 68h

The SFIFOL register describes the current state of the RX and TX FIFOs. Not all bits of the TFL and RFL fields are used and depends on the actual hardware FIFO depth used in the instantiation of the SSP controller. This FIFO level register is meant to replace the SSSR.TFL and SSR.RFL fields.

21.13.16 SSP FIFO Trigger Threshold Register (SFIFOTT)—Offset 6Ch

The SFIFOTT is a register that determines when the the FIFOs will assert an interrupt for FIFO full indication. This is meant to replace the SSCR1.RFT and SSCR1.TFT legacy registers. The max size of these registers is based on the actualy FIFO depth in hardware and not the actual size of the bit field.

Bit Range	Default & Access	Description
31:16	0000h RW	**Receive FIFO Trigger Threshold (RFT):** Sets threshold level at which receive FIFO asserts interrupt. This level should be set to the desired threshold value minus 1. Notes on setting the RFT value. This applies to cases where SSP is receiving data from a device and is interfaced with a DMA channel via the hardware handshake mechanism. Please follow the following recommendations: 1. Number of bits denoted by the (DSS, EDSS) parameters in the SSP should match the SRC_TR_WIDTH programmed in the DMA channel. 2. (RFT+1) should be equal to (SRC_MSIZE). 3. Another option to 2 is to keep the BLOCK_TS in the DMA to be a multiple of (RFT+1)
15:0	0000h RW	**Transmit FIFO Trigger Threshold (TFT):** Sets threshold level at which transmit FIFO asserts interrupt. This level should be set to the desired threshold value minus 1.

21.13.17 SSP Control 3 Register (SSCR3)—Offset 70h

31:18	0b RO	**RSVD0:** Reserved
17	1b RW	**Sync Fix Enable (SYN_FIX_EN):** This is a chicken bit for enabling the synchronizer fix for clr_underrun_ssp signal. SW should preserve this bit at its default value.
16	0b RW	**Master Mode Clock Enable (MST_CLK_EN):** When in single slot master mode (which is the mode used for emulating I2S or LJ master mode), the SSP core can stop the clock on a Tx underflow condition, preventing the Rx side from receiving data. This bit, when set, forces the clock to run when a Tx underflow happens, thereby allowing Rx side to continue functioning while Tx side is in underflow. SW should set this bit when I2S or LJ master mode is enabled i.e. bits 0 and 1 in this register are both set or when using 1-slot PCM (SFS or LFS) master mode operation. Otherwise, SW should leave this at 0.
15	1b RW	**Stretch RX Pulse (STRETCH_RX):** HW uses this as a chicken bit to stretch the RX pulse for proper clock crossing between SSP and APB domains. Note this bit is not tied to any specific SSP/PCM/I2S modes. SW should preserve this bit as the default value.
14	1b RW	**Stretch TX Pulse (STRETCH_TX):** HW uses this as a chicken bit to stretch the TX pulse for proper clock crossing between SSP and APB domains. Note this bit is not tied to any specific SSP/PCM/I2S modes. SW should preserve this bit as the default value.

21.14.3 SSP Status Register (SSSR)—Offset 8h

The Enhanced SSP Status registers contain bits that signal overrun errors as well as the Transmit and Receive FIFO service requests. Each of these hardware-detected events signals an Interrupt request to the Interrupt controller. The Status register also contains flags that indicate when the Enhanced SSP is actively transmitting data, when the Transmit FIFO is not full, and when the Receive FIFO is not empty. One Interrupt signal is sent to the Interrupt Controller for each SSP. These events can cause an Interrupt: End-of-Chain, Receiver Time-out, Peripheral Trailing Byte, Receive FIFO overrun, Receive FIFO request, and Transmit FIFO request.

21.14.4 SSP Interupt Test Register (SSITR)—Offset Ch

The read-write SSP Interrupt Test registers should be used only for testing purposes. Writing a 1 to the test transmit FIFO request SSITR.TTFS, bit 5, will generate a non-maskable Interrupt strobe signal to the Interrupt controller, and a DMA request for the Transmit FIFO. Writing a 1 to the test receive FIFO request SSITR.TRFS, bit 6, will generate a non-maskable Interrupt strobe signal to the Interrupt controller, and a DMA request for the Receive FIFO. Writing a 1 to the test receive FIFO overrun bit SSITR.TROR, bit 7, will generate a non-maskable Interrupt strobe signal to the Interrupt controller only, no DMA request will be made. Setting any of these bits will also cause the corresponding status bit(s) to be set in the Enhanced SSP Status register (SSSR). The Interrupt and/or service request, caused by the setting of one of these test bits, will remain active until the test bit is cleared by writing a 0 it. Note that Writes to reserved bits must be zeroes, and Read value of these bits are undetermined.

21.14.5 SSP Data Register (SSDR)—Offset 10h

The Enhanced SSP Data registers are single address locations that Read-Write data transfers can access. The SSDR represents two physical registers: the first is temporary storage for data on its way out through the Transmit FIFO, the other is temporary storage for data coming in through the Receive FIFO. As the system accesses the

register, FIFO Control logic transfers data automatically between register and FIFO as fast as the system moves it. Data in the FIFO shifts up or down to accommodate the new word (unless it's an attempted Write to a full Transmit FIFO). Status bits (such as SSSR.TFL, SSSR.RFL, SSSR.RNE, and SSSR.TNF) show users whether the FIFO is full, above/below a programmable FIFO trigger threshold, or empty. For Transmit data transfers (Write from system to SSP peripheral), the register can be loaded (written) by the system processor anytime it falls below its threshold level when using programmed I/O. When a data size of less than 32-bits is selected, users should not left-justify data written to the Transmit FIFO. Transmit logic left-justifies the data and ignores any unused bits. Received data of less than 32-bits is automatically right-justified in the Receive FIFO. When the Enhanced SSP is programmed for National Semiconductor Microwire* frame format and if the size for Transmit data is 8-bits as selected by SSCR1.MWDS=0, then the most significant 24-bits are ignored. Similarly, if the size for the Transmit data is 16-bit as selected by SSCR1.MWDS=1, then most significant 16-bits are ignored. The SSCR0.DSS field controls the Receive data size.

21.14.11 SSP Audio Clock Divider (SSACD)—Offset 3Ch

The Enhanced SSP Audio Clock Divider registers are read-write registers that indicate which clock frequency is sent to the Enhanced SSP and to the SYSCLK pin. If SSCR0.SCR is not 0, then there is no guaranteed phase relationship between SYSCLK and SSPSCLK. The SSPSFRM Frame Synch Sampling Frequency is calculated by dividing the chosen PLL output clock frequency (SSACD.ACPS) by the chosen divider (SSACD.ACDS) which gives the SYSCLK frequency. The SYSCLK is then divided by 4 (or by 1) to get the SSPSCLK. The SSPSCLK is divided by the data size (EDSS, DSS values) and by the number of time slots being used (SSCR0.FRDC value), if any, to give the

SSPSFRM frequency. Note that Writes to reserved bits must be zeroes, and Read value of these bits are undetermined. It's important to note that this feature is only available if implemented by the project instantiation. A clock source and mux must be instantiated outside of the SSP controller for this feature to work. Only this register is designed into the SSP Controller.

21.14.14 SSP Slot Frame Counter Register[0-7] (FRAME_CNT[0-7])—Offset 48h, Count 8, Stride 4h

The slot frame counter is typically used in Audio modes and increments the counter every two SSPSCLKs. This allows the OS to check the progress of a transfer. Since the SSP can support upto 8 slots in network mode there are 8 slot frame counters.

21.14.15 SSP FIFO Level Register (SFIFOL)—Offset 68h

The SFIFOL register describes the current state of the RX and TX FIFOs. Not all bits of the TFL and RFL fields are used and depends on the actual hardware FIFO depth used in the instantiation of the SSP controller. This FIFO level register is meant to replace the SSSR.TFL and SSR.RFL fields.

21.14.16 SSP FIFO Trigger Threshold Register (SFIFOTT)—Offset 6Ch

The SFIFOTT is a register that determines when the the FIFOs will assert an interrupt for FIFO full indication. This is meant to replace the SSCR1.RFT and SSCR1.TFT legacy registers. The max size of these registers is based on the actualy FIFO depth in hardware and not the actual size of the bit field.

Bit Range	Default & Access	Description
31:16	0000h RW	**Receive FIFO Trigger Threshold (RFT):** Sets threshold level at which receive FIFO asserts interrupt. This level should be set to the desired threshold value minus 1. Notes on setting the RFT value. This applies to cases where SSP is receiving data from a device and is interfaced with a DMA channel via the hardware handshake mechanism. Please follow the following recommendations: 1. Number of bits denoted by the (DSS, EDSS) parameters in the SSP should match the SRC_TR_WIDTH programmed in the DMA channel. 2. (RFT+1) should be equal to (SRC_MSIZE). 3. Another option to 2 is to keep the BLOCK_TS in the DMA to be a multiple of (RFT+1)
15:0	0000h RW	**Transmit FIFO Trigger Threshold (TFT):** Sets threshold level at which transmit FIFO asserts interrupt. This level should be set to the desired threshold value minus 1.

21.14.17 SSP Control 3 Register (SSCR3)—Offset 70h

17	1b RW	**Sync Fix Enable (SYN_FIX_EN):** This is a chicken bit for enabling the synchronizer fix for clr_underrun_ssp signal. SW should preserve this bit at its default value.
16	0b RW	**Master Mode Clock Enable (MST_CLK_EN):** When in single slot master mode (which is the mode used for emulating I2S or LJ master mode), the SSP core can stop the clock on a Tx underflow condition, preventing the Rx side from receiving data. This bit, when set, forces the clock to run when a Tx underflow happens, thereby allowing Rx side to continue functioning while Tx side is in underflow. SW should set this bit when I2S or LJ master mode is enabled i.e. bits 0 and 1 in this register are both set or when using 1-slot PCM (SFS or LFS) master mode operation. Otherwise, SW should leave this at 0.
15	1b RW	**Stretch RX Pulse (STRETCH_RX):** HW uses this as a chicken bit to stretch the RX pulse for proper clock crossing between SSP and APB domains. Note this bit is not tied to any specific SSP/PCM/I2S modes. SW should preserve this bit as the default value.

21.15.1 reg_SAR_type (SAR0)—Offset 0h

The starting source address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the source address of the current transfer.

SAR																															

Bit Range	Default & Access	Description
31:0	0h RW	**SAR:** Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

21.15.2 reg_DAR_type (DAR0)—Offset 8h

The starting destination address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the destination address of the current transfer.

31:0	0h RW	**DAR:** Current Destination Address of DMA transfer. Updated after each destination transfer. The DINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every destination transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated destination transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Write Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Write address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA write was a burst write (i.e. burst length) 1), the read-back value reflects the first address of the burst write since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA write progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

21.15.3 reg_LLP_type (LLP0)—Offset 10h

Note: You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled The LLP register has two functions: The logical result of the equation LLP.LOC != 0 is used to set up the type of DMA transfer-single or multi-block. Table shows how the method of updating the channel registers is a function of LLP.LOC != 0. If LLP.LOC is set to 0x0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type. LLP.LOC != 0 contains the pointer to the next LLI for block chaining using linked lists, The LLPx register can also point to the address where write-back of the control and source/destination status information occur after block completion.

21.15.5 reg_CTL_HI_type (CTL_HI0)—Offset 1Ch

This register contains fields that control the DMA transfer. The CTL_HI register is part of the block descriptor (linked list item - LLI) when block chaining is enabled. It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled.If status write-back is enabled, CTL_HI is written to then control registers location of the LLI in system memory at the end of the block transfer.

CH_CLASS | CH_WEIGHT | DONE | BLOCK_TS

Bit Range	Default & Access	Description
31:29	0h RW	**CH_CLASS:** Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below

Bit Range	Default & Access	Description
28:18	0h RW	**CH_WEIGHT:** Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to (2^11-1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	**DONE:** If status write-back is enabled, the upper word of the control register, CTL_HIn, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	**BLOCK_TS:** Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesnt mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to (2^17 -1) = (128 KB - 1).

21.15.6 reg_SSTAT_type (SSTAT0)—Offset 20h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. SAR																															

Bit Range	Default & Access	Description
31:0	0h RW	**SAR:** Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

DAR																															

Bit Range	Default & Access	Description
31:0	0h RW	**DAR:** Current Destination Address of DMA transfer. Updated after each destination transfer. The DINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every destination transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated destination transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Write Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Write address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA write was a burst write (i.e. burst length) 1), the read-back value reflects the first address of the burst write since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA write progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

21.15.16 reg_LLP_type (LLP1)—Offset 68h

Note: You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled The LLP register has two functions: The logical result of the equation LLP.LOC != 0 is used to set up the type of DMA transfer-single or multi-block. Table shows how the method of updating the channel registers is a function of LLP.LOC != 0. If LLP.LOC is set to 0x0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type. LLP.LOC != 0 contains the pointer to the next LLI for block chaining using linked lists, The LLPx register can also point to the address where write-back of the control and source/destination status information occur after block completion.

CH_CLASS | CH_WEIGHT | DONE | BLOCK_TS

Bit Range	Default & Access	Description
31:29	0h RW	**CH_CLASS:** Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below

Bit Range	Default & Access	Description
28:18	0h RW	**CH_WEIGHT:** Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to (2^11-1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	**DONE:** If status write-back is enabled, the upper word of the control register, CTL_HIn, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	**BLOCK_TS:** Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesnt mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to (2^17 -1) = (128 KB - 1).

21.15.19 reg_SSTAT_type (SSTAT1)—Offset 78h

The Source Gather register contains two fields: Source gather count field (SGRx.SGC). Specifies the number of contiguous source transfers of CTLx.SRC_TR_WIDTH between successive gather intervals. This is defined as a gather boundary. Source gather interval field (SGRx.SGI). Specifies the source address increment/decrement in multiples of CTLx.SRC_TR_WIDTH on a gather boundary when gather mode is enabled for the source transfer. The CTLx.SINC field controls whether the address increments or decrements. When the CTLx.SINC field indicates a fixed-address control, then the address remains constant throughout the transfer and the SGRx register is ignored.

Specifies the destination address increment/decrement in multiples of CTLx.DST_TR_WIDTH on a scatter boundary when scatter mode is enabled for the destination transfer. The CTLx.DINC field controls whether the address increments or decrements. When the CTLx.DINC field indicates a fixed address control, then the address remains constant throughout the transfer and the DSRx register is ignored.

Bit Range	Default & Access	Description
31:0	0h RW	**SAR:** Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

21.15.29 reg_LLP_type (LLP2)—Offset C0h

Note: You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled The LLP register has two functions: The logical result of the equation LLP.LOC != 0 is used to set up the type of DMA transfer-single or multi-block. Table shows how the method of updating the channel registers is a function of LLP.LOC != 0. If LLP.LOC is set to 0x0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type. LLP.LOC != 0 contains the pointer to the next LLI for block chaining using linked lists, The LLPx register can also point to the address where write-back of the control and source/destination status information occur after block completion.

CH_CLASS | CH_WEIGHT | DONE | BLOCK_TS

Bit Range	Default & Access	Description
31:29	0h RW	**CH_CLASS:** Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below

Bit Range	Default & Access	Description
28:18	0h RW	**CH_WEIGHT:** Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to (2^11-1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	**DONE:** If status write-back is enabled, the upper word of the control register, CTL_HIn, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	**BLOCK_TS:** Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesnt mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to (2^17 -1) = (128 KB - 1).

21.15.32 reg_SSTAT_type (SSTAT2)—Offset D0h

The Source Gather register contains two fields: Source gather count field (SGRx.SGC). Specifies the number of contiguous source transfers of CTLx.SRC_TR_WIDTH between successive gather intervals. This is defined as a gather boundary. Source gather interval field (SGRx.SGI). Specifies the source address increment/decrement in multiples of CTLx.SRC_TR_WIDTH on a gather boundary when gather mode is enabled for the source transfer. The CTLx.SINC field controls whether the address increments or decrements. When the CTLx.SINC field indicates a fixed-address control, then the address remains constant throughout the transfer and the SGRx register is ignored.

