### 17.17.15 PCS\_DWORD14 (pcs\_dword14)—Offset 38h

#### Access Method

**Type:** Message Bus Register  
(Size: 32 bits)

**pcs\_dword14:** [Port: 0xA3] + (2200h + 38h)

#### Op Codes:

0h - Read, 1h - Write

Default: 007A0018h

| 25        | 0h<br>RW         | <b>i_rxsq_asyncmode_h:</b> Squelch Async Startup Mode This squelch startup mode is power state independent. When enabled, the squelchen signal sent to Modphy will asynchronously enable the squelch detector circuit. Once enabled, the squelch detector circuit will asynchronously send an unfiltered/unqualified squelch indication signal out of Modphy. The squelch indication signal will initially be unstable, so it is up to the consumer of this signal to filter/qualify it accordingly. The asynchronous squelch startup mode is beneficial because it significantly reduces the squelch startup latency. This decrease in latency does come at the cost of slightly higher power when squelch is not enabled as the IREF and Squelch Keeper circuits must remain enabled. When disabled, the squelch startup sequence is synchronous in nature and the squelch indication signal sent out of Modphy is stable/filtered. |

## 17.17.18 PCS\_DWORD17 (pcs\_dword17)—Offset 44h

### Access Method

**Type:** Message Bus Register  
(Size: 32 bits)

**pcs\_dword17:** [Port: 0xA3] + (2200h + 44h)

### Op Codes:

0h - Read, 1h - Write

**Default:** 01000001h

### 17.18.13 TX\_DWORD12 (tx\_dword12)—Offset 30h

#### Access Method

**Type:** Message Bus Register  
(Size: 32 bits)

**tx\_dword12:** [Port: 0xA6] + (280h + 30h)

#### Op Codes:

0h - Read, 1h - Write

**Default:** 00000000h

| 25        | 0h<br>RW         | <b>i_rxsq_asyncmode_h:</b> Squelch Async Startup Mode This squelch startup mode is power state independent. When enabled, the squelchen signal sent to Modphy will asynchronously enable the squelch detector circuit. Once enabled, the squelch detector circuit will asynchronously send an unfiltered/unqualified squelch indication signal out of Modphy. The squelch indication signal will initially be unstable, so it is up to the consumer of this signal to filter/qualify it accordingly. The asynchronous squelch startup mode is beneficial because it significantly reduces the squelch startup latency. This decrease in latency does come at the cost of slightly higher power when squelch is not enabled as the IREF and Squelch Keeper circuits must remain enabled. When disabled, the squelch startup sequence is synchronous in nature and the squelch indication signal sent out of Modphy is stable/filtered. |
| 24        | 1h<br>RW         | <b>i_rxsquelchstby_h:</b> Fast Squelch Enable Mode Bit to keep the IREF (ivrefen) on during P2 and reduce squelch startup time.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

### 17.20.13 TX\_DWORD12 (tx\_dword12)—Offset 30h

#### Access Method

**Type:** Message Bus Register  
(Size: 32 bits)

**tx\_dword12:** [Port: 0xA3] + (2480h + 30h)

#### Op Codes:

0h - Read, 1h - Write

**Default:** 00000000h

# 18 USB Host Controller Interfaces (xHCI, EHCI)

The USB Host Controllers (xHCI, EHCI) supports:

- One (1) Super Speed (SS) port on xHCI
- Four (4) Low Speed (LS)/Full Speed (FS)/High Speed (HS) ports on xHCI or EHCI
- Two (2) High Speed (HS) High Speed Inter-Chip (HSIC) ports on xHCI

**Note:** The SS port must share a LS/FS/HS port to have a full SS connector leaving three LS/FS/HS ports available.

**Note:** Only one host controller (either xHCI or EHCI) can be used. To enable HSIC and SS ports, xHCI must be used.

## 18.1 Signal Descriptions

See [Chapter 2, “Physical Interfaces”](#) for additional details.

The signal description table has the following headings:

- **Signal Name:** The name of the signal/pin
- **Direction:** The buffer direction can be either input, output, or I/O (bidirectional)
- **Platform Power:** The reference power plane.
- **Description:** A brief explanation of the signal’s function

Table 209. USB 3 SS Signals

| Signal Name   | Direction<br>Plat. Power | Description                                                                                                                                              |

**Figure 103.xHCI and EHCI Port Mapping**

**Note:** xHCI (3.0) SS is the debug port for xHCI controller.

**Note:** EHCI (1/2.0) Port 1 is the debug port of the EHCI controller

## 18.2 USB 3.0 xHCI (Extensible Host Controller Interface)

The xHCI compliant host controller can control up to 7 USB host ports. It supports devices conforming to USB 1.x to 3.0 at bit rates up to 5 Gbps.

### 18.2.1 Features of USB 3.0 Host

The USB 3.0 Super Speed data interface is a four wire differential (TX and RX pairs) interface that supports simultaneous bi-directional data transmission. The interface supports a bit rate of 5 Gbps with a maximum theoretical data throughput over 3.2 Gbps due to 8b/10b symbol encoding scheme and protocol overhead (link flow control, packet framing and protocol overhead).

Low Frequency Periodic signaling (LFPS) is used to communicate initialization, training and power management information across a link that is in low power link state without using Super Speed signaling. This reduces power consumption.

The USB3.0 port may be paired with any USB2 port at the connector – selection of any USB2 port other than port 0 will require the appropriate mapping. [Figure 103](#) shows the USB3 port paired with USB2 port 0.

#### USB3.0 Controller Features

- Supported by xHCI software host controller interface
- USB3 port disable
- Supports local dynamic clock gating and trunk clock gating
- Supports USB 3.0 LPM (U0, U1, U2, and U3) and also a SS Disabled low power state

- Support for USB3 Debug Device

**Note:** Recommended not to disconnect the connection when a debug session is in progress.

## **18.2.2 Features of USB HSIC**

HSIC is a 2-signal (strobe and data) source synchronous serial interface for on board inter-chip USB communication. The interface uses 240 MHz DDR signaling to provide High-Speed 480 Mb/s USB transfers which are 100% host driver compatible with traditional USB cable connected topologies. Full Speed (FS) and Low Speed (LS) USB transfers are not directly supported by the HSIC interface.

For details of HSIC applications supported, Contact local Intel Sales office.

Major feature and performance highlights are as follows:

- Supported by xHCI software host controller interface
- High-Speed 480 Mb/s data rate only
- Source-synchronous serial interface
- Interface Power is only consumed when a transfer is in progress
- No hot plug removal/attach at HSIC pins
- Signals driven at 1.2V standard LVCMOS levels
- Designed for low power applications
- Support for two host ports compliant to High Speed Inter-Chip Supplement (HSIC) to the USB 2.0 Specification. (USB 2.0)

## **18.3 USB 2.0 Enhanced Host Controller Interface (EHCI)**

The EHCI compliant host controller supports up to 4 USB 2.0 ports in legacy mode. USB 2.0 allows data transfers up to 480 Mbps. The controller integrates a Root Matching Hub (RMH) to support USB 1.1 devices.

**Note:** The EHCI is not used when the xHCI is used. The EHCI is primarily present for legacy usage, in cases when xHCI support is not available.

**Note:** Intel recommends using the xHCI controller for the USB2.0 ports irrespective of whether USB3.0 ports are implemented. The EHCI controller is provided for legacy OS/driver compatibility which is generally not required for tablet platforms. Using the xHCI controller will deliver significant power and performance benefits.

When following this recommendation on a platform with no USB3.0 support, the Windows logo requirement of USB debug port may not be met. Please consult with Intel regarding the impact of this.

**Note:** Unlike the xHCI, bandwidth of all four ports on the EHCI is shared across a single HS (480 Mbps) internal link.

### 18.3.1 Features of EHCI USB 2.0 Controller

The EHCI USB2.0 Controller supports the following features:

- Compliant with the specification for: USB 1.x, 2.0 (1.5 Mbps, 12 Mbps, 480 Mbps).
- 4 Ports shared with xHCI controller
- Enhanced EHCI descriptor caching
- All ports provided through USB Rate Matching Hubs (RMH) to support FS/LS devices
- Supports one Debug port at USB2 transfer rates
- Supports of USB suspend mode including PLL turn off in S0.
- Supports wakeup from suspend states S5 and remote-suspend wakeup
- All USB2 ports provide support for HS/FS/LS devices
- Per port USB disable
- Supports local dynamic clock gating and trunk clock gating
- Supports USB 2.0 LPM (L0, L1 and L2 low power states)

## 18.6 USB xHCI PCI Configuration Registers

**Table 212. Summary of USB xHCI PCI Configuration Registers—0/20/0**

| Offset | Size (Bytes) | Register Name (Register Symbol)                                                 | Default Value    |
|--------|--------------|---------------------------------------------------------------------------------|------------------|
| 0–1h   | 2            | "Vendor ID (VID)—Offset 0h" on page 2127                                        | 8086h            |
| 2–3h   | 2            | "Device ID (DID)—Offset 2h" on page 2128                                        | 8C31h            |
| 4–5h   | 2            | "Command (CMD)—Offset 4h" on page 2128                                          | 0000h            |
| 6–7h   | 2            | "Device Status (STS)—Offset 6h" on page 2129                                    | 0290h            |
| 8–8h   | 1            | "Revision ID (RID)—Offset 8h" on page 2131                                      | 00h              |
| 9–9h   | 1            | "Programming Interface (PI)—Offset 9h" on page 2131                             | 30h              |
| A–Ah   | 1            | "Sub Class Code (SCC)—Offset Ah" on page 2131                                   | 03h              |
| B–Bh   | 1            | "Base Class Code (BCC)—Offset Bh" on page 2132                                  | 0Ch              |
| D–Dh   | 1            | "Master Latency Timer (MLT)—Offset Dh" on page 2132                             | 00h              |
| E–Eh   | 1            | "Header Type (HT)—Offset Eh" on page 2132                                       | 00h              |
| 10–17h | 8            | "Memory Base Address (MBAR)—Offset 10h" on page 2133                            | 000000000000004h |
| 2C–2Dh | 2            | "USB Subsystem Vendor ID (SSVID)—Offset 2Ch" on page 2134                       | 0000h            |
| 2E–2Fh | 2            | "USB Subsystem ID (SSID)—Offset 2Eh" on page 2134                               | 0000h            |
| 34–34h | 1            | "Capabilities Pointer (CAP_PTR)—Offset 34h" on page 2135                        | 70h              |
| 3C–3Ch | 1            | "Interrupt Line (ILINE)—Offset 3Ch" on page 2135                                | 00h              |
| 3D–3Dh | 1            | "Interrupt Pin (IPIN)—Offset 3Dh" on page 2135                                  | 00h              |
| 40–43h | 4            | "XHC System Bus Configuration 1 (XHCC1)—Offset 40h" on page 2136                | 000000FDh        |
| 44–47h | 4            | "XHC System Bus Configuration 2 (XHCC2)—Offset 44h" on page 2137                | 0003C000h        |
| 50–53h | 4            | "Clock Gating (XHCLKGTEN)—Offset 50h" on page 2139                              | 00000120h        |
| 58–5Bh | 4            | "Audio Time Synchronization (AUDSYNC)—Offset 58h" on page 2142                  | 00000000h        |
| 60–60h | 1            | "Serial Bus Release Number (SBRN)—Offset 60h" on page 2143                      | 30h              |
| 61–61h | 1            | "Frame Length Adjustment (FLADJ)—Offset 61h" on page 2143                       | 20h              |
| 62–62h | 1            | "Best Effort Service Latency (BESL)—Offset 62h" on page 2144                    | 00h              |
| 70–70h | 1            | "PCI Power Management Capability ID (PM_CID)—Offset 70h" on page 2144           | 01h              |
| 71–71h | 1            | "Next Item Pointer #1 (PM_NEXT)—Offset 71h" on page 2145                        | 80h              |
| 72–73h | 2            | "Power Management Capabilities (PM_CAP)—Offset 72h" on page 2145                | C1C2h            |
| 74–75h | 2            | "Power Management Control/Status (PM_CS)—Offset 74h" on page 2146               | 0008h            |
| 80–80h | 1            | "Message Signaled Interrupt CID (MSI_CID)—Offset 80h" on page 2147              | 05h              |
| 81–81h | 1            | "Next item pointer (MSI_NEXT)—Offset 81h" on page 2148                          | 00h              |
| 82–83h | 2            | "Message Signaled Interrupt Message Control (MSI_MCTL)—Offset 82h" on page 2148 | 0086h            |
| 84–87h | 4            | "Message Signaled Interrupt Message Address (MSI_MAD)—Offset 84h" on page 2149  | 00000000h        |
| 88–8Bh | 4            | "Message Signaled Interrupt Upper Address (MSI_MUAD)—Offset 88h" on page 2149   | 00000000h        |

**Table 212. Summary of USB xHCI PCI Configuration Registers—0/20/0 (Continued)**

| Offset | Size (Bytes) | Register Name (Register Symbol)                                            | Default Value |
|--------|--------------|----------------------------------------------------------------------------|---------------|
| 8C–8Dh | 2            | "Message Signaled Interrupt Message Data (MSI_MD)—Offset 8Ch" on page 2150 | 0000h         |
| A0–A3h | 4            | "High Speed Configuration 1 (HSCFG1)—Offset A0h" on page 2150              | 00000100h     |
| A4–A7h | 4            | "High Speed Configuration 2 (HSCFG2)—Offset A4h" on page 2151              | 00002000h     |
| B0–B3h | 4            | "Super Speed Configuration 1 (SSCFG1)—Offset B0h" on page 2152             | 0000008Fh     |
| C0–C3h | 4            | "XHCI USB2 Overcurrent Pin Mapping 1 (U2OCM1)—Offset C0h" on page 2155     | 00000000h     |
| C4–C7h | 4            | "XHCI USB2 Overcurrent Pin Mapping 2 (U2OCM2)—Offset C4h" on page 2155     | 00000000h     |
| C8–CBh | 4            | "XHCI USB3 Overcurrent Pin Mapping 1 (U3OCM1)—Offset C8h" on page 2156     | 00000000h     |
| CC–CFh | 4            | "XHCI USB3 Overcurrent Pin Mapping 2 (U3OCM2)—Offset CCh" on page 2157     | 00000000h     |
| D0–D3h | 4            | "USB2 Port Routing (USB2PR)—Offset D0h" on page 2158                       | 00000000h     |
| D4–D7h | 4            | "USB2 Port Routing Mask (USB2PRM)—Offset D4h" on page 2159                 | 00000000h     |
| D8–DBh | 4            | "USB3 Port Routing (USB3PR)—Offset D8h" on page 2159                       | 00000000h     |
| DC–DFh | 4            | "USB3 Port Routing Mask (USB3PRM)—Offset DCh" on page 2160                 | 00000000h     |
| E0–E3h | 4            | "Fuse and Strap (FUS)—Offset E0h" on page 2160                             | 00000000h     |
| E4–E7h | 4            | "USB2 Port Disable Override (USB2PDO)—Offset E4h" on page 2162             | 00000000h     |
| E8–EBh | 4            | "USB3 Port Disable Override (USB3PDO)—Offset E8h" on page 2162             | 00000000h     |
| EC–EFh | 4            | "USB2 FS/LS Port Staggering Control (FSLSPS)—Offset ECh" on page 2163      | 0000D8D8h     |
| F0–F3h | 4            | "DFT 1 (DFT1)—Offset F0h" on page 2164                                     | 00000000h     |
| F4–F7h | 4            | "DFT 2 (DFT2)—Offset F4h" on page 2165                                     | 00000000h     |
| F8–FBh | 4            | "Manufacturing Process ID (MANID)—Offset F8h" on page 2166                 | 00000F00h     |
| FC–FFh | 4            | "DFT 3 (DFT3)—Offset FCh" on page 2167                                     | 00000000h     |

### 18.6.1 Vendor ID (VID)—Offset 0h

## Access Method

**Type:** PCI Configuration Register  
(Size: 16 bits)

**Offset:** [B:0, D:20, F:0] + 0h

**Default:** 8086h

|    |   |   |    |   |   |   |   |   |   |   |   |   |   |   |   |
|----|---|---|----|---|---|---|---|---|---|---|---|---|---|---|---|
| 15 |   |   | 12 |   |   |   | 8 |   |   |   | 4 |   |   |   | 0 |
| 1  | 0 | 0 | 0  | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 1 | 1 | 0 |
| WD |   |   |    |   |   |   |   |   |   |   |   |   |   |   |   |

| Bit Range | Default & Access | Field Name (ID): Description                                     |
|-----------|------------------|------------------------------------------------------------------|
| 15:0      | 8086h<br>RO      | <b>Vendor ID (VID):</b> Reserved.<br><br><b>Power Well:</b> Core |

## 18.6.2 Device ID (DID)—Offset 2h

### Access Method

**Type:** PCI Configuration Register  
(Size: 16 bits)

**Offset:** [B:0, D:20, F:0] + 2h

**Default:** 8C31h

|     |    |   |   |   |
|-----|----|---|---|---|
| 15  | 12 | 8 | 4 | 0 |
| 1   | 0  | 0 | 0 | 1 |
| 1   | 0  | 0 | 0 | 1 |
| DID |    |   |   |   |

| Bit Range | Default & Access | Field Name (ID): Description                                                                       |
|-----------|------------------|----------------------------------------------------------------------------------------------------|
| 15:0      | 8C31h<br>RO/V    | <b>Device ID (DID):</b> See Global Device ID table in Chap. 6 for value<br><b>Power Well:</b> Core |

## 18.6.3 Command (CMD)—Offset 4h

### Access Method

**Type:** PCI Configuration Register  
(Size: 16 bits)

**Offset:** [B:0, D:20, F:0] + 4h

**Default:** 0000h

|      |    |     |      |      |
|------|----|-----|------|------|
| 15   | 12 | 8   | 4    | 0    |
| 0    | 0  | 0   | 0    | 0    |
| RSVD | ID | FBE | SERR | WCC  |
|      |    | PER | VPS  | MWI  |
|      |    | SCE | BME  | MSE  |
|      |    |     |      | IOSE |

| Bit Range | Default & Access | Field Name (ID): Description                                                                                                                                                                                                                                                                              |

| 7:0       | 00h<br>RO        | <b>Master Latency Timer (MLT):</b> Because the XHC controller is internally implemented with arbitration on an internal interface, it does not need a master latency timer. The bits will be fixed at 0.<br><br><b>Power Well:</b> Core |

## 18.6.10 Header Type (HT)—Offset Eh

### Access Method

**Type:** PCI Configuration Register  
(Size: 8 bits)

**Offset:** [B:0, D:20, F:0] + Eh

**Default:** 00h

|     |    |   |
|-----|----|---|
| 7   | 4  | 0 |
| 0   | 0  | 0 |
| MFB | CL |   |

| Bit Range | Default & Access | Field Name (ID): Description                                                                                                 |
|-----------|------------------|------------------------------------------------------------------------------------------------------------------------------|
| 7         | 0b<br>RO         | <b>Multi-Function Bit (MFB):</b> Read only indicating single function device.<br><b>Power Well:</b> Core                     |
| 6:0       | 00h<br>RO        | <b>Configuration layout (CL):</b> Hardwired to 0 to indicate a standard PCI configuration layout.<br><b>Power Well:</b> Core |

### 18.6.11 Memory Base Address (MBAR)—Offset 10h

Value in this register will be different after the enumeration process.