Bit Range	Default & Access	Description
31:0	0h RW	**SAR:** Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

21.15.42 reg_LLP_type (LLP3)—Offset 118h

Note: You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled The LLP register has two functions: The logical result of the equation LLP.LOC != 0 is used to set up the type of DMA transfer-single or multi-block. Table shows how the method of updating the channel registers is a function of LLP.LOC != 0. If LLP.LOC is set to 0x0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type. LLP.LOC != 0 contains the pointer to the next LLI for block chaining using linked lists, The LLPx register can also point to the address where write-back of the control and source/destination status information occur after block completion.

CH_CLASS	CH_WEIGHT	DONE	BLOCK_TS

Bit Range	Default & Access	Description
31:29	0h RW	**CH_CLASS:** Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below

Bit Range	Default & Access	Description
28:18	0h RW	**CH_WEIGHT:** Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to (2^11-1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	**DONE:** If status write-back is enabled, the upper word of the control register, CTL_HIn, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	**BLOCK_TS:** Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesnt mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to (2^17 -1) = (128 KB - 1).

21.15.51 reg_SGR_type (SGR3)—Offset 150h

The Source Gather register contains two fields: Source gather count field (SGRx.SGC). Specifies the number of contiguous source transfers of CTLx.SRC_TR_WIDTH between successive gather intervals. This is defined as a gather boundary. Source gather interval field (SGRx.SGI). Specifies the source address increment/decrement in multiples of CTLx.SRC_TR_WIDTH on a gather boundary when gather mode is enabled for the source transfer. The CTLx.SINC field controls whether the address increments or decrements. When the CTLx.SINC field indicates a fixed-address control, then the address remains constant throughout the transfer and the SGRx register is ignored.

SAR

Bit Range	Default & Access	Description
31:0	0h RW	**SAR:** Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

21.15.55 reg_LLP_type (LLP4)—Offset 170h

Note: You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled The LLP register has two functions: The logical result of the equation LLP.LOC != 0 is used to set up the type of DMA transfer-single or multi-block. Table shows how the method of updating the channel registers is a function of LLP.LOC != 0. If LLP.LOC is set to 0x0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type. LLP.LOC != 0 contains the pointer to the next LLI for block chaining using linked lists, The LLPx register can also point to the address where write-back of the control and source/destination status information occur after block completion.

Fields: CH_CLASS | CH_WEIGHT | DONE | BLOCK_TS

Bit Range	Default & Access	Description
31:29	0h RW	**CH_CLASS:** Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below

Bit Range	Default & Access	Description
28:18	0h RW	**CH_WEIGHT:** Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to (2^11-1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	**DONE:** If status write-back is enabled, the upper word of the control register, CTL_HIn, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	**BLOCK_TS:** Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesnt mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to (2^17 -1) = (128 KB - 1).

21.15.58 reg_SSTAT_type (SSTAT4)—Offset 180h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. 21.15.64 reg_SGR_type (SGR4)—Offset 1A8h

The Source Gather register contains two fields: Source gather count field (SGRx.SGC). Specifies the number of contiguous source transfers of CTLx.SRC_TR_WIDTH between successive gather intervals. This is defined as a gather boundary. Source gather interval field (SGRx.SGI). Specifies the source address increment/decrement in multiples of CTLx.SRC_TR_WIDTH on a gather boundary when gather mode is enabled for the source transfer. The CTLx.SINC field controls whether the address increments or decrements. When the CTLx.SINC field indicates a fixed-address control, then the address remains constant throughout the transfer and the SGRx register is ignored.

SAR																															

Bit Range	Default & Access	Description
31:0	0h RW	**SAR:** Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

21.15.68 reg_LLP_type (LLP5)—Offset 1C8h

Note: You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled The LLP register has two functions: The logical result of the equation LLP.LOC != 0 is used to set up the type of DMA transfer-single or multi-block. Table shows how the method of updating the channel registers is a function of LLP.LOC != 0. If LLP.LOC is set to 0x0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type. LLP.LOC != 0 contains the pointer to the next LLI for block chaining using linked lists, The LLPx register can also point to the address where write-back of the control and source/destination status information occur after block completion.

31:29	0h RW	**CH_CLASS:** Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below

Bit Range	Default & Access	Description
28:18	0h RW	**CH_WEIGHT:** Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to (2^11-1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	**DONE:** If status write-back is enabled, the upper word of the control register, CTL_HIn, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	**BLOCK_TS:** Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesnt mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to (2^17 -1) = (128 KB - 1).

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. Bit Range	Default & Access	Description
31:0	0h RW	**SAR:** Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

21.15.81 reg_LLP_type (LLP6)—Offset 220h

Note: You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled The LLP register has two functions: The logical result of the equation LLP.LOC != 0 is used to set up the type of DMA transfer-single or multi-block. Table shows how the method of updating the channel registers is a function of LLP.LOC != 0. If LLP.LOC is set to 0x0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type. LLP.LOC != 0 contains the pointer to the next LLI for block chaining using linked lists, The LLPx register can also point to the address where write-back of the control and source/destination status information occur after block completion.

21.15.83 reg_CTL_HI_type (CTL_HI6)—Offset 22Ch

This register contains fields that control the DMA transfer. The CTL_HI register is part of the block descriptor (linked list item - LLI) when block chaining is enabled. It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled.If status write-back is enabled, CTL_HI is written to then control registers location of the LLI in system memory at the end of the block transfer.

CH_CLASS			CH_WEIGHT											DONE	BLOCK_TS																

Bit Range	Default & Access	Description
31:29	0h RW	**CH_CLASS:** Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below

Bit Range	Default & Access	Description
28:18	0h RW	**CH_WEIGHT:** Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to (2^11-1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	**DONE:** If status write-back is enabled, the upper word of the control register, CTL_HIn, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	**BLOCK_TS:** Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesnt mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to (2^17 -1) = (128 KB - 1).

21.15.84 reg_SSTAT_type (SSTAT6)—Offset 230h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. SAR																															

Bit Range	Default & Access	Description
31:0	0h RW	**SAR:** Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

21.15.93 reg_DAR_type (DAR7)—Offset 270h

The starting destination address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the destination address of the current transfer.

DAR																															

Bit Range	Default & Access	Description
31:0	0h RW	**DAR:** Current Destination Address of DMA transfer. Updated after each destination transfer. The DINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every destination transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated destination transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Write Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Write address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA write was a burst write (i.e. burst length) 1), the read-back value reflects the first address of the burst write since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA write progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

21.15.94 reg_LLP_type (LLP7)—Offset 278h

Note: You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled The LLP register has two functions: The logical result of the equation LLP.LOC != 0 is used to set up the type of DMA transfer-single or multi-block. Table shows how the method of updating the channel registers is a function of LLP.LOC != 0. If LLP.LOC is set to 0x0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type. LLP.LOC != 0 contains the pointer to the next LLI for block chaining using linked lists, The LLPx register can also point to the address where write-back of the control and source/destination status information occur after block completion.

CH_CLASS	CH_WEIGHT	DONE	BLOCK_TS

Bit Range	Default & Access	Description
31:29	0h RW	**CH_CLASS:** Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below

Bit Range	Default & Access	Description
28:18	0h RW	**CH_WEIGHT:** Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to (2^11-1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	**DONE:** If status write-back is enabled, the upper word of the control register, CTL_HIn, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	**BLOCK_TS:** Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesnt mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to (2^17 -1) = (128 KB - 1).

21.15.103 reg_SGR_type (SGR7)—Offset 2B0h

The Source Gather register contains two fields: Source gather count field (SGRx.SGC). Specifies the number of contiguous source transfers of CTLx.SRC_TR_WIDTH between successive gather intervals. This is defined as a gather boundary. Source gather interval field (SGRx.SGI). Specifies the source address increment/decrement in multiples of CTLx.SRC_TR_WIDTH on a gather boundary when gather mode is enabled for the source transfer. The CTLx.SINC field controls whether the address increments or decrements. When the CTLx.SINC field indicates a fixed-address control, then the address remains constant throughout the transfer and the SGRx register is ignored.

The Destination Scatter register contains two fields: Destination scatter count field (DSRx.DSC) . Specifies the number of contiguous destination transfers of CTLx.DST_TR_WIDTH between successive scatter boundaries. Destination scatter interval field (DSRx.DSI) . Specifies the destination address increment/decrement in multiples of CTLx.DST_TR_WIDTH on a scatter boundary when scatter mode is enabled for the destination transfer. 21.15.115 reg_Mask_type (MaskTfr)—Offset 310h

The contents of the Raw Status registers are masked with the contents of the Mask registers: MaskBlock, MaskDstTran, MaskErr, MaskSrcTran, and MaskTfr. Each Interrupt Mask register has a bit allocated per channel, for example, MaskTfr(2) is the mask bit for the Channel 2 transfer complete interrupt. When the source peripheral of DMA channel i is memory, then the source transaction complete interrupt, MaskSrcTran(i), must be masked to prevent an erroneous triggering of an interrupt on the int_combined signal. Similarly, when the destination peripheral of DMA channel i is memory, then the destination transaction complete interrupt, MaskDstTran(i), must be masked to prevent an erroneous triggering of an interrupt on the int_combined(_n) signal. A channel INT_MASK bit will be written only if the corresponding mask write enable bit in the INT_MASK_WE field is asserted on the same OCP write transfer. This allows software to set a mask bit without performing a read-modified write operation. For example, writing hex 01x1 to the MaskTfr register writes a 1 into MaskTfr(0), while MaskTfr(7:1) remains unchanged. Writing hex 00xx leaves MaskTfr(7:0) unchanged.

Writing a 1 to any bit in these registers unmasks the corresponding interrupt, thus allowing the DMA to set the appropriate bit in the Status registers and int_* port signals.

21.15.126 reg_DmaCfgReg_type (DmaCfgReg)—Offset 398h

This register is used to enable the DMA, which must be done before any channel activity can begin. If the global channel enable bit is cleared while any channel is still active, then DmaCfgReg.DMA_EN still returns 1 to indicate that there are channels still active until hardware has terminated all activity on all channels, at which point the DmaCfgReg.DMA_EN bit returns 0.

21.15.127 reg_ChEnReg_type (ChEnReg)—Offset 3A0h

This is the DMA Channel Enable Register. If software needs to set up a new channel, then it can read this register in order to find out which channels are currently inactive, it can then enable an inactive channel with the required priority. All bits of this register are cleared to 0 when the global DMA channel enable bit, DmaCfgReg(0), is 0. When the global channel enable bit is 0, then a write to the ChEnReg register is ignored and a read will always read back 0. The channel enable bit, ChEnReg.CH_EN, is written only if the corresponding channel write enable bit, ChEnReg.CH_EN_WE, is asserted on the same OCP write transfer. For example, writing hex 01x1 writes a 1 into ChEnReg(0), while ChEnReg(7:1) remains unchanged. Writing hex 00xx leaves ChEnReg(7:0) unchanged. Note that a read-modified write is not required.

Software can therefore poll this bit to determine when this channel is free for a new DMA transfer.

21.16.1 reg_SAR_type (SAR0)—Offset 0h

The starting source address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the source address of the current transfer.

SAR																															

Bit Range	Default & Access	Description
31:0	0h RW	**SAR:** Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

21.16.2 reg_DAR_type (DAR0)—Offset 8h

The starting destination address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the destination address of the current transfer.

However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Write Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Write address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA write was a burst write (i.e. burst length) 1), the read-back value reflects the first address of the burst write since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. 21.16.3 reg_LLP_type (LLP0)—Offset 10h

Note: You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled The LLP register has two functions: The logical result of the equation LLP.LOC != 0 is used to set up the type of DMA transfer-single or multi-block. Table shows how the method of updating the channel registers is a function of LLP.LOC != 0. If LLP.LOC is set to 0x0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type. LLP.LOC != 0 contains the pointer to the next LLI for block chaining using linked lists, The LLPx register can also point to the address where write-back of the control and source/destination status information occur after block completion.

CH_CLASS | CH_WEIGHT | DONE | BLOCK_TS

Bit Range	Default & Access	Description
31:29	0h RW	**CH_CLASS:** Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below

Bit Range	Default & Access	Description
28:18	0h RW	**CH_WEIGHT:** Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to (2^11-1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	**DONE:** If status write-back is enabled, the upper word of the control register, CTL_HIn, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	**BLOCK_TS:** Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesnt mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to (2^17 -1) = (128 KB - 1).

21.16.6 reg_SSTAT_type (SSTAT0)—Offset 20h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. Note : This register is a temporary placeholder for the source status information on its way to the SSTATx register location of the LLI. 21.16.12 reg_SGR_type (SGR0)—Offset 48h

The Source Gather register contains two fields: Source gather count field (SGRx.SGC). Specifies the number of contiguous source transfers of CTLx.SRC_TR_WIDTH between successive gather intervals. This is defined as a gather boundary. Source gather interval field (SGRx.SGI). Specifies the source address increment/decrement in multiples of CTLx.SRC_TR_WIDTH on a gather boundary when gather mode is enabled for the source transfer. The CTLx.SINC field controls whether the address increments or decrements. SAR																															

Bit Range	Default & Access	Description
31:0	0h RW	**SAR:** Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

21.16.15 reg_DAR_type (DAR1)—Offset 60h

The starting destination address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the destination address of the current transfer.

DAR																															

Bit Range	Default & Access	Description
31:0	0h RW	**DAR:** Current Destination Address of DMA transfer. Updated after each destination transfer. The DINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every destination transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated destination transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Write Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Write address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA write was a burst write (i.e. burst length) 1), the read-back value reflects the first address of the burst write since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA write progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

21.16.16 reg_LLP_type (LLP1)—Offset 68h

Note: You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled The LLP register has two functions: The logical result of the equation LLP.LOC != 0 is used to set up the type of DMA transfer-single or multi-block. Table shows how the method of updating the channel registers is a function of LLP.LOC != 0. If LLP.LOC is set to 0x0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type. LLP.LOC != 0 contains the pointer to the next LLI for block chaining using linked lists, The LLPx register can also point to the address where write-back of the control and source/destination status information occur after block completion.

CH_CLASS | CH_WEIGHT | DONE | BLOCK_TS

Bit Range	Default & Access	Description
31:29	0h RW	**CH_CLASS:** Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below

Bit Range	Default & Access	Description
28:18	0h RW	**CH_WEIGHT:** Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to (2^11-1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	**DONE:** If status write-back is enabled, the upper word of the control register, CTL_HIn, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	**BLOCK_TS:** Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesnt mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to (2^17 -1) = (128 KB - 1).

21.16.19 reg_SSTAT_type (SSTAT1)—Offset 78h

21.16.25 reg_SGR_type (SGR1)—Offset A0h

The Source Gather register contains two fields: Source gather count field (SGRx.SGC). Specifies the number of contiguous source transfers of CTLx.SRC_TR_WIDTH between successive gather intervals. This is defined as a gather boundary. Source gather interval field (SGRx.SGI). Specifies the source address increment/decrement in multiples of CTLx.SRC_TR_WIDTH on a gather boundary when gather mode is enabled for the source transfer. The CTLx.SINC field controls whether the address increments or decrements. When the CTLx.SINC field indicates a fixed-address control, then the address remains constant throughout the transfer and the SGRx register is ignored.

SAR																															

Bit Range	Default & Access	Description
31:0	0h RW	**SAR:** Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

21.16.29 reg_LLP_type (LLP2)—Offset C0h

Note: You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled The LLP register has two functions: The logical result of the equation LLP.LOC != 0 is used to set up the type of DMA transfer-single or multi-block. Table shows how the method of updating the channel registers is a function of LLP.LOC != 0. If LLP.LOC is set to 0x0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type. LLP.LOC != 0 contains the pointer to the next LLI for block chaining using linked lists, The LLPx register can also point to the address where write-back of the control and source/destination status information occur after block completion.

Fields: CH_CLASS, CH_WEIGHT, DONE, BLOCK_TS

Bit Range	Default & Access	Description
31:29	0h RW	**CH_CLASS:** Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below

Bit Range	Default & Access	Description
28:18	0h RW	**CH_WEIGHT:** Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to (2^11-1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	**DONE:** If status write-back is enabled, the upper word of the control register, CTL_HIn, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	**BLOCK_TS:** Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesnt mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to (2^17 -1) = (128 KB - 1).

21.16.32 reg_SSTAT_type (SSTAT2)—Offset D0h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. Note : This register is a temporary placeholder for the source status information on its way to the SSTATx register location of the LLI. The Source Gather register contains two fields: Source gather count field (SGRx.SGC). Specifies the number of contiguous source transfers of CTLx.SRC_TR_WIDTH between successive gather intervals. This is defined as a gather boundary. Source gather interval field (SGRx.SGI). Specifies the source address increment/decrement in multiples of CTLx.SRC_TR_WIDTH on a gather boundary when gather mode is enabled for the source transfer. The CTLx.SINC field controls whether the address increments or decrements. When the CTLx.SINC field indicates a fixed-address control, then the address remains constant throughout the transfer and the SGRx register is ignored.

31:0	0h RW	**SAR:** Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

21.16.42 reg_LLP_type (LLP3)—Offset 118h

Note: You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled The LLP register has two functions: The logical result of the equation LLP.LOC != 0 is used to set up the type of DMA transfer-single or multi-block. Table shows how the method of updating the channel registers is a function of LLP.LOC != 0. If LLP.LOC is set to 0x0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type. LLP.LOC != 0 contains the pointer to the next LLI for block chaining using linked lists, The LLPx register can also point to the address where write-back of the control and source/destination status information occur after block completion.

CH_CLASS | CH_WEIGHT | DONE | BLOCK_TS

Bit Range	Default & Access	Description
31:29	0h RW	**CH_CLASS:** Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below

Bit Range	Default & Access	Description
28:18	0h RW	**CH_WEIGHT:** Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to (2^11-1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	**DONE:** If status write-back is enabled, the upper word of the control register, CTL_HIn, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	**BLOCK_TS:** Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesnt mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to (2^17 -1) = (128 KB - 1).

21.16.51 reg_SGR_type (SGR3)—Offset 150h

The Source Gather register contains two fields: Source gather count field (SGRx.SGC). Specifies the number of contiguous source transfers of CTLx.SRC_TR_WIDTH between successive gather intervals. This is defined as a gather boundary. Source gather interval field (SGRx.SGI). Specifies the source address increment/decrement in multiples of CTLx.SRC_TR_WIDTH on a gather boundary when gather mode is enabled for the source transfer. The CTLx.SINC field controls whether the address increments or decrements. When the CTLx.SINC field indicates a fixed-address control, then the address remains constant throughout the transfer and the SGRx register is ignored.

SAR																															

Bit Range	Default & Access	Description
31:0	0h RW	**SAR:** Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

21.16.55 reg_LLP_type (LLP4)—Offset 170h

Note: You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled The LLP register has two functions: The logical result of the equation LLP.LOC != 0 is used to set up the type of DMA transfer-single or multi-block. Table shows how the method of updating the channel registers is a function of LLP.LOC != 0. If LLP.LOC is set to 0x0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type. LLP.LOC != 0 contains the pointer to the next LLI for block chaining using linked lists, The LLPx register can also point to the address where write-back of the control and source/destination status information occur after block completion.

CH_CLASS | CH_WEIGHT | DONE | BLOCK_TS

Bit Range	Default & Access	Description
31:29	0h RW	**CH_CLASS:** Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below

Bit Range	Default & Access	Description
28:18	0h RW	**CH_WEIGHT:** Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to (2^11-1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	**DONE:** If status write-back is enabled, the upper word of the control register, CTL_HIn, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	**BLOCK_TS:** Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesnt mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to (2^17 -1) = (128 KB - 1).

21.16.58 reg_SSTAT_type (SSTAT4)—Offset 180h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. Note : This register is a temporary placeholder for the source status information on its way to the SSTATx register location of the LLI. The source status information should be retrieved by software from the SSTATx register location of the LLI, and not by a read of this register over the DMA slave interface.

21.16.64 reg_SGR_type (SGR4)—Offset 1A8h

The Source Gather register contains two fields: Source gather count field (SGRx.SGC). Specifies the number of contiguous source transfers of CTLx.SRC_TR_WIDTH between successive gather intervals. This is defined as a gather boundary. Source gather interval field (SGRx.SGI). Specifies the source address increment/decrement in multiples of CTLx.SRC_TR_WIDTH on a gather boundary when gather mode is enabled for the source transfer. The CTLx.SINC field controls whether the address increments or decrements. When the CTLx.SINC field indicates a fixed-address control, then the address remains constant throughout the transfer and the SGRx register is ignored.

SAR																															

Bit Range	Default & Access	Description
31:0	0h RW	**SAR:** Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

21.16.68 reg_LLP_type (LLP5)—Offset 1C8h

Note: You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled The LLP register has two functions: The logical result of the equation LLP.LOC != 0 is used to set up the type of DMA transfer-single or multi-block. Table shows how the method of updating the channel registers is a function of LLP.LOC != 0. If LLP.LOC is set to 0x0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type. LLP.LOC != 0 contains the pointer to the next LLI for block chaining using linked lists, The LLPx register can also point to the address where write-back of the control and source/destination status information occur after block completion.

BURST_SIZE = (2 ^ MSIZE) 1.Transferred Bytes Per Burst = (BURST_SIZE * TR_WIDTH) 2.For incrementing addresses and (Transfer_Width (4 Bytes), the MSIZE parameter is ignored since only single transactions are supported (due to OCP limitations) Table 5-2 lists the decoding for this field. For a non-memory peripheral, this is typically the peripheral (source) FIFO width.
0	0h RW	**INT_EN:** Interrupt Enable Bit. If set, then all interrupt-generating sources are enabled.

21.16.70 reg_CTL_HI_type (CTL_HI5)—Offset 1D4h

This register contains fields that control the DMA transfer. The CTL_HI register is part of the block descriptor (linked list item - LLI) when block chaining is enabled. It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled.If status write-back is enabled, CTL_HI is written to then control registers location of the LLI in system memory at the end of the block transfer.

CH_CLASS | CH_WEIGHT | DONE | BLOCK_TS

Bit Range	Default & Access	Description
31:29	0h RW	**CH_CLASS:** Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below

Bit Range	Default & Access	Description
28:18	0h RW	**CH_WEIGHT:** Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to (2^11-1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	**DONE:** If status write-back is enabled, the upper word of the control register, CTL_HIn, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	**BLOCK_TS:** Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesnt mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to (2^17 -1) = (128 KB - 1).

21.16.71 reg_SSTAT_type (SSTAT5)—Offset 1D8h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. SAR																															

Bit Range	Default & Access	Description
31:0	0h RW	**SAR:** Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

21.16.81 reg_LLP_type (LLP6)—Offset 220h

Note: You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled The LLP register has two functions: The logical result of the equation LLP.LOC != 0 is used to set up the type of DMA transfer-single or multi-block. Table shows how the method of updating the channel registers is a function of LLP.LOC != 0. If LLP.LOC is set to 0x0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type. LLP.LOC != 0 contains the pointer to the next LLI for block chaining using linked lists, The LLPx register can also point to the address where write-back of the control and source/destination status information occur after block completion.

CH_CLASS			CH_WEIGHT											DONE	BLOCK_TS																

Bit Range	Default & Access	Description
31:29	0h RW	**CH_CLASS:** Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below

Bit Range	Default & Access	Description
28:18	0h RW	**CH_WEIGHT:** Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to (2^11-1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	**DONE:** If status write-back is enabled, the upper word of the control register, CTL_HIn, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	**BLOCK_TS:** Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesnt mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to (2^17 -1) = (128 KB - 1).

21.16.84 reg_SSTAT_type (SSTAT6)—Offset 230h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. Note : This register is a temporary placeholder for the source status information on its way to the SSTATx register location of the LLI. 21.16.90 reg_SGR_type (SGR6)—Offset 258h

The Source Gather register contains two fields: Source gather count field (SGRx.SGC). Specifies the number of contiguous source transfers of CTLx.SRC_TR_WIDTH between successive gather intervals. This is defined as a gather boundary. Source gather interval field (SGRx.SGI). Specifies the source address increment/decrement in multiples of CTLx.SRC_TR_WIDTH on a gather boundary when gather mode is enabled for the source transfer. The CTLx.SINC field controls whether the address increments or decrements. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

21.16.93 reg_DAR_type (DAR7)—Offset 270h

The starting destination address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the destination address of the current transfer.

21.16.94 reg_LLP_type (LLP7)—Offset 278h

Note: You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled The LLP register has two functions: The logical result of the equation LLP.LOC != 0 is used to set up the type of DMA transfer-single or multi-block. Table shows how the method of updating the channel registers is a function of LLP.LOC != 0. If LLP.LOC is set to 0x0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type. LLP.LOC != 0 contains the pointer to the next LLI for block chaining using linked lists, The LLPx register can also point to the address where write-back of the control and source/destination status information occur after block completion.

31:29	0h RW	**CH_CLASS:** Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below

Bit Range	Default & Access	Description
28:18	0h RW	**CH_WEIGHT:** Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to (2^11-1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	**DONE:** If status write-back is enabled, the upper word of the control register, CTL_HIn, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	**BLOCK_TS:** Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesnt mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to (2^17 -1) = (128 KB - 1).

21.16.97 reg_SSTAT_type (SSTAT7)—Offset 288h

The channel can then communicate with the source peripheral connected to that interface through the assigned hardware handshaking interface. NOTE: For correct DMA operation, only one peripheral (source or destination) should be assigned to the same handshaking interface. The Source Gather register contains two fields: Source gather count field (SGRx.SGC). Specifies the number of contiguous source transfers of CTLx.SRC_TR_WIDTH between successive gather intervals. This is defined as a gather boundary. Source gather interval field (SGRx.SGI). Specifies the source address increment/decrement in multiples of CTLx.SRC_TR_WIDTH on a gather boundary when gather mode is enabled for the source transfer. The CTLx.SINC field controls whether the address increments or decrements. When the CTLx.SINC field indicates a fixed-address control, then the address remains constant throughout the transfer and the SGRx register is ignored.

21.16.115 reg_Mask_type (MaskTfr)—Offset 310h

The contents of the Raw Status registers are masked with the contents of the Mask registers: MaskBlock, MaskDstTran, MaskErr, MaskSrcTran, and MaskTfr. Each Interrupt Mask register has a bit allocated per channel, for example, MaskTfr(2) is the mask bit for the Channel 2 transfer complete interrupt. When the source peripheral of DMA channel i is memory, then the source transaction complete interrupt, MaskSrcTran(i), must be masked to prevent an erroneous triggering of an interrupt on the int_combined signal. Similarly, when the destination peripheral of DMA channel i is memory, then the destination transaction complete interrupt, MaskDstTran(i), must be masked to prevent an erroneous triggering of an interrupt on the int_combined(_n) signal. A channel INT_MASK bit will be written only if the corresponding mask write enable bit in the INT_MASK_WE field is asserted on the same OCP write transfer. This allows software to set a mask bit without performing a read-modified write operation. For example, writing hex 01x1 to the MaskTfr register writes a 1 into MaskTfr(0), while MaskTfr(7:1) remains unchanged. Writing hex 00xx leaves MaskTfr(7:0) unchanged.

Writing a 1 to any bit in these registers unmasks the corresponding interrupt, thus allowing the DMA to set the appropriate bit in the Status registers and int_* port signals.

21.16.126 reg_DmaCfgReg_type (DmaCfgReg)—Offset 398h

This register is used to enable the DMA, which must be done before any channel activity can begin. If the global channel enable bit is cleared while any channel is still active, then DmaCfgReg.DMA_EN still returns 1 to indicate that there are channels still active until hardware has terminated all activity on all channels, at which point the DmaCfgReg.DMA_EN bit returns 0.

21.16.127 reg_ChEnReg_type (ChEnReg)—Offset 3A0h

This is the DMA Channel Enable Register. If software needs to set up a new channel, then it can read this register in order to find out which channels are currently inactive, it can then enable an inactive channel with the required priority. All bits of this register are cleared to 0 when the global DMA channel enable bit, DmaCfgReg(0), is 0. When the global channel enable bit is 0, then a write to the ChEnReg register is ignored and a read will always read back 0. The channel enable bit, ChEnReg.CH_EN, is written only if the corresponding channel write enable bit, ChEnReg.CH_EN_WE, is asserted on the same OCP write transfer. For example, writing hex 01x1 writes a 1 into ChEnReg(0), while ChEnReg(7:1) remains unchanged. Writing hex 00xx leaves ChEnReg(7:0) unchanged. Note that a read-modified write is not required.

Software can therefore poll this bit to determine when this channel is free for a new DMA transfer.

22 Intel® Trusted Execution Engine (TXE)

This section describes the security components and capabilities of the Intel® Trusted Execution Engine (TXE) security co-processor.

Note: TXE firmware is required on the Bay Trail Platform as part of the PCU SPI flash image. PCU SPI must be setup in descriptor mode. For security reasons, primarily to lock PCU SPI flash access permission and OTP fue programming, TXE Manufacturing Mode must be Disabled before shipping to customers. See your Intel® representative for details.

22.1 Features

22.1.1 Security Feature

The Intel® TXE is a security co-processor responsible for supporting and handling security. Features include:

- 32-bit RISC processor
- 256KB Data/Code RAM accessible only to the Intel® TXE
- 128KB On Chip Mask ROM for storage of Intel® TXE code
- Common Timer 1-100 µS granularity, configurable interrupt (under FW control)
- Inter-Processor Communication for message passing between the Host CPU and Intel® TXE
- 64 byte input and output command buffers
- 256 byte shared payload (enables 2048-bit keys to be exchanged as part of the command)
- No Host CPU address domain access to the Intel® TXE address domain by any Host CPU address domain units
- Security controller has direct access to Host CPU address domain (Some Restrictions Apply). Multiple context DMA engine to transfer data between Host CPU address domain (System memory) and the Intel® TXE; programmable by the Intel® TXE CPU only.
- One multi-tiered FW Key Ladder and one Intel Key ladder.
- Paging DMA operations includes encryption/decryption and integrity check value (ICV) calculation. Auxiliary GPIOs to support input alert and two GP Outputs.