#### Access Method

**Type:** PCI Configuration Register  
(Size: 64 bits)

**Offset:** [B:0, D:20, F:0] + 10h

**Default:** 0000000000000004h

|    |   |   |   |   |   |   |   |   |   |   |   |      |   |   |              |      |

### 18.6.19 Clock Gating (XHCLKGTEN)—Offset 50h

#### Access Method

**Type:** PCI Configuration Register  
(Size: 32 bits)

**Offset:** [B:0, D:20, F:0] + 50h

**Default:** 00000120h

## 18.6.20 Audio Time Synchronization (AUDSYNC)—Offset 58h

This 32 bit register is used for audio stream synchronization across different devices. Global signal sample\_now captures a value in AUDSYNC register.

### Access Method

**Type:** PCI Configuration Register  
(Size: 32 bits)

**Offset:** [B:0, D:20, F:0] + 58h

**Default:** 00000000h

|       |      |    |    |    |       |      |   |   |

| 7:0       | 30h<br>RO        | <b>Serial Bus Release Number (SBRN):</b> A value of 30h indicates that this controller follows USB release 3.0.<br><b>Power Well:</b> SUS |

### 18.6.22 Frame Length Adjustment (FLADJ)—Offset 61h

This feature is used to adjust any offset from the clock source that generates the clock that drives the SOF counter. When a new value is written into these six bits, the length of the frame is adjusted. Its initial programmed value is system dependent based on the accuracy of hardware USB clock and is initialized by system BIOS. This register should only be modified when the HChalted bit in the USBSTS register is a one. Changing value of this register while the host controller is operating yields undefined results.

#### Access Method

**Type:** PCI Configuration Register  
(Size: 8 bits)

**Offset:** [B:0, D:20, F:0] + 61h

**Default:** 20h

| 7         | 0                | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 1 | 0    | 0 | 0 | 0 |

| Bit Range | Default & Access | Field Name (ID): Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0       | 80h<br>RW/L      | <b>Next Item Pointer #1 (PM_NEXT):</b> This register defaults to 80h, which indicates that the next capability registers begin at configuration offset 80h. This register is writable when the Access Control bit is set to '0'. This allows BIOS to effectively hide the next capability registers, if necessary. This register should only be written during system initialization before the plug-and-play software has enabled any master-initiated traffic. Values of: 80h implies next capability is MSI 00h implies that MSI capability is hidden. Note: This value is never expected to be programmed.<br><br><b>Power Well:</b> Core |

### 18.6.26 Power Management Capabilities (PM\_CAP)—Offset 72h

Normally, this register is read-only to report capabilities to the power management software. In order to report different power management capabilities depending on the system in which the Intel PCH is used, the write access to this register is controlled by the Access Control bit (ACCTRL). The value written to this register does not affect the hardware other than changing the value returned during a read. This register is modified and maintained by BIOS

#### Access Method

|-----------|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:0      | 0000h<br>RW      | <b>Data:</b> This 16-bit field is programmed by system software if MSI is enabled. Its content is driven onto the lower word (PCI AD(15:0)) during the data phase of the MSI memory write transaction. The Multiple Message Enable field (bits 6-4 of the Message Control register) defines the number of low order message data bits the function is permitted to modify to generate its system software allocated vectors. For example, a Multiple Message Enable encoding of 010 indicates the function has been allocated four vectors and is permitted to modify message data bits 1 and 0 (a function modifies the lower message data bits to generate the allocated number of vectors). If the Multiple Message Enable field is 000, the function is not permitted to modify the message data.<br><br><b>Power Well:</b> Core |

### 18.6.34 High Speed Configuration 1 (HSCFG1)—Offset A0h

Not for EDS

#### Access Method

**Type:** PCI Configuration Register  
(Size: 32 bits)

**Offset:** [B:0, D:20, F:0] + A0h

**Default:** 00000100h

Intel Atom® Processor E3800 Product Family  
Datasheet  
2151

#### 18.6.40 XHCI USB3 Overcurrent Pin Mapping 2 (U3OCM2)—Offset CCh

The RW/L property of this register is controlled by OCCFDONE bit. Note: U3OCM2 allows the OC pins 8:5 to be mapped to the same 6 SS ports that U3OCM1 allows. This allows flexibility in pairing SS ports with HS ports at the connector. Care must be taken to make sure OC pin assignment is consistent across USB3 and USB2 ports (depending upon the pairing).

##### Access Method

**Type:** PCI Configuration Register  
(Size: 32 bits)

**Offset:** [B:0, D:20, F:0] + CCh

## 18.6.52 DFT 3 (DFT3)—Offset FCh

Not for EDS

### Access Method

**Type:** PCI Configuration Register  
(Size: 32 bits)

**Offset:** [B:0, D:20, F:0] + FCh

**Default:** 00000000h

|                 |                 |                 |                 |                 |                 |                 |                 |                 |

### 18.7.1 Capability Registers Length (CAPLENGTH)—Offset 0h

This register is used as an offset to add to register base, to find the beginning of the Operational Register Space. This register is modified and maintained by BIOS.

#### Access Method

**Type:** Memory Mapped I/O Register  
(Size: 8 bits)

**Offset:** [MBAR] + 0h

**MBAR Type:** PCI Configuration Register (Size: 64 bits)

**MBAR Reference:** [B:0, D:20, F:0] + 10h

**Default:** 80h

|           |   |   |
|-----------|---|---|
| 7         | 4 | 0 |
| 1         | 0 | 0 |
| CAPLENGTH |   |   |

### 18.7.2 Host Controller Interface Version Number (HCIVERSION)—Offset 2h

This is a two-byte register containing a BCD encoding of the xHCI specification revision number supported by this host controller. The most significant byte of this register represents a major revision, and the least significant bit is the minor revision, e.g. 0100h corresponds to xHCI version 1.0. This register is modified and maintained by BIOS.

#### Access Method

**Type:** Memory Mapped I/O Register  
(Size: 16 bits)

**Offset:** [MBAR] + 2h

**MBAR Type:** PCI Configuration Register (Size: 64 bits)

**MBAR Reference:** [B:0, D:20, F:0] + 10h

| 2         | 0b<br>RW         | <p><b>Interrupter Enable (INTE):</b> This bit provides system software with a means of enabling or disabling the host system interrupts generated by Interrupters. When this bit is a 1, then Interrupter host system interrupt generation is allowed, i.e. the xHC shall issue an interrupt at the next interrupt threshold if the host system interrupt mechanism (e.g. MSI, MSIX, etc.) is enabled. The interrupt is acknowledged by a host system interrupt specific mechanism.</p> <p>When this register is exposed by a Virtual Function (VF), this bit only enables the set of Interrupters assigned to the selected VF.</p> <p><b>Power Well:</b> Core</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 1         | 0b<br>RW         | <p><b>Host Controller Reset (HCRST):</b> This control bit is used by software to reset the host controller. The effects of this bit on the xHC and the Root Hub registers are similar to a Chip Hardware Reset.</p> <p>When software writes a 1 to this bit, the Host Controller resets its internal pipelines, timers, counters, state machines, etc. to their initial value. Any transaction currently in progress on the USB is immediately terminated. A USB reset shall not be driven on USB2 downstream ports, however a Hot or Warm Reset shall be initiated on USB3 Root Hub downstream ports. PCI Configuration registers are not affected by this reset. All operational registers, including port registers and port state machines are set to their initial values. Software shall reinitialize the host controller, as described in the xHCI for USB specification, in order to return the host controller to an operational state.</p> <p>This bit is cleared to 0 by the Host Controller when the reset process is complete. Software cannot terminate the reset process early by writing a 0 to this bit and shall not write any xHC Operational or Runtime registers until while HCRST is 1. Note, the completion of the xHC reset process is not gated by the Root Hub port reset process. Software shall not set this bit to 1 when the HCHalted (HCH) bit in the USBSTS register is a 0. Attempting to reset an actively running host controller may result in undefined behavior. When this register is exposed by a Virtual Function (VF), this bit only resets the xHC instance presented by the selected VF. Refer to the xHCI for USB specification for more information.</p> <p><b>Power Well:</b> Core</p> |
| 0         | 0b<br>RW         | <p><b>Run/Stop (RS):</b></p> <ul style="list-style-type: none"> <li>1 = Run</li> <li>0 = Stop</li> </ul> <p>When set to a 1, the xHC proceeds with execution of the schedule. The xHC continues execution as long as this bit is set to a 1. When this bit is cleared to 0, the xHC completes any current or queued commands or TDs, and any USB transactions associated with them, then halts. Refer to section 5.4.1.1 for more information on how R/S shall be managed. The xHC shall halt within 16 ms. after software clears the Run/Stop bit if the above conditions have been met. The HCHalted (HCH) bit in the USBSTS register indicates when the xHC has finished its pending pipelined transactions and has entered the stopped state. Software shall not write a 1 to this flag unless the xHC is in the Halted state (i.e. HCH in the USBSTS register is 1). Doing so may yield undefined results. Writing a 0 to this flag when the xHC is in the Running state (i.e. HCH = 0) and any Event Rings are in the Event Ring Full state (refer to section 4.9.4) may yield undefined results. When this register is exposed by a Virtual Function (VF), this bit only controls the run state of the xHC instance presented by the selected VF.</p> <p><b>Power Well:</b> Core</p>                                                                                                                                                                                                                                                                                                                                                                                                                                           |

### 18.7.10 USB Status (USBSTS)—Offset 84h

This register indicates pending interrupts and various states of the Host Controller. The status resulting from a transaction on the serial bus is not indicated in this register. Software sets a bit to '0' in this register by writing a '1' to it (RW1C). Refer to specification *eXtensible Host Controller Interface for Universal Serial Bus (xHCI)* for additional information concerning USB interrupt conditions.