22.1.1.1 HW Accelerators

- DES/3DES (ECB, CBC) – 128b ABA key for 3DES Key Ladder Operations
- Three AES engines - Two fast -128 and one slow- 128/256

- Exponentiation Acceleration Unit (EAU) for modular exponentiation, modular reduction, large number addition, subtraction, and multiplication
- SHA1, SHA256/384/512, MD5

22.1.1.2 FW Utilities and Ciphers

- RSA (with EAU acceleration)
- Flash Write Enable/Disable
- Comprehensive IPC Command Set
- Chip Unique Key encryption key wrapping of other platform keys (Flash)

22.1.1.3 Downloadable FW Utilities and Ciphers

- Integrated Theft Deterrence Technology - Intel® Anti-Theft Technology (Intel® AT)
- Media Vault - content protection and distribution product specifically focused on online content for streaming and download
- One Time Programmable (OTP)

22.2 Register Map

Bits	Field
31:23	DEVICEID_SETID
22:20	DEVICEID_CONST
19:16	DEVICEID_FUSE
15:0	VENDORID

Bit Range	Default & Access	Field Name (ID): Description
31:23	X RO	**DEVICEID_SETID:** DIDH: Identifier assigned to the Device 26 SEC PCI device. Bits[31:23] of this register are obtained from SETID message sent by PMC
22:20	001b RO	**DEVICEID_CONST:** DIDM: Identifier assigned to the Device 26 SEC PCI device. Bits[22:20] of this register are strapped at SEC top level
19:16	X RO	**DEVICEID_FUSE[(DEVICEID_FUSE):** DIDL: Identifier assigned to the Device 26 SEC PCI device. Bits[19:16] of this register are determined by fuses
15:0	8086h RO	**VENDORID:** VID: PCI standard identification for Intel

22.3.2 Status Command (STATUSCOMMAND)—Offset 4h

Status Command. Register acces control: FW=RO PMC=RW Host=RW

Access Method

Type: PCI Configuration Register (Size: 32 bits)	**Offset:** [B:0, D:26, F:0] + 4h

Default: 00100000h

Bit Range	Default & Access	Field Name (ID): Description
31	0b NA	**RESERVED (RSVD_31_31):** RESERVED BITS
30	X RW/C	**SIGNALED_SYSTEM_ERROR_30:** SERR status, write 1 to clear.
29	X RW/C	**RMA:** SERR status, write 1 to clear.
28:21	0b NA	**RESERVED (RSVD_28_21):** RESERVED BITS
20	1b RO	**CAPLIST:** CAP: Indicates that the CAPPOINT register at 34h provides an offset into PCI Configuration Space containing a pointer to the location of the first item in the list
19	X RO	**INTR_STATUS:** IS: Reflects the state of the interrupt in the graphics device. Is set to 1 if interrupt (as determined by IIR and IER memory interface registers) is set to 1. Otherwise is set to 0
18:11	0b NA	**RESERVED (RSVD_18_11):** RESERVED BITS
10	X RW	**INTR_DISABLE:** ID: When 1, blocks the sending of a MSI interrupt and blocks the sending of a Message bus interrupt. The interrupt status is not blocked from being reflected in COMMANDSTATUS. INTR_STT. When 0, permits the sending of a MSI interrupt or Message bus interrupt. Note: Overall, a MSI interrupt is sent when the expression (COMMANDSTATUS. INTR_STT and ~COMMANDSTATUS. INTR_DIS and COMMANDSTATUS.BUS_MSTR_EN and MSI_CAPID.MSI_EN) changes from 0 to 1. Overall, a Message bus interrupt assert is sent when the expression (COMMANDSTATUS. INTR_STT and ~COMMANDSTATUS. INTR_DIS and ~MSI_CAPID.MSI_EN) changes from 0 to 1. The corresponding Message bus interrupt de-assert is sent when the expression (COMMANDSTATUS. INTR_STT and ~COMMANDSTATUS. INTR_DIS and ~MSI_CAPID.MSI_EN) changes from 1 to 0
9	0b NA	**RESERVED (RSVD_9_9):** RESERVED BITS
8	X RW	**INTR_STATUS (SERR_EN_8):** SERR enable.
7:3	0b NA	**RESERVED (RSVD_7_3):** RESERVED BITS
2	X RW	**BME:** BME: Enables GVD to function as a PCI compliant master. When 0, blocks the sending of MSI interrupts and DDR transactions. When 1, permits the sending of MSI interrupts and DDR transactions. Note: transactions to SEC paging IMR are not controlled (enabled/disabled) by this field
1	X RW	**MSE:** MSE: When set, accesses to this device's memory space is enabled. When 1, SEC will compare IOSF primary address MS bits with its BARs MS bits. If there is a match and if the IOSF command is either a MEMRD or MEMWR, SEC send the command to the destination pointed by the base address. Care should be taken in setting up SEC BARs that more than 1 match is not made as this will result in unpredictable behavior. When 0, the SEC will not select a MEMRD or MEMWR IOSF command
0	0b NA	**RESERVED (RSVD_0_0):** IOSE: Since SEC doesn't have I/O space, this bit is hard coded to 0. RESERVED BITS

22.3.3 Revision ID and Class Code (REVCLASSCODE)—Offset 8h

Revision ID and Class Code. Register acces control: FW=RO PMC=RW Host=RW

Access Method

Type: PCI Configuration Register (Size: 32 bits)   **Offset:** [B:0, D:26, F:0] + 8h

Default: 10800000h

22.3.4 CLLATHEADERBISTR (CLLATHEADERBIST)—Offset Ch

PCI Cache Line Size, Latancy Timer, Header Type and BIST register. Register acces control: FW=RO PMC=RW Host=RW

Access Method

Type: PCI Configuration Register (Size: 32 bits) **Offset:** [B:0, D:26, F:0] + Ch

Default: 00000000h

22.3.5 SAP Agent Memory BAR (SAPAGENTBAR)—Offset 10h

Memory Bar of the SAP Agent. Request to this BAR will be directed to the SAP. Register acces control: FW=RO PMC=RW Host=RW

Access Method

Type: PCI Configuration Register (Size: 32 bits) **Offset:** [B:0, D:26, F:0] + 10h

Default: 00000000h

22.3.6 Bridge Memory BAR (BRIDGEBAR)—Offset 14h

Memory Bar of the IOSF-)SAP Bridge. Request to this BAR will be directed to the Bridge configuration. Register acces control: FW=RO PMC=RW Host=RW

Access Method

Type: PCI Configuration Register (Size: 32 bits) **Offset:** [B:0, D:26, F:0] + 14h

Default: 00000000h

BaseAddressRegion	RSVD_19_0	RESRC_TYP

Bit Range	Default & Access	Field Name (ID): Description
31:20	X RW	**BaseAddressRegion:** BA: Set by the OS, these bits correspond to address signals [31:20]. SEC will compare the IOSF address (bits [31:20]) with SAP_BRIDGE_BAR.BASE_ADDR. If there is a match, and COMMANDSTATUS.MEM_SPC_EN = 1 and the IOSF command is either a MEMRD or MEMWR, SEC will send the command to its MMIO registers block. If there's no MMIO register in the accessed offset, SEC Bridge will send FFFF_FFFFh to indicate a miss on the IOSF bus
19:1	0b NA	**RESERVED (RSVD_19_0):** RESERVED BITS
0	0b RO	**RESRC_TYP:** RTE: Indicates a request for memory space

22.3.7 Dummy BAR[0-3] (DUMMY_BARS[0-3])—Offset 18h, Count 4, Stride 4h

Dummy BAR, Returns zeroes to indicate un-implemented BAR. Register acces control: FW=RO PMC=RW Host=RW

Access Method

Type: PCI Configuration Register (Size: 32 bits)

Offset[0-3]: [B:0, D:26, F:0] + 18h + [0-3]*4h

Default: 00000000h

22.3.8 SUBSYSTEMID—Offset 2Ch

PCI Subsystem Identifiers. Register acces control: FW=RO PMC=RW Host=RW

Access Method

Type: PCI Configuration Register (Size: 32 bits)

Offset: [B:0, D:26, F:0] + 2Ch

Default: 00000000h

SUBSYSTEMID | SUBSYSTEMVENDORID

Bit Range	Default & Access	Field Name (ID): Description
31:16	0b RW	**SUBSYSTEMID:** The value in this field is programmed by the system BIOS. According to the PCI spec, only the BIOS can write it, and only once after reset. After the first write, this register becomes read-only. The content of this register may also be read (not written) from the Device 0 subsystem register address
15:0	0b RW	**SUBSYSTEMVENDORID:** The value in this field is programmed by the system BIOS. According to the PCI spec, only the BIOS can write it, and only once after reset. After the first write, this register becomes read-only. The content of this register may also be read (not written) from the Device 0 subsystem register address

22.3.9 EXPANSION_ROM_BASEADDR—Offset 30h

PCI Expansion ROM - disabled for SEC. Register acces control: FW=RO PMC=RW Host=RW

Access Method

Type: PCI Configuration Register (Size: 32 bits)

Offset: [B:0, D:26, F:0] + 30h

Default: 00000000h

31:0	0b NA	**RESERVED (RSVD_31_0):** RESERVED BITS, Expansion RO is disabled for SEC, therefore this field is hard coded to zero

22.3.10 CAPABILITYPTR—Offset 34h

PCI Capabilities Pointer, points to the next SEC capability which is Power management. Register acces control: FW=RO PMC=RW Host=RW

Access Method

Type: PCI Configuration Register (Size: 32 bits)

Offset: [B:0, D:26, F:0] + 34h

Default: 00000080h

22.3.11 INTERRUPTREG—Offset 3Ch

PCI Interrupt Register. Register acces control: FW=RO PMC=RW Host=RW

Access Method

Type: PCI Configuration Register (Size: 32 bits)

Offset: [B:0, D:26, F:0] + 3Ch

Default: 00000100h

Bit Range	Default & Access	Field Name (ID): Description
31:16	0b NA	**RESERVED (RSVD_31_16):** RESERVED BITS
15:8	01h RO	**INTPIN:** IPIN: Value indicates which interrupt pin this device uses. This field is hard coded to 1h since Cedarview Device 26 is a single function device. The PCI spec requires that it use INTA#
7:0	X RW	**INTLINE:** ILIN: BIOS written value to communicate interrupt line routing information to the device driver

22.3.12 SEC_FW_STS1—Offset 40h

SeC Firmware Status Register 0. SeC FW uses this register in order to report its status to host (e.g. BIOS). Register acces control: FW=RW PMC=RO Host=RO

Access Method

Type: PCI Configuration Register (Size: 32 bits)

Offset: [B:0, D:26, F:0] + 40h

Bit Range	Default & Access	Field Name (ID): Description
31:28	X RW	**INF_PROG_CODE:** This field identifies the infrastructure progress code. For example, when firmware comes out of reset, this field would identify the infrastructure moving from ROM to BRINGUP to Micro Kernel to Policy module, etc. Note that this field is specific to infrastructure and does not represent the entire firmware. Refer to the Working State and Error Code fields to identify current state of the firmware. Values are as follows: 0: ROM. 1: Bringup. 2: uKernel. 3: Policy module. 4: Module loading. 6: Host communication. SeC is up and running, and host communication is established.
27:24	X RW	**CURR_PM_EV:** Status of current SeC power management event. Bit Range	Default & Access	Field Name (ID): Description
31	X RW	**MEM_REQ_VALID:** 1: SeC is making a request for memory, the size of which is indciated by field MEM_SIZE. During early boot stages, BIOS must wait for either this bit to be set or the MEM_REQ_INVALID bit to be set before proceeding.
30	X RW	**MEM_REQ_INVALID:** 1: SeC is not making any request for memory, and MEM_SIZE field should be ignored. During early boot stages, BIOS must wait for either this bit to be set or the MEM_REQ_VALID bit to be set before proceeding.
29:16	X NA	**FUNC_RSVD_29_16:** The functionality of this field is currently reserved
15:0	X RW	**MEM_SIZE:** Memory size that SeC is expecting, in KB. Format is Little Endian (bit 0 least significant, bit 15 most significant).

Bit Range	Default & Access	Field Name (ID): Description
31:28	X RW	**BIOS_MSG_ACK:** DRAM Init Done ACK. 0x00: No ACK was written by SeC. 0x01: ACK was written by SeC.
27:25	X RW	**ACK_DATA:** DRAM Init Done ACK Data. This field contains an action which BIOS should take on receiving an ACK from SeC. 0x00: No DRAM Init Done ACK received. 0x01: Non-power cycle reset. 0x02: Power cycle reset. 0x03: Go to S3. 0x04: Go to S4. 0x05: Go to S5. 0x06: Perform Global Reset. 0x07: Continue to boot.
24	X RW	**FUNC_RSVD_24:** The functionality of this field is currently reserved
23:20	X RW	**SEC_RST_CNT:** Count of SeC Resets
19:16	X RW	**SEC_CURR_OPER_MODE:** The field indicates the firmware mode of operation during this boot cycle. The host must look at this field only after DRAM_INIT_DONE (DID) register based message unless the firmware is in ERR before sending the DID.The Operation Mode doesn't change at runtime. Possible values: 0: Normal. SeC is running in normal mode. 1: Reserved. 2: Debug mode. SeC firmware enters this operation mode when SeC firmware FLASH variable TBD is configured in FLASH to 1. Firmware stays in this mode until the SeC firmware FLASH variable TBD is set to 0. 3: Soft temporary disable. SeC firmware enters this operation mode when BIOS sends the Temporary Disable message to firmware. Firmware stays in this mode until BIOS sends a follow-up message to get SeC out of this mode. Entering this mode is not supported when the system is provisioned with Intel AT firmware. 4: SECOVR_JMPR: SeC firmware enters this operation mode when HDA_SDO asserts high. Asserting the HDA_SDO high on the rising edge of PWROK will also disable SeC and SeC applications. 5: SECOVR_HECI_MSG: SeC firmware enters this operation mode during the firmware image re-flash in the factory environments. BIOS sends the flash protection override message (HMRFPO ENABLE HECI command) and causes a global reset then SeC firmware stays in this state similar to 'Soft Temporary Disable'. Before sending End of Post message (at late POST timeframe), BIOS needs to send a HMRFPO DISABLE command if SECOVR_HECI_MSG is set. In the same boot, the user can flash an image and reset (global reset or G3- exit) the system that will cause firmware to boot with a normal mode.
15:12	X RW	**ERR_CODE:** Set to a nonzero value if the firmware has encountered a fatal error. The firmware has stopped normal operation. Encoding as follows: 0: No error. Firmware is operational in current state. 1: Uncategorized Failure. SeC firmware has experienced an uncategorized error and has disabled itself. Further details of the failure can be found in field FW_STS1.EXT_STAT_DAT. This state can only be exited by powering down or resetting the machine. 2: Reserved. 3: Image Failure. SeC firmware stored in the system flash is not valid. If supported by the platform, the host should program a full firmware image into SeC flash region through the SPI controller. After completion of the SeC flash region update, the host should generate a full system reset the platform (global reset). 4: Debug Failure. Set when more data is available to the firmware on the cause of the failure. Please refer to field FW_STS1.EXT_STAT_DAT_CURR_STATE for more details. 5: Internal ROM Error. 6: Invalid fuse configuration. 7: Failure to access SPI FLASH.
11	X RW	**FW_UPD_IN_PROG:** This bit is set when data migration is required during the Firmware-update process.

Bit Range	Default & Access	Field Name (ID): Description
10	X RW	**FW_BUP_LD_FLR:** This bit is set when firmware is not able to load BRINGUP from the fault tolerant (FT) code. When this bit set, it may or may not have the error code shown in field ERR_CODE. The reason is because the firmware can load BRINGUP from the non fault tolerant (NFT) code.
9	X RW	**FW_INIT_COMP:** When this bit is clear, firmware is still in loading process and has not made it to final steady state yet. When firmware has fully entered a stable state, this bit is set to 1 and 'Current Working State' field of this register provides the steady state of SeC.
8:6	000b RW	**SEC_CURR_OP_STATE:** This field describes the state in which SeC is currently functioning in at this moment. It's the combination of SeC power state and UMA. The field is set only upon entering the true hardware state. Values: 000b: Preboot (default) 001b: M0 with UMA. 010b: MOff. 011b: Reserved. 100b: Reserved. 101b: Reserved. 110b: Bringup. 111b: M0 without UMA but with error. If there is no memory in the system, or upon identifying an error in UMA initialization, the SeC firmware will get into this operation state.
5	X RW	**FPT_BAD:** This bit is set when the firmware discovers a bad checksum of Flash Partition Table (FPT). When this bit set, it may or may not have the error code shown in field ERR_CODE. The system can get this bit clear by flashing the proper firmware image again.
4	X RW	**MANUF_MODE:** When this bit is set, the platform is still in Manufacturing mode. Host can use this bit to inform user that the platform is NOT ready for production yet. This bit is set as long as SeC Manufacturing Mode Done bit is set to 0 or SPI flash descriptor region is not locked. For shipping machine, this bit has to be to 0.
3:0	X RW	**SEC_CURR_WRK_STATE:** This field describes the current working state of the SeC firmware. Further information about the progress within the Current Working State can be found in field SEC_FW_STS1.EXT_STS_DAT. In spoken language, the 'Current Working State' indicates what firmware is doing at this moment. Encoding is as follows: 0: Reset. SeC firmware is in a reset state. 1: Initializing. SeC firmware is initializing, the final functional state is NOT known at this time. 2: Recovery: SeC firmware is recovering from an image update failure. Upon completion of this state, SeC firmware will enter the Initializing State. The firmware will stay in recovery state until a new firmware update is run. 3: Reserved. 4: Reserved. 5: Normal. SeC firmware is operating in normal state. 6: Platform Disable Wait. SeC firmware enters this state when it pauses itself with AT fuses set to halt platform after 30 minutes wait. 7: OP State Transition. SeC firmware sets this state before starting a transition to a new operation state. 8: Reserved.