#### Access Method

**Type:** Memory Mapped I/O Register  
(Size: 32 bits)

**Offset:** [MBAR] + 84h

**MBAR Type:** PCI Configuration Register (Size: 64 bits)

**MBAR Reference:** [B:0, D:20, F:0] + 10h

**Default:** 00000001h

| Bit Range | Default & Access | Field Name (ID): Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4         | 0b<br>RW/C       | <p><b>Port Change Detect (PCD):</b> The xHC sets this bit to a 1 when any port has a change bit transition from a 0 to a 1. This bit is allowed to be maintained in the Aux Power well. Alternatively, it is also acceptable that on a D3 to D0 transition of the xHC, this bit is loaded with the OR of all of the PORTSC change bits. Refer to the xHCI for USB specification for more information. This bit provides system software an efficient means of determining if there has been Root Hub port activity. Refer to the xHCI for USB specification for more information. When this register is exposed by a Virtual Function (VF), the VMM determines the state of this bit as a function of the Root Hub Ports associated with the Device Slots assigned to the selected VF. Refer to the xHCI for USB specification for more information.</p> <p><b>Power Well:</b> Core</p>                                            |
| 3         | 0b<br>RW/C       | <p><b>Event Interrupt (EINT):</b> The xHC sets this bit to 1 when the <i>Interrupt Pending</i> (IP) bit of any Interrupter transitions from 0 to 1. Refer to the xHCI for USB specification for usage information. Software that uses <i>EINT</i> shall clear it prior to clearing any IP flags. A race condition may occur if software clears the <i>IP</i> flags, then clears the <i>EINT</i> flag, and between the operations another <i>IP</i> 0 to '1' transition occurs. In this case, the new IP transition shall be lost. When this register is exposed by a Virtual Function (VF), this bit is the logical 'OR' of the IP bits for the Interrupters assigned to the selected VF. And it shall be cleared to 0 when all associated interrupter IP bits are cleared, i.e. all the VFs Interrupter Event Ring(s) are empty. Refer to the xHCI for USB specification for more information.</p> <p><b>Power Well:</b> Core</p> |
| 2         | 0b<br>RW/C       | <p><b>Host System Error (HSE):</b> The xHC sets this bit to 1 when a serious error is detected, either internal to the xHC or during a host system access involving the xHC module. (In a PCI system, conditions that set this bit to 1 include PCI Parity error, PCI Master Abort, and PCI Target Abort.) When this error occurs, the xHC clears the Run/Stop (R/S) bit in the USBCMD register to prevent further execution of the scheduled TDs. If the HSEE bit in the USBCMD register is a 1, the xHC shall also assert out-of-band error signaling to the host. Refer to the xHCI for USB specification for more information. When this register is exposed by a Virtual Function (VF), the assertion of this bit affects all VFs and reflects the Host System Error state of the Physical Function (PF0). Refer to the xHCI for USB specification for more information.</p> <p><b>Power Well:</b> Core</p>                   |
| 1         | 0b<br>RO         | <p><b>Rsvd1:</b> Reserved.</p> <p><b>Power Well:</b> Core</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 0         | 1b<br>RO         | <p><b>HCHalted (HCH):</b> This bit is a 0 whenever the <i>Run/Stop</i> (R/S) bit is a 1. The xHC sets this bit to 1 after it has stopped executing as a result of the <i>Run/Stop</i> (R/S) bit being cleared to 0, either by software or by the xHC hardware (e.g. internal error). If this bit is '1', then SOFs, microSOFs, or Isochronous Timestamp Packets (ITP) shall not be generated by the xHC, and any received Transaction Packet shall be dropped. When this register is exposed by a Virtual Function (VF), this bit only reflects the Halted state of the xHC instance presented by the selected VF. Refer to the xHCI for USB specification for more information.</p> <p><b>Power Well:</b> Core</p>                                                                                                                                                                                                                |

### 18.7.11 Page Size (PAGESIZE)—Offset 88h

The default value for this register is implementation dependent.

| 15:0      | 0001h<br>RO      | <b>Page Size (PAGESIZE):</b> This field defines the page size supported by the xHC implementation. This xHC supports a page size of $2^{(n+12)}$ if bit n is Set. For example, if bit 0 is Set, the xHC supports 4k byte page sizes.<br>For a Virtual Function, this register reflects the page size selected in the <i>System Page Size</i> field of the SR-IOV Extended Capability structure. For the Physical Function 0, this register reflects the implementation dependent default xHC page size.<br>Various xHC resources reference PAGESIZE to describe their minimum alignment requirements. The maximum possible page size is 128M.<br><b>Power Well:</b> Core |

### 18.7.12 Device Notification Control (DNCTRL)—Offset 94h

This register is used by software to enable or disable the reporting of the reception of specific USB Device Notification Transaction Packets. A *Notification Enable* (Nx, where x = 0 to 15) flag is defined for each of the 16 possible device notification types. If a flag is set for a specific notification type, a Device Notification Event shall be generated when the respective notification packet is received. After reset, all notifications are disabled. Refer to specification *eXtensible Host Controller Interface for Universal Serial Bus (xHCI)*. This register shall be written as a Dword. Byte writes produce undefined results.

#### Access Method

| 2         | 0b<br>RW/S       | <p><b>Command Abort (CA):</b> Writing a '1' to this bit shall immediately terminate the currently executing command, stop the Command Ring, and generate a Command Completion Event with the Completion Code set to Command Ring Stopped. Refer to the xHCI for USB specification for more information on aborting a command. The next write to the <i>Host Controller Doorbell</i> with <i>DB Reason</i> field set to <i>Host Controller Command</i> shall restart the Command Ring operation. Writes to this flag are ignored by the xHC if <i>Command Ring Running</i> (CCR) = '0'. Reading this bit always returns '0'.</p> <p><b>Power Well:</b> Core</p>                                                                                                                                                                                                                                        |
| 1         | 0b<br>RW/S       | <p><b>Command Stop (CS):</b> Writing a '1' to this bit shall stop the operation of the Command Ring after the completion of the currently executing command, and generate a <i>Command Completion Event</i> with the <i>Completion Code</i> set to <i>Command Ring Stopped</i> and the <i>Command TRB Pointer</i> set to the current value of the <i>Command Ring Dequeue Pointer</i>. Refer to the xHCI for USB specification for more information on stopping a command. The next write to the <i>Host Controller Doorbell</i> with <i>DB Reason</i> field set to <i>Host Controller Command</i> shall restart the Command Ring operation. Writes to this flag are ignored by the xHC if <i>Command Ring Running</i> (CCR) = '0'. Reading this bit shall always return '0'.</p> <p><b>Power Well:</b> Core</p>                                                                                      |
| 0         | 0b<br>RW         | <p><b>Ring Cycle State (RCS):</b> This bit identifies the value of the xHC <i>Consumer Cycle State</i> (CCS) flag for the TRB referenced by the <i>Command Ring Pointer</i>. Refer to the xHCI for USB specification for more information. Writes to this flag are ignored if <i>Command Ring Running</i> is '1'. If the CRCR is written while the Command Ring is stopped (CCR = '0'), then the value of this flag shall be used to fetch the first Command TRB the next time the <i>Host Controller Doorbell</i> register is written with the <i>DB Reason</i> field set to <i>Host Controller Command</i>. If the CRCR is <i>not</i> written while the Command Ring is stopped (CCR = '0'), then the Command Ring shall begin fetching Command TRBs using the current value of the <i>Internal Command Ring CCS</i> flag. Reading this flag always returns '0'.</p> <p><b>Power Well:</b> Core</p> |

### 18.7.14 Command Ring High (CRCR\_HI)—Offset 9Ch

The Command Ring Control Register provides Command Ring control and status capabilities, and identifies the address and Cycle bit state of the Command Ring Dequeue Pointer.

#### Access Method

**Type:** Memory Mapped I/O Register  
(Size: 32 bits)

**Offset:** [MBAR] + 9Ch

**MBAR Type:** PCI Configuration Register (Size: 64 bits)

**MBAR Reference:** [B:0, D:20, F:0] + 10h

**Default:** 00000000h

### 18.7.19 Port 1 Power Management Status and Control USB2 (PORTPMSC1USB2)—Offset 484h

This register is in the Aux Power well. It is only reset by platform hardware during a cold reset or in response to a *Host Controller Reset* (HCRST). The USB2 Port Power Management Status and Control register provides the USB2 LPM parameters necessary for the xHC to generate a LPM Token to the downstream device.

#### Access Method

**Type:** Memory Mapped I/O Register  
(Size: 32 bits)

**Offset:** [MBAR] + 484h

**MBAR Type:** PCI Configuration Register (Size: 64 bits)

**MBAR Reference:** [B:0, D:20, F:0] + 10h

**Default:** 00000000h

For more information about <i>BESL</i> value encoding, refer to the xHCI for USB specification. Note that the <i>BESL</i> field is used by both software and hardware controlled LPM. Refer to the xHCI for USB specification for more information on <i>BESL</i> use and how <i>DBESL</i> may be used to establish an initial value for <i>BESL</i> .<br><b>Power Well:</b> SUS |
| 3         | 0b<br>RW         | <b>Remote Wake Enable (RWE):</b> Note: This register is sticky. System software sets this flag to enable or disable the device for remote wake from L1. The value of this flag shall temporarily (while in L1) override the current setting of the Remote Wake feature set by the standard Set/ClearFeature() commands defined in Universal Serial Bus Specification, revision 2.0, Chapter 9.<br><b>Power Well:</b> SUS                                                                                                                                                                                     |

There are 9 PorthLPM registers at offsets 48Ch, 49Ch, 4ACh, 4BCh, 4CCh, 4DCh, 4ECh, 4FCh and 50Ch. This register is reset only by platform hardware during cold reset or in response to a Host Controller Reset (HCRST). The field definitions depend on the protocol supported. For USB3, this register is reserved and shall be treated by software as RsvdP. For USB2, the definition is given below. Fields contain parameters necessary for xHC to automatically generate an LPM Token to the downstream device.