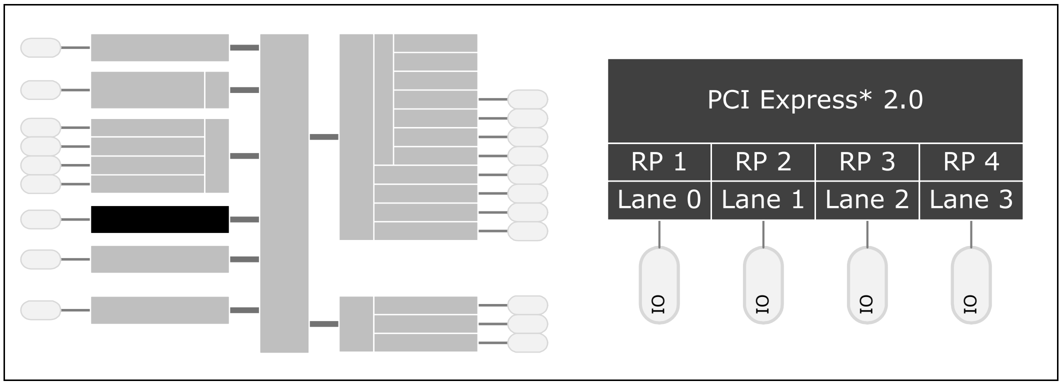
23 PCI Express* 2.0

There are four lanes and up to four PCI Express root ports, each supporting the *PCI Express* Base Specification*, Rev. 2.0 at a maximum 5 GT/s signaling rate. The root ports can be configured to support a diverse set of lane assignments.



23.1 Signal Descriptions

Please see Chapter 2, “Physical Interfaces” for additional details.

The signal description table has the following headings:

- **Signal Name:** The name of the signal/pin
- **Direction**: The buffer direction can be either input, output, or I/O (bidirectional)
- **Platform Power**: The reference power plane.
- **Description**: A brief explanation of the signal’s function

Note: PMC_WAKE_PCIE[3:0]# are not listed, but can be used by PCI Express* devices. Please see Section 30, “PCU – Power Management Controller (PMC)” on page 4344 for details.

Table 240. Signals

Signal Name	Direction Plat. Power	Description
PCIE_TXP[3:0] **PCIE_TXN[3:0]**	O PCIESATA	**PCI Express* Transmit** PCI Express* Ports 3:0 transmit pair (P and N) signals. Each pair makes up the transmit half of a lane.
PCIE_RXP[3:0] **PCIE_RXN[3:0]**	I PCIESATA	**PCI Express* Receive:** PCI Express* Ports 3:0 receive pair (P and N) signals. Each pair makes up the receive half of lane.
PCIE_CLKP[3:0] **PCIE_CLKN[3:0]**	O V1P0S	**PCI Express* Output Clock** 100-MHz differential clock signals. These are not owned by the PCI Express* controller, but are platform clocks found in the Integrated Clock.
PCIE_CLKREQ[3:0]#	I V1P8S	**PCI Express* Clock Request** Used for devices that need to request one of the four output clocks. Each clock request maps to the matching clock output (e.g., PCI_CLKREQ[0] maps to PCIE_CLKP/N[0]). These are not owned by the PCI Express* controller, but are platform clocks found in the Integrated Clock. *These signals are muxed and may be used by other functions.*
PCIE_RCOMP_P **PCIE_RCOMP_N**	I/O	These pins are used to connect the external resistors used for Rcomp. Please contact your Intel representative for details.

23.2 Features

- Conforms to *PCI Express* Base Specification*, Rev. 2.0
- 5.0 or 2.5 GT/s operation per root port
- Virtual Channel support for VC0
- x1, x2 and x4 link widths (auto negotiated)
- Flexible Root Port (1-4) configuration options
  — (4) x1's

— (2) x2's

— (1) x2 plus (2) x1's

— (1) x4

- Interrupts and Events

— Legacy (INTx) and MSI Interrupts

— General Purpose Events

— Express Card Hot Plug Events

— System Error Events

- Power Management

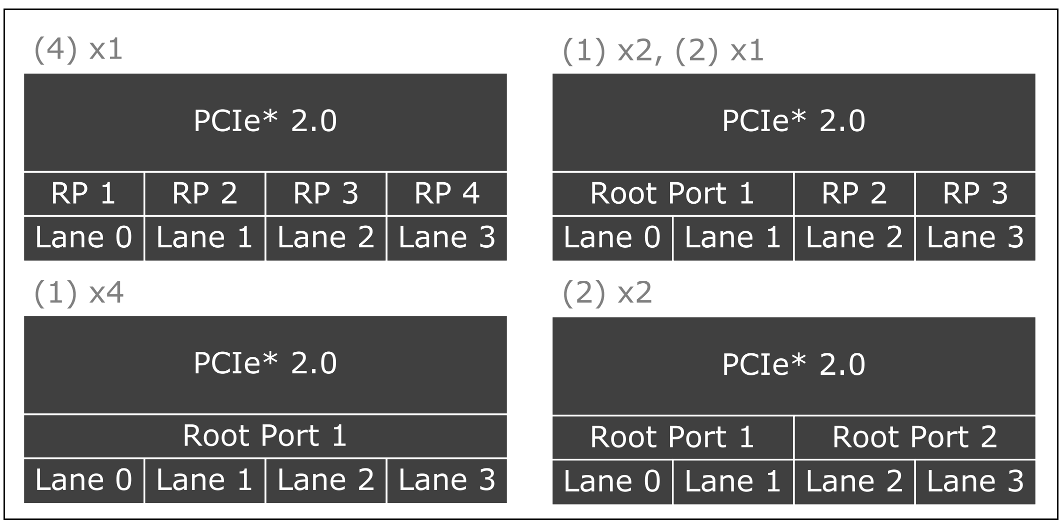
— Link State support for L0s, L1 and L2

— Powered down in ACPI S3 state - L3

23.2.1 Root Port Configurations

Depending on SKU, there are up to four possible lane assignments for root ports 1-4.

Figure 113.Root Port Configuration Options



Root port configurations are set by SoftStraps stored in SPI flash, and the default option is "(4) x1". Links for each root port will train automatically to the maximum possible for each port.

Note: x2 link widths are not common. Most devices will only train to x1 or x4.

Note: PCI functions in PCI configuration space are disabled for root ports not available.

23.2.2 Interrupts and Events

A root port is capable of handling interrupts and events from an end point device. A root port can also generate its own interrupts for some events, including power management and hot plug events, but also including error events.

There are two interrupt types a root port will receive from an end point device: INTx (legacy), and MSI. MSI's are automatically passed upstream by the root port, just as other memory writes would be. INTx messages are delivered to the Legacy block's interrupt router/controller by the root port.

Events and interrupts that are handled by the root port are shown with the possible interrupts they can deliver to the interrupt decoder/router.

Table 241. Possible Interrupts Generated From Events/Packets

Packet/Event	Type	INTx	MSI	SERR	SCI	SMI	GPE
INTx	Packet	X	X				
PM_PME	Packet	X	X				
Power Management (PM)	Event	X	X		X	X	
Hot Plug (HP)	Event	X	X		X	X	
ERR_CORR	Packet			X			
ERR_NONFATAL	Packet			X			
ERR_FATAL	Packet			X			
Internal Error	Event			X			
VDM	Packet						X

Note: Table 241 lists the possible interrupts and events generated based on Packets received, or events generated in the root port. Configuration needed by software to enable the different interrupts as applicable.

When INTx interrupts are received by an end point, they are mapped to the following interrupts and sent to the interrupt decoder/router in the iLB:

Table 242. Interrupt Generated for INT[A-D] Interrupts

	INTA	INTB	INTC	INTD
Root Port 1	INTA#	INTB#	INTC#	INTD#
Root Port 2	INTD#	INTA#	INTB#	INTC#
Root Port 3	INTC#	INTD#	INTA#	INTB#
Root Port 4	INTB#	INTC#	INTD#	INTA#

Note: Interrupts generated from events within the root port are not swizzled.

23.2.2.1 Express Card Hot Plug Events

Express Card Hot Plug is available based on Presence Detection for each root port.

Note: A full Hot Plug Controller is not implemented.

Presence detection occurs when a PCI Express* device is plugged in and power is supplied. The physical layer will detect the presence of the device, and the root port will set the SLSTS.PDS and SLSTS.PDC bits.

When a device is removed and detected by the physical layer, the root port will clear the SLSTS.PDS bit, and set the SLSTS.PDC bit.

Interrupts can be generated by the root port when a hot plug event occurs. A hot plug event is defined as the transition of the SLSTS.PDC bit from 0 to 1. Software can set the SLCTL.PDE and SLTCTL.HPE bits to allow hot plug events to generate an interrupt.

If SLCTL.PDE and SLTCTL.HPE are both set, and STSTS.PDC transitions from 0 to 1, an interrupt will be generated.

23.2.2.2 System Error (SERR)

System Error events are support by both internal and external sources. See the PCI Express* Base Specification, Rev. 2.0 for details.

23.2.3 Power Management

Each root port's link supports L0s, L1, and L2/3 link states per PCI Express* Base Specification, Rev. 2.0. L2/3 is entered on entry to S3.

23.3 References

23.4 Register Map

Each root port supports its own extended PCI bridge header in PCI configuration space. These headers are located on PCI bus 0, device 28, functions 0-3 as shown below. There are no other registers implemented by the root ports or their controller.

See Chapters Chapter 3, "Register Access Methods" and Chapter 4, "Mapping Address Spaces" for additional information.

23.5 PCI Configuration Registers

Registers listed are for function 0 (root port 1). All other root ports contain the same registers. Differences for other root ports (functions 1-3) will be noted in individual registers.

Bit Range	Default & Access	Description
31	0b RW/C	**DPE Detected Parity Error (DPE):** Set when the root port receives a command or data from the backbone with a parity error. This is set even if CMD.PERE is not set.
30	0b RW/C	**Signaled System Error (SSE):** Set when the root port signals a system error to the internal SERR# logic.
29	0b RW/C	**Received Master Abort (RMA):** Set when the root port receives a completion with unsupported request status from the backbone.
28	0b RW/C	**Received Target Abort (RTA):** Set when the root port receives a completion with completer abort from the backbone.
27	0b RW/C	**Signaled Target Abort (STA):** Set whenever the root port forwards a target abort received from the downstream device onto the backbone.
26:25	00b RO	**Primary DEVSEL# Timing Status (PDTS):** Reserved per PCI-Express spec
24	0b RW/C	**Master Data Parity Error Detected (DPD):** Set when the root port receives a completion with a data parity error on the backbone and CMD.PERE is set.
23	0b RO	**Primary Fast Back to Back Capable (PFBC):** Reserved per PCI-Express spec.
22	0b RO	**Reserved (RSVD):** Reserved
21	0b RO	**Primary 66 MHz Capable (PC66):** Reserved per PCI-Express spec.
20	1b RO	**Capabilities List (CLIST):** Indicates the presence of a capabilities list.
19	0b RO/V	**Interrupt Status (IS):** Indicates status of hot plug and power management interrupts on the root port that result in INTx# message generation. This bit is not set if MSI is enabled. If MSI is not enabled, this bit is set regardless of the state of CMD.ID.
18:16	000b RO	**Reserved (RSVD_1):** Reserved
15:11	00h RO	**Reserved (RSVD_2):** Reserved

Bit Range	Default & Access	Description
10	0b RW/V	**Interrupt Disable (ID):** This disables pin-based INTx# interrupts on enabled hot plug and power management events. This bit has no effect on MSI operation. When set, internal INTx# messages will not be generated. When cleared, internal INTx# messages are generated if there is an interrupt for hot plug or power management and MSI is not enabled. This bit does not affect interrupt forwarding from devices connected to the root port. Assert_INTx and Deassert_INTx messages will still be forwarded to the internal interrupt controllers if this bit is set. For PCI Bus Emulation Mode compatibility, if the PCIBEM register is set, this register is RO and returns a value of 0 when read, else it is RW with the functionality described above.
9	0b RO	**Fast Back to Back Enable (FBE):** Reserved per PCI-Express spec.
8	0b RW	**SERR# Enable (SEE):** When set, enables the root port to generate an SERR# message when PSTS.SSE is set.
7	0b RO	**Wait Cycle Control (WCC):** Reserved per PCI-Express spec.
6	0b RW	**Parity Error Response Enable (PERE):** Indicates that the device is capable of reporting parity errors as a master on the backbone.
5	0b RO	**VGA Palette Snoop (VGA_PSE):** Reserved per PCI-Express spec.
4	0b RO	**Memory Write and Invalidate Enable (MWIE):** Reserved per PCI-Express spec.
3	0b RO	**Special Cycle Enable (SCE):** Reserved per PCI-Express and PCI bridge spec.
2	0b RW	**Bus Master Enable (BME):** When set, allows the root port to forward Memory and I/O Read/Write cycles onto the backbone from a PCI-Express device. When this bit is 0b, Memory and I/O requests received at a Root Port must be handled as Unsupported Requests (UR). This bit does not affect forwarding of Completions in either the Upstream or Downstream direction. The forwarding of Requests other than Memory or I/O requests is not controlled by this bit.
1	0b RW	**Memory Space Enable (MSE):** When set, memory cycles within the range specified by the memory base and limit registers can be forwarded to the PCI-Express device. When cleared, these memory cycles are master aborted on the backbone.
0	0b RW	**I/O Space Enable (IOSE):** When set, I/O cycles within the range specified by the I/O base and limit registers can be forwarded to the PCI-Express device. When cleared, these cycles are master aborted on the backbone..

27	0b RW/V	**Discard Timer SERR# Enable (DTSE):** Reserved per PCI-Express spec. For PCI Bus Emulation Mode compatibility, if the DC.PCIBEM register is set, this register is RW else it is RO. This register is only maintained for SW compatibility and has no functionality within the port.
26	0b RO	**Discard Timer Status (DTS):** Reserved per PCI-Express spec. For PCI Bus Emulation Mode compatibility, this register can remain RO as no secondary discard timer exists that will ever cause it to be set.
25	0b RW/V	**Secondary Discard Timer (SDT):** Reserved per Express spec. For PCI Bus Emulation Mode compatibility, if the DC.PCIBEM register is set, this register is RW else it is RO. This register is only maintained for SW compatibility and has no functionality within the port.
24	0b RW/V	**Primary Discard Timer (PDT):** Reserved per Express spec. For PCI Bus Emulation Mode compatibility, if the DC.PCIBEM register is set, this register is RW else it is RO. This register is only maintained for SW compatibility and has no functionality within the port.
23	0b RO	**Fast Back to Back Enable (FBE):** Reserved per Express spec.
22	0b RW	**Secondary Bus Reset (SBR):** Triggers a Hot Reset on the PCI-Express port.
21	0b RW/V	**Master Abort Mode (MAM):** Reserved per Express spec. For PCI Bus Emulation Mode compatibility, if the DC.PCIBEM register is set, this register is RW else it is RO. This register is only maintained for SW compatibility and has no functionality within the port.
20	0b RW	**VGA 16-Bit Decode (V16):** When set, indicates that the I/O aliases of the VGA range (see BCTRL:VE definition below), are not enabled. 0: Execute 10-bit address decode on VGA I/O accesses. 1: Execute 16-bit address decode on VGA I/O accesses.
19	0b RW	**VGA Enable (VE):** When set, the following ranges will be claimed off the backbone by the root port: Memory ranges A0000h-BFFFFh I/O ranges 3B0h 3BBh and 3C0h 3DFh, and all aliases of bits 15:10 in any combination of 1's
18	0b RW	**ISA Enable (IE):** This bit only applies to I/O addresses that are enabled by the I/O Base and I/O Limit registers and are in the first 64KB of PCI I/O space. If this bit is set, the root port will block any forwarding from the backbone to the device of I/O transactions addressing the last 768 bytes in each 1KB block (offsets 100h to 3FFh).
17	0b RW	**SERR# Enable (SE):** When set, ERR_COR, ERR_NONFATAL, and ERR_FATAL messages received are forwarded to the backbone. When cleared, they are not.
16	0b RW	**Parity Error Response Enable (PERE):** When set, poisoned write TLPs and completions indicating poisoned TLPs will set the SSTS.DPD.