**Type:** Memory Mapped I/O Register  
(Size: 32 bits)

**MBAR Type:** PCI Configuration Register (Size: 64 bits)

**Default:** 00000000h

## 18.7.26 Port X Hardware LPM Control Register (PORTHLPM3)—Offset 4ACh

There are 9 PORTHLPM registers at offsets 48Ch, 49Ch, 4ACh, 4BCh, 4CCh, 4DCh, 4ECh, 4FCh and 50Ch. This register is reset only by platform hardware during cold reset or in response to a Host Controller Reset (HCRST). The field definitions depend on the protocol supported. For USB3, this register is reserved and shall be treated by software as RsvdP. For USB2, the definition is given below. Fields contain parameters necessary for xHC to automatically generate an LPM Token to the downstream device.

### Access Method

**Type:** Memory Mapped I/O Register  
(Size: 32 bits)

**Offset:** [MBAR] + 4ACh

**MBAR Type:** PCI Configuration Register (Size: 64 bits)

**MBAR Reference:** [B:0, D:20, F:0] + 10h

**Default:** 00000000h

### 18.7.39 Microframe Index (MFINDEX)—Offset 2000h

This register is used by the system software to determine the current periodic frame. The register value is incremented every 125 microseconds (once each microframe). This register is only incremented while *Run/Stop* = '1'. The value of this register affects the SOF value generated by USB2 Bus Instances.

## Access Method

**Type:** Memory Mapped I/O Register  
(Size: 32 bits)

**Offset:** [MBAR] + 2000h

**MBAR Type:** PCI Configuration Register (Size: 64 bits)

**MBAR Reference:** [B:0, D:20, F:0] + 10h

**Default:** 00000000h

#### 18.7.40 Interrupter 1 Management (IMAN1)—Offset 2020h

The Interrupter Management registers allow system software to enable, disable, detect and force xHC interrupts. There are 8 IMAN registers. x = 1, 2, ... 8.

## Access Method

**Type:** Memory Mapped I/O Register  
(Size: 32 bits)

**Offset:** [MBAR] + 2020h

**MBAR Type:** PCI Configuration Register (Size: 64 bits)

**MBAR Reference:** [B:0, D:20, F:0] + 10h

**Default:** 00000000h

|       |    |    |    |    |    |   |   |   |    |    |
|-------|----|----|----|----|----|---|---|---|----|----|
| 31    | 28 | 24 | 20 | 16 | 12 | 8 | 4 | 0 |    |    |

### 18.7.41 Interrupter 1 Moderation (IMOD1)—Offset 2024h

The Interrupter Moderation Register controls the 'interrupt moderation' feature of an interrupter, allowing system software to throttle the interrupt rate generated by the xHC. There are 8 IMOD registers. x = 1, 2, ... 8.

#### Access Method

**Type:** Memory Mapped I/O Register  
(Size: 32 bits)

**Offset:** [MBAR] + 2024h

**MBAR Type:** PCI Configuration Register (Size: 64 bits)

**MBAR Reference:** [B:0, D:20, F:0] + 10h

**Default:** 00000FA0h

| 15:0      | 0000h<br>RW      | <b>Event Ring Segment Table Size (ERSTS):</b> This field identifies the number of valid Event Ring Segment Table entries in the Event Ring Segment Table pointed to by the Event Ring Segment Table Base Address register. The maximum value supported by an xHC implementation for this register is defined by the ERST Max field in the HCSPARAMS2 register (see specification xHCI for USB).<br>For Secondary Interrupters: Writing a value of 0 to this field disables the Event Ring. Any events targeted at this Event Ring when it is disabled shall result in undefined behavior of the Event Ring.<br>For the Primary Interrupter: Writing a value of 0 to this field shall result in undefined behavior of the Event Ring. The Primary Event Ring cannot be disabled.<br><b>Power Well:</b> Core |

### 18.7.43 Event Ring Segment Table Base Address Low 1 (ERSTBA\_LO1)—Offset 2030h

The *Event Ring Segment Table Base Address Register* identifies the start address of the Event Ring Segment Table. There are 8 ERSTBA\_LOx registers, with x = 1, 2, ... 8.

#### Access Method

**Type:** Memory Mapped I/O Register  
(Size: 32 bits)

**Offset:** [MBAR] + 2030h

**MBAR Type:** PCI Configuration Register (Size: 64 bits)

**MBAR Reference:** [B:0, D:20, F:0] + 10h

**Default:** 00000000h

## 18.7.48 Interrupter 2 Moderation (IMOD2)—Offset 2044h

The Interrupter Moderation Register controls the 'interrupt moderation' feature of an interrupter, allowing system software to throttle the interrupt rate generated by the xHC. There are 8 IMOD registers. x = 1, 2, ... 8.

### Access Method

**Type:** Memory Mapped I/O Register  
(Size: 32 bits)

**Offset:** [MBAR] + 2044h

**MBAR Type:** PCI Configuration Register (Size: 64 bits)

**MBAR Reference:** [B:0, D:20, F:0] + 10h

**Default:** 00000FA0h

A value of '0' disables interrupt throttling logic, and interrupts shall be generated immediately if IP = '0', EHB = '0', and the Event Ring is not empty.<br><br><b>Power Well:</b> Core |

### 18.7.91 Event Ring Segment Table Size 8 (ERSTS8)—Offset 2108h

The *Event Ring Segment Table Size Register* defines the number of segments supported by the Event Ring Segment Table. There are 8 ERSTS registers. x = 1, 2, ... 8.

#### Access Method

**Type:** Memory Mapped I/O Register  
(Size: 32 bits)

**Offset:** [MBAR] + 2108h

**MBAR Type:** PCI Configuration Register (Size: 64 bits)

**MBAR Reference:** [B:0, D:20, F:0] + 10h

**Default:** 00000000h

### 18.7.151 Super Speed Bandwidth Overload (HOST\_BW\_OV\_SS\_REG)—Offset 80C4h

#### Access Method

**Type:** Memory Mapped I/O Register  
(Size: 32 bits)

**Offset:** [MBAR] + 80C4h

**MBAR Type:** PCI Configuration Register (Size: 64 bits)

**MBAR Reference:** [B:0, D:20, F:0] + 10h

**Default:** 004A4008h

### 18.7.152 High Speed TT Bandwidth Overload (HOST\_BW\_OV\_HS\_REG)–Offset 80C8h

**MBAR Reference:** [B:0, D:20, F:0] + 10h

[illegible]

Intel Atom® Processor E3800 Product Family  
Datasheet  
2293

### 18.7.161 USB2 Port Link Control 1 (USB2\_LINK\_MGR\_CTRL\_REG1)— Offset 80F0h

This set of registers is used to control the USB set of timers. They are spread over 4 registers each 32 bits wide.

#### Access Method

**Type:** Memory Mapped I/O Register  
(Size: 32 bits)

**Offset:** [MBAR] + 80F0h

**MBAR Type:** PCI Configuration Register (Size: 64 bits)

**MBAR Reference:** [B:0, D:20, F:0] + 10h

**Default:** 310003A0h

### 18.7.162 USB2 Port Link Control 2 (USB2\_LINK\_MGR\_CTRL\_REG2)—Offset 80F4h

This set of registers is used to control the USB set of timers. They are spread over 4 registers each 32 bits wide.

#### Access Method

**Type:** Memory Mapped I/O Register  
(Size: 32 bits)

**Offset:** [MBAR] + 80F4h

**MBAR Type:** PCI Configuration Register (Size: 64 bits)

**MBAR Reference:** [B:0, D:20, F:0] + 10h

**Default:** 80C40620h

### 18.7.173 Power Scheduler Control-2 (PWR\_SCHED\_CTRL2)—Offset 8144h

These bit enable by EP type those EPs classes that are considered for determining next periodic active interval for pre-wake of the periodic\_active signal. EP classes that are disabled may never be observed in setting of the periodic\_active signal.

| Bit Range | Default & Access | Field Name (ID): Description                                                       |

### 18.7.174 Latency Tolerance Control 0 (HOST\_IF\_LAT\_TOL\_CTRL\_REG0)—Offset 8150h

The Latency Tolerance Control Register is used by SW to control which BELT is returned when this register is read. SW shall write to this register to program a Slot-ID, Port-ID and BELT Select to determine which BELT is selected. When this register is read the selected BELT is returned.

| 24        | 1b<br>RW         | <p><b>Enable L1 exit notification to SNPS PCIe core (EN_L1_EXIT_NOTIF_PCIE):</b> This bit enables a L1 exit notification to SNPS PCIe core. There is a case where USB ports have waked up and AUX PM module has started the wakeup process. The AUX PM control state got into a wait for P0 state because it needs to wait until PCIe core to signal powerdown state change. Due to the fact that the core is in D3Hot, there is no run_stop bit set such that no internal interrupt will be fired. This causes the LTSSM of PCIe stayed in L1 even though AUX PM has known that it needs an L1 exit. This bit works together with bit21 of this register.</p> <ul style="list-style-type: none"> <li>1 = enables this feature</li> <li>0 = disables this feature.</li> </ul> <p><b>Power Well:</b> SUS</p> |

### 18.7.190 Debug Capability ID Register (DCID)—Offset 8480h

The Debug Capability *ID Register* links the USB Debug Capability into the xHCI list of Extended Capabilities and defines its basic capabilities. This register is modified and maintained by BIOS.

#### Access Method

**Type:** Memory Mapped I/O Register  
(Size: 32 bits)

**Offset:** [MBAR] + 8480h

**MBAR Type:** PCI Configuration Register (Size: 64 bits)

**MBAR Reference:** [B:0, D:20, F:0] + 10h

**Default:** 0005000Ah

### 18.7.194 Debug Capability Event Ring Dequeue Pointer Register (DCERDP)—Offset 8498h

The *Debug Capability Event Ring Dequeue Pointer Register* is written by software to define the Debug Capability Event Ring Dequeue Pointer location to the xHC. Software updates this pointer when it has finished the evaluation of an Event(s) on the Debug Capability Event Ring.

#### Access Method

**Type:** Memory Mapped I/O Register  
(Size: 64 bits)

**Offset:** [MBAR] + 8498h

**MBAR Type:** PCI Configuration Register (Size: 64 bits)

**MBAR Reference:** [B:0, D:20, F:0] + 10h

**Default:** 0000000000000000h

### 18.7.196 Debug Capability Status Register (DCST)—Offset 84A4h

The *Debug Capability Status Register* reports capability related status information to software.

#### Access Method

**Type:** Memory Mapped I/O Register  
(Size: 32 bits)

**Offset:** [MBAR] + 84A4h

**MBAR Type:** PCI Configuration Register (Size: 64 bits)

**MBAR Reference:** [B:0, D:20, F:0] + 10h

**Default:** 00000000h

| 0         | 0b<br>RO         | <b>Event Ring Not Empty (ERNE):</b> When '1', this field indicates that the Debug Capability Event Ring has a Transfer Event on it. It is automatically cleared to '0' by the xHC when the Debug Capability Event Ring is empty, i.e. the Debug Capability Enqueue Pointer is equal to the <i>Debug Capability Event Ring Dequeue Pointer</i> register.<br><b>Power Well:</b> Core |

### 18.7.197 Debug Capability Port Status and Control Register (DCPORTSC)—Offset 84A8h

The fields of the *Debug Capability PORTSC Register* are defined below and provide information about the state of the Root Hub port that is assigned to the Debug Capability. Note that the fields in this register function differently than those in a normal *Port Status and Control Register* (described in section 5.4.8) because the Root Hub port assigned to the Debug Capability is acting as an Upstream Facing Port, not a Downstream Facing Port.

#### Access Method

## 18.7.199 Debug Capability Device Descriptor Info Register 1 (DCDDI1)—Offset 84B8h

The *Debug Capability Device Descriptor Register 1* identifies the Device Protocol and Vendor ID values that shall be reported by DbC in its Device Descriptor when it is enumerated by a Debug Host. Refer to section 9.6.1, Table 9-8 in the USB3 spec. This register shall be initialized before enabling the DbC (DCE = '1').

### Access Method

**Type:** Memory Mapped I/O Register  
(Size: 32 bits)

**Offset:** [MBAR] + 84B8h

**MBAR Type:** PCI Configuration Register (Size: 64 bits)

**MBAR Reference:** [B:0, D:20, F:0] + 10h

**Default:** 00000000h

| 6         | 0b<br>RW         | <p><b>Parity Error Response (PER_0):</b> When set to 1, the USB2 Host Controller will check for correct parity (on its internal interface) and halt operation when bad parity is detected during the data phase as recommended by the EHCI specification. If it detects bad parity on the address or command phases when this bit is set to 1, the host controller does not take the cycle, halts the host controller (if currently not halted) and sets the host system error bit in the USBSTS register. Note that this applies to both requests and completions from the system interface. See section 9.19.2.4 for information regarding parity errors detected by the Prefetch DMA Engine. This bit must be set in order for the parity errors to generate SERR#.</p> <p><b>Power Well:</b> Core</p> |

| 2         | 0b<br>RW         | <p><b>Bus Master Enable (BME_0):</b> When set, bus mastering from EHCI is allowed, and will generate memory reads and writes for USB transfers. Notes on the EHC implementation: - Writes to change this bit occur immediately. Specifically, a write followed by a read will return the updated value. - When the BME bit is changed from 1 to 0, the EHC will cease accessing main memory within 2 microframes (250 usec). During this time, any number of reads and/or writes to memory may occur. - Clearing the BME bit shuts down the EHC DMA engines in the same manner that clearing the Run/Stop does. However, the schedule status bits and the HCHalted bit do not change based on the BME value.</p> <p><b>Power Well:</b> Core</p>                                                           |

| 18:16     | 011b<br>RW/L     | <b>Version (VERS_0):</b> Version: The Intel EHC reports 011, indicating that it complies with Revision 1.21 of the PCI Power Management Specification. Note: As contingency plan, the bit can be reverted by BIOS to 010b to support PCI PM Revision 1.1, by manipulating the offset80h Access Control register's WRT_RDONLY bit.<br><b>Power Well:</b> Core                                                                                                                                                                                                                                                                                                                                                                                                               |
| 15:8      | 58h<br>RW/L      | <b>Next Item Pointer #1 (PM_NEXT_0):</b> This register defaults to 58h, which indicates that the next capability registers begin at configuration offset 58h. This register is writable when the WRT_RDONLY bit is set. This allows BIOS to effectively hide the Debug Port capability registers, if necessary. This register should only be written during system initialization before the plug-and-play software has enabled any master-initiated traffic. Values of 58h implies Debug Port and FLR capabilities visible 98h implies Debug Port invisible, next capability is FLR 00h implies that both Debug port and FLR capability are hidden Note that this value is never expected to be programmed. Reset: core well, but not D3-to-D0<br><b>Power Well:</b> Core |

| 1:0       | 00b<br>RW        | <p><b>PowerState (PWRST_0):</b> This 2-bit field is used both to determine the current power state of EHC function and to set a new power state. The definition of the field values are: 00b - D0 state 11b - D3hot state If software attempts to write a value of 10b or 01b in to this field, the write operation must complete normally; however, the data is discarded and no state change occurs. When in the D3hot state, the accesses to the EHC memory range must not be accepted; but the configuration space must still be accessible. When not in the D0 state, the generation of the interrupt output is blocked. Specifically, the PIRQ[H] is not asserted when not in the D0 state. When software changes this value from the D3hot state to the D0 state, an internal warm (soft) reset is generated, and software must re-initialize the function.</p> <p><b>Power Well:</b> Resume</p> |

| 3:0       | 8h<br>RW         | <p><b>N_PORTS (NPORTS_0):</b> This field specifies the number of physical downstream ports implemented on this host controller. The value of this field determines how many port registers are addressable in the Operational Register Space. Valid values are in the range of 1H to FH. The default value for the EHCI controller indicates 8 ports. BIOS may overwrite the default value to properly describe the board or chip SKU . (please refer to RMH Configuration Details in section 1.23.2). A zero in this field is undefined. Integrated RMH - If USB<sub>R</sub> is disabled, this should be updated by BIOS to 2 such that the EHC reports 2ports to be default, port 0 assigned to the RMH and port 1 assigned to the debug device. If USB-R is enabled, the number reported should be updated to 3 by BIOS (port 2 will be assigned to USB-R in this case) Legacy Mode - The default value for the EHCI controller indicates 8 ports. If USB-R support is enabled, BIOS should account for the additional ports in calculating the value to write to this field.</p> <p><b>Power Well:</b> Resume</p> |

| 7:4       | 8h<br>RO                 | <b>Isochronous Scheduling Threshold (IST_0):</b> This field indicates, relative to the current position of the executing host controller, where software can reliably update the isochronous schedule. When bit [7] is zero, the value of the least significant 3 bits indicates the number of micro-frames a host controller hold a set of isochronous data structures (one or more) before flushing the state. When bit [7] is a one, then host software assumes the host controller may cache an isochronous data structure for an entire frame. Refer to the EHCI specification for details on how software uses this information for scheduling isochronous transfers. The Intel USB2 hardwires this field to 8h.<br><br><b>Power Well:</b> Resume |

| 6         | 0b<br>RW         | <p><b>Interrupt on Async Advance Doorbell (IAAD_0):</b> This bit is used as a doorbell by software to tell the host controller to issue an interrupt the next time it advances asynchronous schedule. Software must write a 1 to this bit to ring the doorbell. When the host controller has evicted all appropriate cached schedule state, it sets the Interrupt on Async Advance status bit in the USBSTS register. If the Interrupt on Async Advance Enable bit in the USBINTR register is a one then the host controller will assert an interrupt at the next interrupt threshold. See the EHCI specification for operational details. The host controller sets this bit to a zero after it has set the Interrupt on Async Advance status bit in the USBSTS register to a one. Software should not write a one to this bit when the asynchronous schedule is disabled. Doing so will yield undefined results.</p> <p><b>Power Well:</b> Core</p> |

| 1         | 0b<br>RW         | <p><b>Host Controller Reset (HCRESET_0):</b> This control bit used by software to reset the host controller. The effects of this on Root Hub registers are similar to a Chip Hardware Reset. When software writes a one to this bit, the Host Controller resets its internal pipelines, timers, counters, state machines, etc. to their initial value. Any transaction currently in progress on USB is immediately terminated. A USB reset is not driven on downstream ports. Note: PCI Configuration registers and Host Controller Capability Registers are not affected by this reset. All operational registers, including port registers and port state machines are set to their initial values. Port ownership will be disowned by the host controller(s), with the side effects described in the EHCI spec. Software must reinitialize the host controller in order to return the host controller to an operational state. This bit is set to zero by the Host Controller when the reset process is complete. Software cannot terminate the reset process early by writing a zero to this register. Software should not set this bit to a one when the HCHalted bit in the USBSTS register is a zero. Attempting to reset an actively running host controller will result in undefined behavior. This reset must be used to leave EHCI port test modes.</p> <p><b>Power Well:</b> Core</p> |