Bit Range	Default & Access	Description
15:8	00h RO/V	**Interrupt Pin (IPIN):** Indicates the interrupt pin driven by the root port. At reset, this register takes on the following values, which reflect the reset state of the STRPFUSECFG register in chipset config space: Port Bits[lb]15:12[rb] Bits[lb]11:08[rb] 1 0h STRPFUSECFG.P1IP 2 0h STRPFUSECFG.P2IP 3 0h STRPFUSECFG.P3IP 4 0h STRPFUSECFG.P4IP 5 0h STRPFUSECFG.P5IP 6 0h STRPFUSECFG.P6IP 7 0h STRPFUSECFG.P7IP 8 0h STRPFUSECFG.P8IP The value that is programmed into STRPFUSECFG is always reflected in this register. For PCI Bus Emulation Mode compatibility, if the DC.PCIBEM register is set, this register returns a value of 00h when read, else this register returns the value from the table above.
7:0	00h RW	**Interrupt Line (ILINE):** Software written value to indicate which interrupt line (vector) the interrupt is connected to. No hardware action is taken on this register.

29:25	00h RO	**Interrupt Message Number (IMN):** The root port does not have multiple MSI interrupt numbers.
24	0b RW/O	**Slot Implemented (SI):** Indicates whether the root port is connected to a slot. Slot support is platform specific. BIOS programs this field, and it is maintained until a platform reset.
23:20	4h RO	**Device / Port Type (DT):** Indicates this is a PCI-Express root port
19:16	2h RO	**Capability Version (CV):** Version 2.0 indicates devices compliant to the PCI Express 2.0 specification which incorporates the Register Expansion ECN.
15:8	80h RW/O	**Next Capability (NEXT):** Indicates the location of the next capability. The default value of this register is 80h which points to the MSI Capability structure. BIOS can determine which capabilities will be exposed by including or removing them from the capability linked list. As this register is RWO, BIOS must write a value to this register, even if it is to re-write the default value.
7:0	10h RO	**Capability ID (CID):** Indicates this is a PCI Express capability

31	0b RW/C	**Link Autonomous Bandwidth Status (LABS):** This bit is Set by hardware to indicate that hardware has autonomously changed Link speed or width, without the Port transitioning through DL_Down status, for reasons other than to attempt to correct unreliable Link operation. This bit must be set if the Physical Layer reports a speed or width change was initiated by the Downstream component that was indicated as an autonomous change. The default value of this bit is 0b.
30	0b RW/C	**Link Bandwidth Management Status (LBMS):** This bit is Set by hardware to indicate that either of the following has occurred without the Port transitioning through DL_Down status: - A Link retraining has completed following a write of 1b to the Retrain Link bit Note: This bit is Set following any write of 1b to the Retrain Link bit, including when the Link is in the process of retraining for some other reason. - Hardware has changed Link speed or width to attempt to correct unreliable Link operation, either through an LTSSM timeout or a higher level process This bit must be set if the Physical Layer reports a speed or width change was initiated by the Downstream component that was not indicated as an autonomous change. The default value of this bit is 0b.
29	0b RO/V	**Link Active (LA):** Set to 1b when the Data Link Control and Management State Machine is in the DL_Active state, 0b otherwise.
28	0b RO/V	**Slot Clock Configuration (SCC):** In normal mode, root port uses the same reference clock as on the platform and does not generate its own clock.
27	0b RO/V	**Link Training (LT):** The root port sets this bit whenever link training is occurring, or that 1b was written to the Retrain Link bit but Link training has not yet begun. It clears the bit upon completion of link training.
26	0b RO	**Reserved (RSVD):** Reserved. Previously this was defined as Link Training Error (LTE) but support for this bit was removed from subsequent versions of the PCI Express specification.
25:20	00h RO/V	**Negotiated Link Width (NLW):** For the root ports, this register could take on several values: Port # Value of PN field RPC.PC1 00 01 10 11 1 01h 02h 02h 04h 2 01h 01h 01h 01h 3 01h 01h 02h 01h 4 01h 01h 01h 01h The value of this register is undefined if the link has not successfully trained.

11	0b RW	**Link Autonomous Bandwidth Interrupt Enable (LABIE):** Link Autonomous Bandwidth Interrupt Enable - When Set, this bit enables the generation of an interrupt to indicate that the Link Autonomous Bandwidth Status bit has been Set.
10	0b RW	**Link Bandwidth Management Interrupt Enable (LBMIE):** When Set, this bit enables the generation of an interrupt to indicate that the Link Bandwidth Management Status bit has been Set. This bit is not applicable and is reserved for Endpoints, PCI Express-to-PCI/PCI-X bridges, and Upstream Ports of Switches. Functions that do not implement the Link Bandwidth Notification Capability must hardwire this bit to 0b. Default value of this bit is 0b.
9	0b RW	**Hardware Autonomous Width Disable (HAWD):** When Set, this bit disables hardware from changing the Link width for reasons other than attempting to correct unreliable Link operation by reducing Link width. Default value of this bit is 0b.
8	0b RO	**Enable Clock Power Management (ECPM):** Reserved. Not supported on Root Ports.
7	0b RW	**Extended Synch (ES):** When set, forces extended transmission of FTS ordered sets in FTS and extra TS2 at exit from L1 prior to entering L0.
6	0b RW	**Common Clock Configuration (CCC):** Reserved.

Bit Range	Default & Access	Description
5	0b WO	**Retrain Link (RL):** When set, the root port will train its downstream link. This bit always returns '0' when read. Software uses LSTS.LT to check the status of training. It is permitted to write 1b to this bit while simultaneously writing modified values to other fields in this register. If the LTSSM is not already in Recovery or Configuration, the resulting Link training must use the modified values. If the LTSSM is already in Recovery or Configuration, the modified values are not required to affect the Link training that's already in progress.
4	0b RW	**Link Disable (LD):** When set, the root port will disable the link by directing the LTSSM to the Disabled state.

9:5	00h RO	**Reserved (RSVD_3):** Reserved
4	0b RW	**Completion Timeout Disable (CTD):** When set to 1b, this bit disables the Completion Timeout mechanism. This field is required for all devices that support the Completion Timeout Disable Capability. Software is permitted to set or clear this bit at any time. When set, the Completion Timeout detection mechanism is disabled. If there are outstanding requests when the bit is cleared, it is permitted but not required for hardware to apply the completion timeout mechanism to the outstanding requests. If this is done, it is permitted to base the start time for each request on either the time this bit was cleared or the time each request was issued.
3:0	0h RW	**Completion Timeout Value (CTV):** In Devices that support Completion Timeout programmability, this field allows system software to modify the Completion Timeout value. This field is applicable to Root Ports, Endpoints that issue requests on their own behalf, and PCI Express to PCI/PCI-X Bridges that take ownership of requests issued on PCI Express. For all other devices this field is reserved and must be hardwired to 0000b. A Device that does not support this optional capability must hardwire this field to 0000b and is required to implement a timeout value in the range 50us to 50ms. Devices that support Completion Timeout programmability must support the values given below corresponding to the programmability ranges indicated in the Completion Timeout Values Supported field. The root port targeted configurable ranges are listed below, along with the range allowed by the PCI Express 2.0 specification. Defined encodings: 0000b Default range: 40-50ms (spec range 50us to 50ms) Values available if Range B (10ms to 250ms) programmability range is supported: 0101b 40-50ms (spec range is 16ms to 55ms) 0110b 160-170ms (spec range is 65ms to 210ms) Values available if Range C (250ms to 4s) programmability range is supported: 1001b 400-500ms (spec range is 260ms to 900ms) 1010b 1.6-1.7s (spec range is 1s to 3.5s) Values not defined above are Reserved. Software is permitted to change the value in this field at any time. For requests already pending when the Completion Timeout Value is changed, hardware is permitted to use either the new or the old value for the outstanding requests, and is permitted to base the start time for each request either when this value was changed or when each request was issued.

16	0b RO/V	**Current De-emphasis Level (CDL):** When the Link is operating at 5 GT/s speed, this bit reflects the level of de-emphasis. Encodings: 1b -3.5 dB 0b -6 dB The value in this bit is undefined when the Link is operating at 2.5 GT/s speed.
15:13	000b RO	**Reserved (RSVD_1):** Reserved
12	0b RW/P	**Compliance De-emphasis (CD):** This bit sets the de-emphasis level in Polling.Compliance state if the entry occurred due to the Enter Compliance bit being 1b. Encodings: 1b-3.5 dB 0b-6 dB When the Link is operating at 2.5 GT/s, the setting of this bit has no effect. The default value of this bit is 0b. This bit is intended for debug, compliance testing purposes. System firmware and software is allowed to modify this bit only during debug or compliance testing.
11	0b RW/P	**Compliance SOS (CSOS):** When set to 1b, the LTSSM is required to send SKP Ordered Sets periodically in between the (modified) compliance patterns. The default value of this bit is 0b.

Bit Range	Default & Access	Description
10	0b RW/P	**Enter Modified Compliance (EMC):** When this bit is set to 1b, the device transmits Modified Compliance Pattern if the LTSSM enters Polling.Compliance substate. Default value of this bit is 0b. This register is intended for debug, compliance testing purposes only. System firmware and software is allowed to modify this register only during debug or compliance testing. In all other cases, the system must ensure that this register is set to the default value.
9:7	000b RW/P	**Transmit Margin (TM):** This field controls the value of the nondeemphasized voltage level at the Transmitter pins. This field is reset to 000b on entry to the LTSSM Polling.Configuration substate (see PCI Express Chapter 4 for details of how the Transmitter voltage level is determined in various states). Encodings: 000b Normal operating range 001b 800-1200 mV for full swing and 400-700 mV for half-swing 010b - (n-1) Values must be monotonic with a non-zero slope. The value of n must be greater than 3 and less than 7. At least two of these must be below the normal operating range of n : 200-400 mV for full-swing and 100-200 mV for half-swing n - 111b reserved For a Multi-Function device associated with an Upstream Port, the field in Function 0 is of type RWS, and only Function 0 controls the component's Link behavior. In all other Functions of that device, this field is of type RsvdP. Default value of this field is 000b. Components that support only the 2.5 GT/s speed are permitted to hardwire this bit to 000b. This register is intended for debug, compliance testing purposes only. System firmware and software is allowed to modify this register only during debug or compliance testing. In all other cases, the system must ensure that this register is set to the default value.
6	0b RW/P	**Selectable De-emphasis (SD):** When the Link is operating at 5.0 GT/s speed, this bit selects the level of de-emphasis for an Upstream component. Encodings: 1b -3.5 dB 0b -6 dB When the Link is operating at 2.5 GT/s speed, the setting of this bit has no effect.
5	0b RO	**Hardware Autonomous Speed Disable (HASD):** Reserved. This port cannot autonomously change speeds.
4	0b RW/P	**Enter Compliance (EC):** Software is permitted to force a Link to enter Compliance mode at the speed indicated in the Target Link Speed field by setting this bit to 1b in both components on a Link and then initiating a hot reset on the Link. Default value of this bit following Fundamental Reset is 0b.
3:0	0h RW/P	**Target Link Speed (TLS):** This field sets an upper limit on Link operational speed by restricting the values advertised by the upstream component in its training sequences. For root port, the allowed value is: 0001b 2.5 GT/s Target Link Speed 0010b 5.0 GT/s and 2.5GT/s Link speeds supported If a value is written to this field that does not correspond to a speed included in the Supported Link Speeds field, the result is undefined. The default value of this field is the highest Link speed supported by the component (as reported in the Supported Link Speeds field of the Link Capabilities register).

When clear, devices do perform an internal reset upon transitioning from D3hot to D0 via software control of the Power State bits. Configuration Context is lost when performing the soft reset. Upon transition from D3hot to D0 state, full reinitialization sequence is needed to return the device to D0 Initialized. Regardless of this bit, devices that transition from D3hot to D0 by a system or bus segment reset will return to the device state D0 Uninitialized with only PME context preserved if PME is supported and enabled.
2	0b RO	**Reserved (RSVD_2):** Reserved
1:0	00b RW	**Power State (PS):** This field is used both to determine the current power state of the root port and to set a new power state. The values are: 00 D0 state 11 D3HOT state When in the D3HOT state, the controller's configuration space is available, but the I/O and memory spaces are not. Type 1 configuration cycles are also not accepted. Interrupts are not required to be blocked as software will disable interrupts prior to placing the port into D3HOT. If software attempts to write a '10' or '01' to these bits, the write will be ignored.

Bit Range	Default & Access	Description
16	0b RO/V	**Data Link Layer Retry (DLLRETRY):** Indicates when the Data Link Layer has received a corrupted TLP or has detected a dropped packet and is currently waiting for the remote agent to re-transmit the corrupted/dropped packet. The value of Next Receive Sequence Number will be the sequence number associated with the corrupted packet.
15:12	0h RO/V	**Lane Status (LANESTAT):** Indicates which lanes are trained. A '1' indicates that the corresponding lane is trained (i.e. bit 0 = '1' means lane 0 is trained).

Bit Range	Default & Access	Description
31	0h RW	**cri_dfx_patbuftrain:** Pattern Buffer Manual Training When DFXPATBUFTRAINOVR and DFXLCESTART are asserted, this manually controls whether the Pattern Buffers are in training or have completed training. 0 : Send training patterns (default) 1 : Send contents of DFXPATBUF
30:28	0h RW	**cri_dfx_prbspoly_2_0:** PRBS Polynomial Select the polynomial to be used by the PRBS in the Pattern Generator and Pattern Checker. PRBS support 10b or 8b, which is indicated by the msb. 000 - x^16 + x^5 + x^4 + x^3 + 1 (USB3/PCIe Scrambler) (8b) 001 - x^16 + x^15 + x^13 + x^4 + 1 (SATA scrambler) (8b) 010 - x^31 + x^28 + 1 (8b) 011 - x^7 + x^6 + 1 (8b) 100 - x^15 + x^14 + 1 (10b) 101 - x^23 + x^18 + 1 (10b) 110 - x^31 + x^28 + 1 (10b) 111 - x^7 + x^6 + 1 (10b)
27:26	0h RW	**cri_dfx_patbufsize_1_0:** Pattern Buffer Size Select the size of the Pattern Buffer to use. The MSB will always be bit 79. The LSB will depend on this select and the DFXLCEDATAWIDTH (10b or 8b mode). 00 : full 80b buffer (Default) 01 : 70b (while in 10b mode), 56b (while in 8b mode) 10 : 40b (while in 10b mode), 32b (while in 8b mode) 11 : 10b (while in 10b mode), 8b (while in 8b mode)
25	0h RW	**cri_dfx_patbufloop:** Pattern Buffer Looping Enable Enables looping of the Patter Buffer. By default, the contents of Pattern Buffer will be used once and stop. Alternatively, the Pattern Buffer will continue to loop until the DFXLCESTART is de-asserted. 0 : Run Pattern Buffer only once (default) 1 : Loop Pattern Buffer until stopped
24	0h RW	**cri_dfx_patbufdwidth:** Pattern Buffer Data Width Selects between 10 bit or 8 bit data width for the Pattern Buffer. Determines where in the Tx/Rx path the data is inserted/retrieved. 0 : 10b (default) 1 : 8b
23	0h RW	**cri_dfx_patbuftrainovr:** Pattern Buffer Training Override Enables manual training of the Pattern Buffer instead of the automated coordination between the Pattern Checker and Patter Generator. When asserted, the DFXPATBUFTRAIN bit will be used to force when training is active and when it is complete. 0 : Automatic Training (default) 1 : Enable Manual Training
22	0h RW	**cri_dfx_marginmode:** Margin mode Overrides standard setup configurations for use with Eye Width Margining. 0 : Standard Mode (default) 1 : Margin Mode enabled
21	0h RW	**cri_dfx_chk_sel:** Pattern Checker 8b10b Select This determines where Rx data is compared, either in the 10-bit domain before decode or after 10b-)8b decoding. 0: 10b domain 1: 8b domain
20	0h RW	**cri_dfx_patchken:** Pattern Checker Enable 0 : Disable Pattern Checker (default) 1 : Enable Pattern Checker
19	0h RW	**cri_dfx_patgenen:** Pattern Generator Enable This will activate the DFx bypass muxes in the PCS Tx path. 0 : Disable Pattern Generator (default) 1 : Enable Pattern Generator
18	0h RW	**cri_dfx_clrerrcnt:** Clear Error Counter Resets the Pattern Checker's error counter. 0 : Error Counter allowed to run (default) 1 : Error Counter held in reset
17	0h RW	**cri_dfx_lcereset:** Local Compare Engine Reset Resets all components of the Local Compare Engine in both the Pattern Generator and the Pattern Checker. 0 : LCE not in reset (default) 1 : LCE in reset
16	0h RW	**cri_dfx_lcestart:** Local Compare Engine Start Controls the starting and stopping of the LCE. Allows for simultaneous or independent start across lanes. Once stopped, a DFXLCERESET is usually required. 0 : LCE stopped (default) 1 : LCE running
15:8	3Eh RW	**cri_dfx_patbuf_7_0:** Pattern Buffer Storage In 10b mode, the buffer is read as eight 10b chunks. The first 10 bits should not equal the Comma Symbol: '0011111010' (or its inversion '1100000101'). In 8b mode, the buffer is read as eight 10b chunks, where the 10th bit is unused and the 9th bit is the K-bit indicator. The first 10 bits should not equal the Comma Symbol: 'xx10111100'. DFXPATBUF[78] should not = '1'.