|-----------|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4         | 0b<br>RWC        | <p><b>Host System Error (HSE_0):</b> The Host Controller sets this bit to 1 when a serious error occurs during a host system access involving the Host Controller module. Memory read cycles initiated by the EHC that receive any status other than Successful will result in this bit being set. When this error occurs, the Host Controller clears the Run/Stop bit in the Command register to prevent further execution of the scheduled TDs. A hardware interrupt is generated to the system (if enabled in the Interrupt Enable Register).</p> <p><b>Power Well:</b> Core</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 3         | 0b<br>RWC        | <p><b>Frame List Rollover (FLR_0):</b> The Host Controller sets this bit to a one when the Frame List Index (see Section 9.3.2.4) rolls over from its maximum value to zero. Since the USB2 SIP only supports the 1024-entry Frame List Size, the Frame List Index rolls over every time FRNUM[13] toggles.</p> <p><b>Power Well:</b> Core</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 2         | 0b<br>RWC        | <p><b>Port Change Detect (PCD_0):</b> The Host Controller sets this bit to a one when any port for which the Port Owner bit is set to zero has a change bit transition from a zero to a one or a Force Port Resume bit transition from a zero to a one as a result of a J-K transition detected on a suspended port. This bit will also be set as a result of the Connect Status Change being set to a one after system software has relinquished ownership of a connected port by writing a zero to a port's Port Owner bit. This bit is allowed to be maintained in the Auxiliary power well. Alternatively, it is also acceptable that on a D3 to D0 transition of the EHCI HC device, this bit is loaded with the OR of all of the PORTSC change bits (including: Force port resume, over-current change, enable/disable change and connect status change). Regardless of the implementation, whenever this bit is readable (i.e., in the D0 state), it must provide a valid view of the Port Status registers.</p> <p><b>Power Well:</b> Core</p> |
| 1         | 0b<br>RWC        | <p><b>USB Error Interrupt (USBERRINT_0):</b> The Host Controller sets this bit to 1 when completion of a USB transaction results in an error condition (e.g., error counter underflow). If the TD on which the error interrupt occurred also had its IOC bit set, both this bit and Bit 0 are set. See the EHCI specification for a list of the USB errors that will result in this interrupt being asserted.</p> <p><b>Power Well:</b> Core</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 0         | 0b<br>RWC        | <p><b>USB Interrupt (USBINT_0):</b> The Host Controller sets this bit to 1 on the completion of a USB transaction, which results in the retirement of a Transfer Descriptor that had its IOC bit set. The Host Controller also sets this bit to 1 when a short packet is detected (actual number of bytes received was less than the expected number of bytes).</p> <p><b>Power Well:</b> Core</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## 18.9.6 USB2 Interrupt Enable (USB2INTR)—Offset 28h

### Access Method

**Type:** Memory Mapped I/O Register  
(Size: 32 bits)

**Offset:** [MBAR] + 28h

**MBAR Type:** PCI Configuration Register (Size: 32 bits)

**MBAR Reference:** [B:0, D:29, F:0] + 10h

**Default:** 00000000h

| 8         | 0b<br>RW         | <p><b>Port Reset (PORTRST_P0_0):</b> 1=Port is in Reset. 0=Port is not in Reset. Default = 0. When software writes a one to this bit (from a zero), the bus reset sequence as defined in the USB Specification Revision 2.0 is started. Software writes a zero to this bit to terminate the bus reset sequence. Software must keep this bit at a one long enough to guarantee the reset sequence, as specified in the USB Specification Revision 2.0, completes. Note: when software writes this bit to a one, it must also write a zero to the Port Enable bit. Note that when software writes a zero to this bit there may be a delay before the bit status changes to a zero. The bit status will not read as a zero until after the reset has completed. If the port is in high-speed mode after reset is complete, the host controller will automatically enable this port (e.g. set the Port Enable bit to a one). A host controller must terminate the reset and stabilize the state of the port within 2 milliseconds of software transitioning this bit from a one to a zero. For example: if the port detects that the attached device is high-speed during reset, then the host controller must have the port in the enabled state within 2ms of software writing this bit to a zero. The HCHalted bit in the USB2STS register should be a zero before software attempts to use this bit. The host controller may hold Port Reset asserted to a one when the HCHALTED bit is a one. The Run/Stop bit in the Command Register must be set in order for the Port Reset bit to be cleared.</p> <p><b>Power Well:</b> Resume</p> |
| 7         | 0b<br>RW         | <p><b>Suspend (SUSP_P0_0):</b> 1=Port in suspend state. 0=Port not in suspend state. Port Enabled Bit and Suspend bit of this register define the port states as follows: Bits [Port Enabled, Suspend] Port State 0X Disable 10 Enable 11 Suspend When in suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction, if a transaction was in progress when this bit was written to a 1. In the suspend state, the port is sensitive to resume detection. Note that the bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress on the USB. A write of zero to this bit is ignored by the host controller. The host controller will unconditionally set this bit to a zero when: Software sets the Force Port Resume bit to a zero (from a one). Software sets the Port Reset bit to a one (from a zero). If host software sets this bit to a one when the port is not enabled (i.e. Port enabled bit is a zero) the results are undefined.</p> <p><b>Power Well:</b> Resume</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Bit Range | Default & Access | Field Name (ID): Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| 6         | 0b<br>RW         | <p><b>Force Port Resume (FPR_P0_0):</b> 1= Resume detected/driven on port. 0=No resume (K-state) detected/driven on port. This functionality defined for manipulating this bit depends on the value of the Suspend bit. For example, if the port is not suspended (Suspend and Enabled bits are a one) and software transitions this bit to a one, then the effects on the bus are undefined. Software sets this bit to a 1 to drive resume signaling. The Host Controller sets this bit to a 1 if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one because a J-to-K transition is detected, the Port Change Detect bit in the USBSTS register is also set to a one. If software sets this bit to a one, the host controller must not set the Port Change Detect bit. Note that when the EHCI controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. Software must appropriately time the Resume and set this bit to a zero when the appropriate amount of time has elapsed. Writing a zero (from one) causes the port to return to high-speed mode (forcing the bus below the port into a high-speed idle). This bit will remain a one until the port has switched to the high-speed idle. The host controller must complete this transition within 2 milliseconds of software setting this bit to a zero.</p> <p><b>Power Well:</b> Resume</p> |
| 5         | 0b<br>RWC        | <p><b>Over-current Change (OCC_P0_0):</b> This bit gets set to a one when there is a change to the Over-current Active bit. Software clears this bit by writing a one to this bit position. The functionality of this bit is not dependent upon the port owner.</p> <p><b>Power Well:</b> Resume</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 4         | 0b<br>RO         | <p><b>Over-current Active (OACT_P0_0):</b> 1=This port currently has an over-current condition. 0=This port does not have an over-current condition. This bit will automatically transition from a one to a zero when the over current condition is removed. The functionality of this bit is not dependent upon the port owner. The Intel EHC automatically disables the port when the over-current active bit is '1'.</p> <p><b>Power Well:</b> Resume</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 3         | 0b<br>RWC        | <p><b>Port Enable/Disable Change (PEDC_P0_0):</b> 1=Port enabled/disabled status has changed. 0=No change. For the root hub, this bit gets set to a one only when a port is disabled due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification for the definition of a port error). This bit is not set due to the Disabled-to-Enabled transition, nor due to a disconnect. Software clears this bit by writing a 1 to it.</p> <p><b>Power Well:</b> Resume</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| 8         | 0b<br>RW         | <b>Port Reset (PORTRST_P0_0):</b> 1=Port is in Reset. 0=Port is not in Reset. Default = 0. When software writes a one to this bit (from a zero), the bus reset sequence as defined in the USB Specification Revision 2.0 is started. Software writes a zero to this bit to terminate the bus reset sequence. Software must keep this bit at a one long enough to guarantee the reset sequence, as specified in the USB Specification Revision 2.0, completes. Note: when software writes this bit to a one, it must also write a zero to the Port Enable bit. Note that when software writes a zero to this bit there may be a delay before the bit status changes to a zero. The bit status will not read as a zero until after the reset has completed. If the port is in high-speed mode after reset is complete, the host controller will automatically enable this port (e.g. set the Port Enable bit to a one). A host controller must terminate the reset and stabilize the state of the port within 2 milliseconds of software transitioning this bit from a one to a zero. For example: if the port detects that the attached device is high-speed during reset, then the host controller must have the port in the enabled state within 2ms of software writing this bit to a zero. The HCHalted bit in the USB2STS register should be a zero before software attempts to use this bit. The host controller may hold Port Reset asserted to a one when the HCHALTED bit is a one. The Run/Stop bit in the Command Register must be set in order for the Port Reset bit to be cleared.<br><br><b>Power Well:</b> Resume |