25	0h RW	**i_rxsq_asyncmode_h:** Squelch Async Startup Mode This squelch startup mode is power state independent. When enabled, the squelchen signal sent to Modphy will asynchronously enable the squelch detector circuit. Once enabled, the squelch detector circuit will asynchronously send an unfiltered/unqualified squelch indication signal out of Modphy. The squelch indication signal will initially be unstable, so it is up to the consumer of this signal to filter/qualfiy it accordingly. The asynchronous squelch startup mode is beneficial because it significantly reduces the squelch startup latency. This decrease in latency does come at the cost of slightly higher power when squelch is not enabled as the IREF and Squelch Keeper circuits must remain enabled. When disabled, the squelch startup sequence is synchronous in nature and the squelch indication signal sent out of Modphy is stable/filtered.

27:26	0h RW	**cri_dfx_patbufsize_1_0:** Pattern Buffer Size Select the size of the Pattern Buffer to use. The MSB will always be bit 79. The LSB will depend on this select and the DFXLCEDATAWIDTH (10b or 8b mode). 00 : full 80b buffer (Default) 01 : 70b (while in 10b mode), 56b (while in 8b mode) 10 : 40b (while in 10b mode), 32b (while in 8b mode) 11 : 10b (while in 10b mode), 8b (while in 8b mode)
25	0h RW	**cri_dfx_patbufloop:** Pattern Buffer Looping Enable Enables looping of the Patter Buffer. By default, the contents of Pattern Buffer will be used once and stop. Alternatively, the Pattern Buffer will continue to loop until the DFXLCESTART is de-asserted. 0 : Run Pattern Buffer only once (default) 1 : Loop Pattern Buffer until stopped
24	0h RW	**cri_dfx_patbufdwidth:** Pattern Buffer Data Width Selects between 10 bit or 8 bit data width for the Pattern Buffer. Determines where in the Tx/Rx path the data is inserted/retrieved. 0 : 10b (default) 1 : 8b
23	0h RW	**cri_dfx_patbuftrainovr:** Pattern Buffer Training Override Enables manual training of the Pattern Buffer instead of the automated coordination between the Pattern Checker and Patter Generator. When asserted, the DFXPATBUFTRAIN bit will be used to force when training is active and when it is complete. 0 : Automatic Training (default) 1 : Enable Manual Training
22	0h RW	**cri_dfx_marginmode:** Margin mode Overrides standard setup configurations for use with Eye Width Margining. 0 : Standard Mode (default) 1 : Margin Mode enabled
21	0h RW	**cri_dfx_chk_sel:** Pattern Checker 8b10b Select This determines where Rx data is compared, either in the 10-bit domain before decode or after 10b-)8b decoding. 0: 10b domain 1: 8b domain
20	0h RW	**cri_dfx_patchken:** Pattern Checker Enable 0 : Disable Pattern Checker (default) 1 : Enable Pattern Checker
19	0h RW	**cri_dfx_patgenen:** Pattern Generator Enable This will activate the DFx bypass muxes in the PCS Tx path. 0 : Disable Pattern Generator (default) 1 : Enable Pattern Generator
18	0h RW	**cri_dfx_clrerrcnt:** Clear Error Counter Resets the Pattern Checker's error counter. 0 : Error Counter allowed to run (default) 1 : Error Counter held in reset
17	0h RW	**cri_dfx_lcereset:** Local Compare Engine Reset Resets all components of the Local Compare Engine in both the Pattern Generator and the Pattern Checker. 0 : LCE not in reset (default) 1 : LCE in reset
16	0h RW	**cri_dfx_lcestart:** Local Compare Engine Start Controls the starting and stopping of the LCE. Allows for simultaneous or independent start across lanes. Once stopped, a DFXLCERESET is usually required. 0 : LCE stopped (default) 1 : LCE running
15:8	3Eh RW	**cri_dfx_patbuf_7_0:** Pattern Buffer Storage In 10b mode, the buffer is read as eight 10b chunks. The first 10 bits should not equal the Comma Symbol: '0011111010' (or its inversion '1100000101'). In 8b mode, the buffer is read as eight 10b chunks, where the 10th bit is unused and the 9th bit is the K-bit indicator. The first 10 bits should not equal the Comma Symbol: 'xx10111100'. DFXPATBUF[78] should not = '1'.

25	0h RW	**i_rxsq_asyncmode_h:** Squelch Async Startup Mode This squelch startup mode is power state independent. When enabled, the squelchen signal sent to Modphy will asynchronously enable the squelch detector circuit. Once enabled, the squelch detector circuit will asynchronously send an unfiltered/unqualified squelch indication signal out of Modphy. The squelch indication signal will initially be unstable, so it is up to the consumer of this signal to filter/qualfiy it accordingly. The asynchronous squelch startup mode is beneficial because it significantly reduces the squelch startup latency. This decrease in latency does come at the cost of slightly higher power when squelch is not enabled as the IREF and Squelch Keeper circuits must remain enabled. When disabled, the squelch startup sequence is synchronous in nature and the squelch indication signal sent out of Modphy is stable/filtered.

25	0h RW	**i_rxsq_asyncmode_h:** Squelch Async Startup Mode This squelch startup mode is power state independent. When enabled, the squelchen signal sent to Modphy will asynchronously enable the squelch detector circuit. Once enabled, the squelch detector circuit will asynchronously send an unfiltered/unqualified squelch indication signal out of Modphy. The squelch indication signal will initially be unstable, so it is up to the consumer of this signal to filter/qualfiy it accordingly. The asynchronous squelch startup mode is beneficial because it significantly reduces the squelch startup latency. This decrease in latency does come at the cost of slightly higher power when squelch is not enabled as the IREF and Squelch Keeper circuits must remain enabled. When disabled, the squelch startup sequence is synchronous in nature and the squelch indication signal sent out of Modphy is stable/filtered.

12	0h RW	**reg_rxidle:** Chicken bit to override i_rxidle from controller and keep Rx in P0 or P0s
11	0h RW	**cri_rxrawdata_sel:** When asserted bypass K-align, 10b/8b decoder and Elastic buffer
10	0h RW	**cri_dynkalign_eco3302703_mode:** Kalign Mode Override Value When cri_dynkalign_eco3302703_ovren is set, this value selects kalignmode 0 - use register bits cri_kalignmode[1:0] to select kalignmode 1 - select the 4 COM kalign mode'
9	0h RW	**cri_dynkalign_eco3302703_ovren:** Kalign Mode Override Enable Overrides kalign mode select pin, allowing config bit kalignmode_override_val to select kalignmode.
8	0h RW	**reg_rxpwrfsm_pibiasoff_ovrride:** When asserted selects reg_rxpwrfsm_pibiasoff_delay[3:0]
7	0h RW	**cri_reset_kalignlck:** When asserted resets Kalign lock indication and Kalign is performed again. The conditions when this would assert includes and is not restricted to any power management states (L0s, L1) or polling quiet states etc.
6	0h RW	**cri_ebptrrst:** Global broadcast to all lanes that the Elastic Buffer pointers should be reset. This is a pulse and will be generated when we need to reset the pointers because of collision or various other reasons.
5	0h RW	**cri_comdispfix:** Chicken bit to force disparity in dynamic K-align mode

Bit Range	Default & Access	Description
4	0h RW	**cri_forcebankhit:** Chicken bit to enable data appear on NOA post k-align lock although k-align block is not achieving lock. This is only for NOA observeability and not for other purpose
3:2	0h RW	**cri_kalignmode_1_0:** KALIGN Mode Select 00 = dynamic kalign all the time. Accounts for bit slips on incoming stream which can cause symbol to be detected on different bank 10 = dynamic kalign up to L0 x1 = static kalign (same as GDG). Assumes symbol always detected on same data bank
1	0h RW	**cri_skpprocdis:** SKIP Ordered-Set Processing Disable When this configuration bit is asserted, then SKIP ordered=sets will be ignored (in EB block). Used in Elastic buffer block. 0 = Normal operation. SKIP ordered=sets will be processed by the Elastic Buffer 1 = SKIP processing disabled.
0	0h RW	**cri_elasticbuffer_maskdis:** Config bit (chicken bit) to disable the masking logic after elec idle ordered set is seen

Bit Range	Default & Access	Description
31	0h RW	**cri_dfx_patbuftrain:** Pattern Buffer Manual Training When DFXPATBUFTRAINOVR and DFXLCESTART are asserted, this manually controls whether the Pattern Buffers are in training or have completed training. 0 : Send training patterns (default) 1 : Send contents of DFXPATBUF
30:28	0h RW	**cri_dfx_prbspoly_2_0:** PRBS Polynomial Select the polynomial to be used by the PRBS in the Pattern Generator and Pattern Checker. PRBS support 10b or 8b, which is indicated by the msb. 000 - x^16 + x^5 + x^4 + x^3 + 1 (USB3/PCIe Scrambler) (8b) 001 - x^16 + x^15 + x^13 + x^4 + 1 (SATA scrambler) (8b) 010 - x^31 + x^28 + 1 (8b) 011 - x^7 + x^6 + 1 (8b) 100 - x^15 + x^14 + 1 (10b) 101 - x^23 + x^18 + 1 (10b) 110 - x^31 + x^28 + 1 (10b) 111 - x^7 + x^6 + 1 (10b)
27:26	0h RW	**cri_dfx_patbufsize_1_0:** Pattern Buffer Size Select the size of the Pattern Buffer to use. The MSB will always be bit 79. The LSB will depend on this select and the DFXLCEDATAWIDTH (10b or 8b mode). 00 : full 80b buffer (Default) 01 : 70b (while in 10b mode), 56b (while in 8b mode) 10 : 40b (while in 10b mode), 32b (while in 8b mode) 11 : 10b (while in 10b mode), 8b (while in 8b mode)
25	0h RW	**cri_dfx_patbufloop:** Pattern Buffer Looping Enable Enables looping of the Patter Buffer. By default, the contents of Pattern Buffer will be used once and stop. Alternatively, the Pattern Buffer will continue to loop until the DFXLCESTART is de-asserted. 0 : Run Pattern Buffer only once (default) 1 : Loop Pattern Buffer until stopped
24	0h RW	**cri_dfx_patbufdwidth:** Pattern Buffer Data Width Selects between 10 bit or 8 bit data width for the Pattern Buffer. Determines where in the Tx/Rx path the data is inserted/retrieved. 0 : 10b (default) 1 : 8b
23	0h RW	**cri_dfx_patbuftrainovr:** Pattern Buffer Training Override Enables manual training of the Pattern Buffer instead of the automated coordination between the Pattern Checker and Patter Generator. When asserted, the DFXPATBUFTRAIN bit will be used to force when training is active and when it is complete. 0 : Automatic Training (default) 1 : Enable Manual Training
22	0h RW	**cri_dfx_marginmode:** Margin mode Overrides standard setup configurations for use with Eye Width Margining. 0 : Standard Mode (default) 1 : Margin Mode enabled
21	0h RW	**cri_dfx_chk_sel:** Pattern Checker 8b10b Select This determines where Rx data is compared, either in the 10-bit domain before decode or after 10b-)8b decoding. 0: 10b domain 1: 8b domain
20	0h RW	**cri_dfx_patchken:** Pattern Checker Enable 0 : Disable Pattern Checker (default) 1 : Enable Pattern Checker
19	0h RW	**cri_dfx_patgenen:** Pattern Generator Enable This will activate the DFx bypass muxes in the PCS Tx path. 0 : Disable Pattern Generator (default) 1 : Enable Pattern Generator
18	0h RW	**cri_dfx_clrerrcnt:** Clear Error Counter Resets the Pattern Checker's error counter. 0 : Error Counter allowed to run (default) 1 : Error Counter held in reset
17	0h RW	**cri_dfx_lcereset:** Local Compare Engine Reset Resets all components of the Local Compare Engine in both the Pattern Generator and the Pattern Checker. 0 : LCE not in reset (default) 1 : LCE in reset
16	0h RW	**cri_dfx_lcestart:** Local Compare Engine Start Controls the starting and stopping of the LCE. Allows for simultaneous or independent start across lanes. Once stopped, a DFXLCERESET is usually required. 0 : LCE stopped (default) 1 : LCE running
15:8	3Eh RW	**cri_dfx_patbuf_7_0:** Pattern Buffer Storage In 10b mode, the buffer is read as eight 10b chunks. The first 10 bits should not equal the Comma Symbol: '0011111010' (or its inversion '1100000101'). In 8b mode, the buffer is read as eight 10b chunks, where the 10th bit is unused and the 9th bit is the K-bit indicator. The first 10 bits should not equal the Comma Symbol: 'xx10111100'. DFXPATBUF[78] should not = '1'.

25	0h RW	**i_rxsq_asyncmode_h:** Squelch Async Startup Mode This squelch startup mode is power state independent. When enabled, the squelchen signal sent to Modphy will asynchronously enable the squelch detector circuit. Once enabled, the squelch detector circuit will asynchronously send an unfiltered/unqualified squelch indication signal out of Modphy. The squelch indication signal will initially be unstable, so it is up to the consumer of this signal to filter/qualfiy it accordingly. The asynchronous squelch startup mode is beneficial because it significantly reduces the squelch startup latency. This decrease in latency does come at the cost of slightly higher power when squelch is not enabled as the IREF and Squelch Keeper circuits must remain enabled. When disabled, the squelch startup sequence is synchronous in nature and the squelch indication signal sent out of Modphy is stable/filtered.

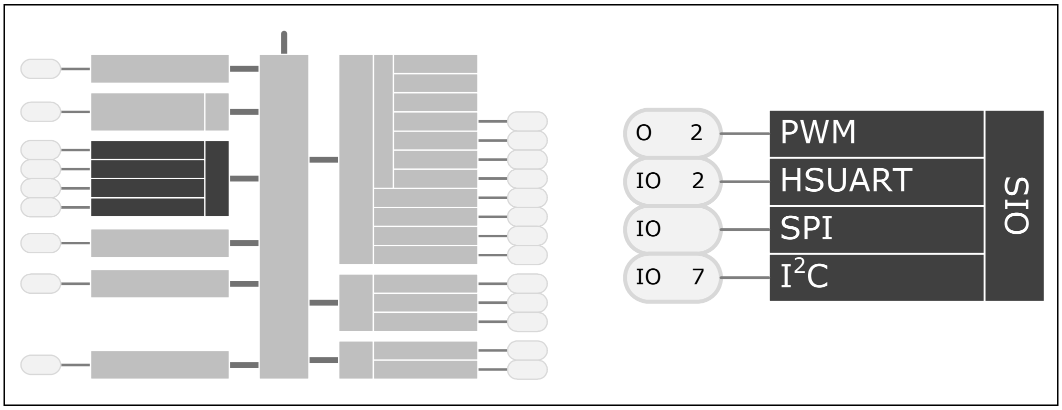
24 Serial IO (SIO) Overview

The Serial I/O (SIO) is a collection of hardware blocks that implement simple but key serial I/O interfaces for platform usage. These hardware blocks include:

- SIO - I²C Interface
- SIO – High Speed UART
- SIO - Serial Peripheral Interface (SPI)
- SIO – Pulse Width Modulation (PWM)



24.1 Serial I/O (SIO) Register Map

Refer to Chapter 3, “Register Access Methods” and Chapter 4, “Mapping Address Spaces” for additional information.

DEVICEID																VENDORID															

Bit Range	Default & Access	Field Name (ID): Description
31:16	0000h RO	**Device ID (DEVICEID):** Device ID identifies the particular AHB device. This is tied to a strap at the top level.
15:0	8086h RO	**Vendor ID (VENDORID):** Vendor ID is a unique ID provided by PCI SIG which identifies the manufacturer of the device. This is tied to a strap at the top level.

24.2.2 Status and Command (STATUSCOMMAND)—Offset 4h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:30, F:0] + 4h

Default: 00100000h

Reserved0	SSE	RMA	RTA	STA	Reserved1	CAPLIST	INTR_STATUS	Reserved2	Reserved3	INTR_DISABLE	Reserved4	SERR_ENABLE	Reserved5	BME	MSE	Reserved6

Bit Range	Default & Access	Field Name (ID): Description
31	0h RO	**Reserved0:** Reserved.
30	0h RW/1C	**SSE:** Reserved.
29	0h RW/1C	**Received Master Abort (RMA):** If the completion status received from IOSF is UR, Bridge sets this bit. S/W writes a 1. to this bit to clear it. This bit will not be set for the Fabric port. This bit is not used for the Fabric Port.
28	0h RW/1C	**Received Target Abort (RTA):** If the completion status received from IOSF is CA, Bridge sets this bit. S/W writes a 1.1 to this bit to clear it. This bit will not be set for the fabric port. This bit is not used for the Fabric Port.
27	0h RW/1C	**STA:** Reserved.
26:21	00h RO	**Reserved1:** Reserved.
20	1h RO	**Capabilities List (CAPLIST):** Hardwired to 1. Indicates that the controller contains a capabilities pointer list. The first item is pointed to by looking at configuration offset 34h. If PM capability is not required, then this bit should be tied to 0.
19	0h RO	**Interrupt Status (INTR_STATUS):** This bit reflects state of interrupt in the device. Only when the Interrupt Disable bit in the command register is a 0 and this Interrupt Status bit is a 1, will the device.s/function.s INTx# signal be asserted. Setting the Interrupt Disable bit to a 1 has no effect on the state of this bit. This bit reflects Legacy interrupt status.
18:16	0h RO	**Reserved2:** Reserved.
15:11	00h RO	**Reserved3:** Reserved.
10	0h RW	**Interrupt Disable (INTR_DISABLE):** Setting this bit disables INTx assertion from Bridge. The interrupt disabled is legacy INTx# interrupt, i.e. Bridge does not send Interrupt Assert message through the IOSF SideBand Channel.
9	0h RO	**Reserved4:** Reserved.
8	0h RW	**SERR# Enable (SERR_ENABLE):** If both SERR# Enable and the Unsupported Request Reporting Enable(URRE) register are 1., the agent sets the Signaled System Error bit in the PCI Status Register and sends an ERR_NONFATAL message on the IOSF sideband interface.

Bit Range	Default & Access	Field Name (ID): Description
7:3	00h RO	**Reserved5:** Reserved.
2	0h RW	**Bus Master Enable (BME):** If this bit is 0, Bridge does not generate any new upstream transaction on IOSF as a master.
1	0h RW	**Memory Space Enable (MSE):** This bit controls Bridge's response to downstream Memory accesses. When set, accesses to memory space of the device is enabled.
0	0h RO	**Reserved6:** Reserved.

24.2.3 Revision ID and Class Code (REVCLASSCODE)—Offset 8h

Access Method

Type: PCI Configuration Register (Size: 32 bits)

Offset: [B:0, D:30, F:0] + 8h

Default: 00000000h

31	28	24	20	16	12	8	4	0

CLASS_CODES	RID

Bit Range	Default & Access	Field Name (ID): Description
31:8	000000h RO	**Class Code (CLASS_CODES):** The Class Code register is read-only and used to identify the generic function of the device and, in some cases, a specific register level programming interface. The register is broken into three byte size fields. The upper byte (at offset 0Bh) is a base class code which broadly classifies the type of function the device performs. The middle byte (at offset 0Ah) is a sub-class code which identifies more specifically the function of the device. The lower byte (at offset 09h) identifies a specific register-level programming interface (if any) so that device independent software can interact with the device. This register is tied to a strap at the top level.
7:0	00h RO	**Revision ID (RID):** Revision ID identifies the revision of particular AHB device. This is tied to a strap at the top level.

24.2.4 Cache Line Latency Header and BIST (CLLATHEADERBIST)—Offset Ch

Access Method

Type: PCI Configuration Register (Size: 32 bits)

Offset: [B:0, D:30, F:0] + Ch

Default: 00800000h

Bits	31:24	23	22:16	15:8	7:0
Value	0 0 0 0 0 0 0 0	1	0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0
Field	Reserved0	MULFNDEV	HEADERTYPE	LATTIMER	CACHELINE_SIZE

Bit Range	Default & Access	Field Name (ID): Description
31:24	00h RO	**Reserved0:** Reserved.
23	1h RO	**Multi Function Device (MULFNDEV):** This bit is always 0 for non fabric ports. For Fabric ports it is driven from fabric_mult_function strap. • 1 = multifunction device • 0 = single function device
22:16	00h RO	**Header Type (HEADERTYPE):** Implements Type 0 Configuration header.
15:8	00h RO	**Latency Timer (LATTIMER):** Does not apply to PCI Express. Hardwired to 00h.
7:0	00h RW	**Cache Line Size (CACHELINE_SIZE):** Doesn't apply to PCI Express. PCI Express spec requires this to be implemented as a R/W register but has no functional impact on the AHB Device connected.

24.2.5 Base Address Register (BAR)—Offset 10h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:30, F:0] + 10h

Default: 00000000h

Bits	31:12	11:4	3	2:1	0
Value	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	0	0 0	0
Field	BASEADDR	SIZEINDICATOR	PREFETCHABLE	TYPE	MESSAGE_SPACE

Bit Range	Default & Access	Field Name (ID): Description
31:12	00000h RW	**Base Address (BASEADDR):** Base address of the AHB device memory space. Taken from Strap values as 1.s
11:4	00h RO	**Size Indicator Read Only (SIZEINDICATOR):** Always returns zero. The size of this register depends on the size of the Memory space. This size is determined by a top level of STRAP values as 0.s. Always will be zero as minimum size is 4K.
3	0h RO	**Prefetchable (PREFETCHABLE):** Indicates that this BAR is not prefetchable.

Bit Range	Default & Access	Field Name (ID): Description
2:1	0h RO	**Type (TYPE):** 00 indicates BAR lies in 32 bit address range.
0	0h RO	**Memory Space Indicator (MESSAGE_SPACE):** 0. Indicates this BAR is present in the memory space.

24.2.6 Base Address Register 1 (BAR1)—Offset 14h

Access Method

BASEADDR1																				SIZEINDICATOR1								PREFETCHABLE1	TYPE1		MESSAGE_SPACE1

Bit Range	Default & Access	Field Name (ID): Description
31:12	00000h RW	**Base Address Register 1 (BASEADDR1):** BAR1 of the LPIO device.
11:4	00h RO	**SIZEINDICATOR1:** Always will be zero as minimum size is 4K.
3	0h RO	**Prefetchable (PREFETCHABLE1):** Indicates that this BAR is not.
2:1	0h RO	**Type (TYPE1):** 00 Indicates BAR lies in 32 bit address range.
0	0h RO	**Memory Space Indicator (MESSAGE_SPACE1):** 0. Indicates this BAR is present in the memory space.

24.2.7 Subsystem Vendor and Subsystem ID (SUBSYSTEMID)—Offset 2Ch

Access Method

SUBSYSTEMID																SUBSYSTEMVENDORID															

Bit Range	Default & Access	Field Name (ID): Description
31:16	0000h RW/O	**Subsystem ID (SUBSYSTEMID):** This register should be implemented for any function that could be instantiated more than once in a given system. The SID register, in combination with the Subsystem Vendor ID register, make it possible for the operating environment to distinguish one audio subsystem from the other. This register is a Read Write Once type register.
15:0	0000h RW/O	**Subsystem Vendor ID (SUBSYSTEMVENDORID):** This register should be implemented for any function that could be instantiated more than once in a given system. The SVID register, in combination with the Subsystem ID register, enables the operating environment to distinguish one subsystem from the other. This register is a Read Write Once register.

24.2.8 Expansion ROM Base Address (EXPANSION_ROM_BASEADDR)—Offset 30h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:30, F:0] + 30h

Default: 00000000h

31			28				24				20				16				12				8				4				0

EXPANSION_ROM_BASE																															

Bit Range	Default & Access	Field Name (ID): Description
31:0	00000000h RO	**EXPANSION_ROM_BASE:** Reserved.

24.2.9 Capabilities Pointer (CAPABILITYPTR)—Offset 34h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:30, F:0] + 34h

Default: 00000000h

31			28				24				20				16				12				8				4				0
0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields: Reserved0 (31:8), CAPPTR_POWER (7:0)

Bit Range	Default & Access	Field Name (ID): Description
31:8	000000h RO	**Reserved0:** Reserved.
7:0	00h RO	**Capabilities Pointer (CAPPTR_POWER):** Indicates what the next capability is. This capability can be programmed to be PM Capability (0x80) if PM Capability is enabled in SB. If PM capability is disabled then this register has 00h.

24.2.10 Interrupt Register (INTERRUPTREG)—Offset 3Ch

Access Method

Type: PCI Configuration Register (Size: 32 bits) **Offset:** [B:0, D:30, F:0] + 3Ch

Default: 00000100h

31			28				24				20				16				12				8				4				0
0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0

Fields: MAX_LAT (31:24), MIN_GNT (23:16), Reserved0 (15:12), INTPIN (11:8), INTLINE (7:0)

Bit Range	Default & Access	Field Name (ID): Description
31:24	00h RO	**Max_Lat (MAX_LAT):** Value of 0 indicates device has no major requirements for the settings of latency timers.
23:16	00h RO	**Min_Gnt (MIN_GNT):** Value of 0 indicates device has no major requirements for the settings of latency timers.
15:12	0h RO	**Reserved0:** Reserved.
11:8	1h RO	**Interrupt Pin (INTPIN):** Each AHB IP on Bridge is a Single function device. Hence Bridge only generates INTA on IOSF SB. The Fabric on AHB Bridge appears as a Multifunction device. Interrupt Pin Value in this register is reflected from the IPIN value in the private configuration space.
7:0	00h RW	**Interrupt Line (INTLINE):** Bridge does not use this field directly. It is used to tell software which interrupt line the interrupt pin is connected to.

24.2.11 PowerManagement Capability ID (POWERCAPID)—Offset 80h

Access Method

Type: PCI Configuration Register (Size: 32 bits) **Offset:** [B:0, D:30, F:0] + 80h

Default: 00030001h

31	28	24	20	16	12	8	4	0
	0 0 0 0	0 0 0 0	0 0 0 0	0 0 1 1	0 0 0 0	0 0 0 0	0 0 0 0	0 0 0 1

PMESUPPORT	Reserved0	VERSION	NXTCAP	POWER_CAP

Bit Range	Default & Access	Field Name (ID): Description
31:27	00h RO	**PME_Support (PMESUPPORT):** This 5-bit field indicates the power states in which the function may assert PME#. A value of 0b for any bit indicates that the function is not capable of asserting the PME# signal while in that power state. • bit(11) X XXX1b - PME# can be asserted from D0. • bit(12) X XX1Xb - PME# can be asserted from D1. Bridge does not support this state. • bit(13) X X1XXb - PME# can be asserted from D2. Bridge does not support this state. • bit(14) X 1XXXb - PME# can be asserted from D3hot. • bit(15) 1 XXXXb - PME# can be asserted from D3cold. Bridge does not support this state. This field is taken from the strap strap_pme_support.
26:19	00h RO	**Reserved0:** Reserved.
18:16	3h RO	**Version (VERSION):** Indicates support for Revision 1.2 of the PCI Power Management Specification.
15:8	00h RO	**Next Capability (NXTCAP):** Points to the next capability structure. This points to NULL.
7:0	01h RO	**Power Management Capability (POWER_CAP):** Indicates this is power management capability.

24.2.12 PME Control and Status Register (PMECTRLSTATUS)—Offset 84h

Access Method

Type: PCI Configuration Register (Size: 32 bits)

Offset: [B:0, D:30, F:0] + 84h

Default: 00000008h

31	28	24	20	16	12	8	4	0
	0 0 0 0	0 0 0 0	0 0 0 0	0 0 0 0	0 0 0 0	0 0 0 0	0 0 0 0	1 0 0 0

Reserved0	PMESTATUS	Reserved1	PMEENABLE	Reserved2	NO_SOFT_RESET	Reserved3	POWERSTATE

Bit Range	Default & Access	Field Name (ID): Description
31:16	0000h RO	**Reserved0:** Reserved.

Bit Range	Default & Access	Field Name (ID): Description
15	0h RW/1C	**PME Status (PMESTATUS):** • 0 = Software clears the bit by writing a 1 to it. • 1 = This bit is set when the AHB Device would normally assert the PME# signal independent of the state of the PME Enable bit (bit 8 in this register).
14:9	00h RO	**Reserved1:** Reserved.
8	0h RW	**PME Enable (PMEENABLE):** A 1 enables the function to assert PME#. When 0, PME# message on SB is disabled.
7:4	0h RO	**Reserved2:** Reserved.
3	1h RO	**No_Soft_Reset (NO_SOFT_RESET):** This bit indicates that devices transitioning from D3hot to D0 because of PowerState commands do not perform an internal reset. Configuration Context is preserved.
2	0h RO	**Reserved3:** Reserved.
1:0	0h RW	**Power State (POWERSTATE):** This field is used both to determine the current power state of the AHB IP and to set a new power state. The values are: • 00 = D0 state • 11 = D3HOT state • Others = Reserved Notes: If software attempts to write a value of 01b or 10b in to this field, the write operation must complete normally; however, the data is discarded and no state change occurs. When in the D3HOT states, interrupts are blocked. D3Hot will not be used for Downstream decode on fabric ports.

24.2.13 Manufacturer ID (MANID)—Offset F8h

Access Method

Type: PCI Configuration Register (Size: 32 bits)

Offset: [B:0, D:30, F:0] + F8h

Default: 00000000h

31			28				24				20				16				12				8				4				0

31:15	0h RW	**Undefined:** Reserved.
14:11	0h RW	**DEST_PER:** Assigns a hardware handshaking interface (0 - DMAH_NUM_HS_INT-1) to the destination of channel x if the CFGx.HS_SEL_DST field is 0; otherwise, this field is ignored.
10:7	0h RW	**SRC_PER:** Assigns a hardware handshaking interface (0 - DMAH_NUM_HS_INT-1) to the source of channel x if the CFGx.HS_SEL_SRC field is 0; otherwise, this field is ignored.
6	0h RW	**Source Status Update Enable (SS_UPD_EN):** Source status information is fetched only from the location pointed to by the SSTATARx register, stored in the SSTATx register and written out to the SSTATx location of the LLI (refer to Figure 52 on page 243) if SS_UPD_EN is high.
5	0h RW	**Destination Status Update Enable (DS_UPD_EN):** Destination status information is fetched only from the location pointed to by the DSTATARx register, stored in the DSTATx register and written out to the DSTATx location of the LLI if DS_UPD_EN is high.
4:2	1h RW	**PROTCTL:** Protection Control bits used to drive the AHB HPROT[3:1] bus.
1	0h RW	**FIFO Mode Select (FIFO_MODE):** Determines how much space or data needs to be available in the FIFO before a burst transaction request is serviced. • 0 = Space/data available for single AHB transfer of the specified transfer width. • 1 = Data available is greater than or equal to half the FIFO depth for destination transfers and space available is greater than half the fifo depth for source transfers.
0	0h RW	**Flow Control Mode (FCMODE):** Determines when source transaction requests are serviced when the Destination Peripheral is the flow controller. • 0 = Source transaction requests are serviced when they occur. Data pre-fetching is enabled. • 1 = Source transaction requests are not serviced until a destination transaction request occurs.