| 7         | 0b<br>RW         | <p><b>Suspend (SUSP_P0_0):</b> 1=Port in suspend state. 0=Port not in suspend state. Port Enabled Bit and Suspend bit of this register define the port states as follows: Bits [Port Enabled, Suspend] Port State 0X Disable 10 Enable 11 Suspend When in suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction, if a transaction was in progress when this bit was written to a 1. In the suspend state, the port is sensitive to resume detection. Note that the bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress on the USB. A write of zero to this bit is ignored by the host controller. The host controller will unconditionally set this bit to a zero when: Software sets the Force Port Resume bit to a zero (from a one). Software sets the Port Reset bit to a one (from a zero). If host software sets this bit to a one when the port is not enabled (i.e. Port enabled bit is a zero) the results are undefined.</p> <p><b>Power Well:</b> Resume</p>                                                                                                                                                                                                                                                                                                                                                                                                 |
| 6         | 0b<br>RW         | <p><b>Force Port Resume (FPR_P0_0):</b> 1= Resume detected/driven on port. 0=No resume (K-state) detected/driven on port. This functionality defined for manipulating this bit depends on the value of the Suspend bit. For example, if the port is not suspended (Suspend and Enabled bits are a one) and software transitions this bit to a one, then the effects on the bus are undefined. Software sets this bit to a 1 to drive resume signaling. The Host Controller sets this bit to a 1 if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one because a J-to-K transition is detected, the Port Change Detect bit in the USBSTS register is also set to a one. If software sets this bit to a one, the host controller must not set the Port Change Detect bit. Note that when the EHCI controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. Software must appropriately time the Resume and set this bit to a zero when the appropriate amount of time has elapsed. Writing a zero (from one) causes the port to return to high-speed mode (forcing the bus below the port into a high-speed idle). This bit will remain a one until the port has switched to the high-speed idle. The host controller must complete this transition within 2 milliseconds of software setting this bit to a zero.</p> <p><b>Power Well:</b> Resume</p> |
| 5         | 0b<br>RWC        | <p><b>Over-current Change (OCC_P0_0):</b> This bit gets set to a one when there is a change to the Over-current Active bit. Software clears this bit by writing a one to this bit position. The functionality of this bit is not dependent upon the port owner.</p> <p><b>Power Well:</b> Resume</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| 8         | 0b<br>RW         | <p><b>Port Reset (PORTRST_P0_0):</b> 1=Port is in Reset. 0=Port is not in Reset. Default = 0. When software writes a one to this bit (from a zero), the bus reset sequence as defined in the USB Specification Revision 2.0 is started. Software writes a zero to this bit to terminate the bus reset sequence. Software must keep this bit at a one long enough to guarantee the reset sequence, as specified in the USB Specification Revision 2.0, completes. Note: when software writes this bit to a one, it must also write a zero to the Port Enable bit. Note that when software writes a zero to this bit there may be a delay before the bit status changes to a zero. The bit status will not read as a zero until after the reset has completed. If the port is in high-speed mode after reset is complete, the host controller will automatically enable this port (e.g. set the Port Enable bit to a one). A host controller must terminate the reset and stabilize the state of the port within 2 milliseconds of software transitioning this bit from a one to a zero. For example: if the port detects that the attached device is high-speed during reset, then the host controller must have the port in the enabled state within 2ms of software writing this bit to a zero. The HCHalted bit in the USB2STS register should be a zero before software attempts to use this bit. The host controller may hold Port Reset asserted to a one when the HCHALTED bit is a one. The Run/Stop bit in the Command Register must be set in order for the Port Reset bit to be cleared.</p> <p><b>Power Well:</b> Resume</p> |
| 7         | 0b<br>RW         | <p><b>Suspend (SUSP_P0_0):</b> 1=Port in suspend state. 0=Port not in suspend state. Port Enabled Bit and Suspend bit of this register define the port states as follows: Bits [Port Enabled, Suspend] Port State 0X Disable 10 Enable 11 Suspend When in suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction, if a transaction was in progress when this bit was written to a 1. In the suspend state, the port is sensitive to resume detection. Note that the bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress on the USB. A write of zero to this bit is ignored by the host controller. The host controller will unconditionally set this bit to a zero when: Software sets the Force Port Resume bit to a zero (from a one). Software sets the Port Reset bit to a one (from a zero). If host software sets this bit to a one when the port is not enabled (i.e. Port enabled bit is a zero) the results are undefined.</p> <p><b>Power Well:</b> Resume</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| 6         | 0b<br>RW         | <p><b>Force Port Resume (FPR_P0_0):</b> 1= Resume detected/driven on port. 0=No resume (K-state) detected/driven on port. This functionality defined for manipulating this bit depends on the value of the Suspend bit. For example, if the port is not suspended (Suspend and Enabled bits are a one) and software transitions this bit to a one, then the effects on the bus are undefined. Software sets this bit to a 1 to drive resume signaling. The Host Controller sets this bit to a 1 if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one because a J-to-K transition is detected, the Port Change Detect bit in the USBSTS register is also set to a one. If software sets this bit to a one, the host controller must not set the Port Change Detect bit. Note that when the EHCI controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. Software must appropriately time the Resume and set this bit to a zero when the appropriate amount of time has elapsed. Writing a zero (from one) causes the port to return to high-speed mode (forcing the bus below the port into a high-speed idle). This bit will remain a one until the port has switched to the high-speed idle. The host controller must complete this transition within 2 milliseconds of software setting this bit to a zero.</p> <p><b>Power Well:</b> Resume</p> |
| 5         | 0b<br>RWC        | <p><b>Over-current Change (OCC_P0_0):</b> This bit gets set to a one when there is a change to the Over-current Active bit. Software clears this bit by writing a one to this bit position. The functionality of this bit is not dependent upon the port owner.</p> <p><b>Power Well:</b> Resume</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 4         | 0b<br>RO         | <p><b>Over-current Active (OACT_P0_0):</b> 1=This port currently has an over-current condition. 0=This port does not have an over-current condition. This bit will automatically transition from a one to a zero when the over current condition is removed. The functionality of this bit is not dependent upon the port owner. The Intel EHC automatically disables the port when the over-current active bit is '1'.</p> <p><b>Power Well:</b> Resume</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 3         | 0b<br>RWC        | <p><b>Port Enable/Disable Change (PEDC_P0_0):</b> 1=Port enabled/disabled status has changed. 0=No change. For the root hub, this bit gets set to a one only when a port is disabled due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification for the definition of a port error). This bit is not set due to the Disabled-to-Enabled transition, nor due to a disconnect. Software clears this bit by writing a 1 to it.</p> <p><b>Power Well:</b> Resume</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| 21        | 0b<br>RW         | <p><b>Wake on Disconnect Enable (WKDSCNTE_P0_0):</b> Writing this bit to a one enables the port to be sensitive to device disconnects as wake-up events. When enabled to do so, the EHC sets the PME Status bit in the Power Management Control/Status Register (offset 54, bit 15) when the Current Connect Status changes from connected to disconnected (i.e., bit 0 of this register changes from 1 to 0).</p> <p><b>Power Well:</b> Resume</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 20        | 0b<br>RW         | <p><b>Wake on Connect Enable (WKCNNTE_P0_0):</b> Writing this bit to a one enables the port to be sensitive to device connects as wake-up events. When enabled to do so, the EHC sets the PME Status bit in the Power Management Control/Status Register (offset 54, bit 15) when the Current Connect Status changes from disconnected to connected (i.e., bit 0 of this register changes from 0 to 1).</p> <p><b>Power Well:</b> Resume</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 19:16     | 0h<br>RW         | <p><b>Port Test Control (PTC_P0_0):</b> When this field is zero, the port is NOT operating in a test mode. A non-zero value indicates that it is operating in test mode and the specific test mode is indicated by the specific value. The encoding of the test mode bits are (0110b - 1111b are reserved): Bits Test Mode 0000b Test mode not enabled 0001b Test J_STATE- During this test mode the hardware forces pre-emphasis disabled to the AFE if bit 29 of the USB2 Safe Mode Register is set (config offset FCh.bit 29) 0010b Test K_STATE- During this test mode the hardware forces pre-emphasis disabled to the AFE if bit 29 of the USB2 Safe Mode Register is set (config offset FCh.bit 29) 0011b Test SE0_NAK 0100b Test Packet 0101b Test FORCE_ENABLE Refer to USB Specification Revision 2.0, Chapter 7 and the EHCI specification, Chapter 4 for details on each test mode. The EHC does not support the option to run the port tests while the Run/Stop bit is a one.</p> <p><b>Power Well:</b> Resume</p> |
| 15:14     | 00b<br>RW        | <p><b>Port Indicator Control (PIC_P0_0):</b> Writing to these bits directly controls the corresponding LED output pins. Bit 15 is inverted to generate USBLEDG#(n) where n is the port number. Bit 14 is inverted to generate USBLEDA#(n). Software is responsible for controlling these as specified in the USB Specification Revision 2.0. Bit Value Meaning 00b Port indicators are off 01b Amber 10b Green 11b Undefined The Intel EHC only supports bit value of 00b. Other values will result in unspecified behavior.</p> <p><b>Power Well:</b> Resume</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 13        | 1b<br>RW         | <p><b>Port Owner (PO_P0_0):</b> This bit unconditionally goes to a 0b when the Configure Flag makes a 0b to 1b transition. This bit unconditionally goes to 1b whenever the Configure Flag bit is zero. System software uses this field to release ownership of the port to a selected host controller (in the event that the attached device is not a high-speed device). Software writes a one to this bit when the attached device is not a high-speed device. A one in this bit means that a companion host controller owns and controls the port. See Section 4 of the EHCI Specification for operational details.</p> <p><b>Power Well:</b> Resume</p>                                                                                                                                                                                                                                                                                                                                                                    |

| Bit Range | Default & Access | Field Name (ID): Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| 8         | 0b<br>RW         | <b>Port Reset (PORTRST_P0_0):</b> 1=Port is in Reset. 0=Port is not in Reset. Default = 0. When software writes a one to this bit (from a zero), the bus reset sequence as defined in the USB Specification Revision 2.0 is started. Software writes a zero to this bit to terminate the bus reset sequence. Software must keep this bit at a one long enough to guarantee the reset sequence, as specified in the USB Specification Revision 2.0, completes. Note: when software writes this bit to a one, it must also write a zero to the Port Enable bit. Note that when software writes a zero to this bit there may be a delay before the bit status changes to a zero. The bit status will not read as a zero until after the reset has completed. If the port is in high-speed mode after reset is complete, the host controller will automatically enable this port (e.g. set the Port Enable bit to a one). A host controller must terminate the reset and stabilize the state of the port within 2 milliseconds of software transitioning this bit from a one to a zero. For example: if the port detects that the attached device is high-speed during reset, then the host controller must have the port in the enabled state within 2ms of software writing this bit to a zero. The HCHalted bit in the USB2STS register should be a zero before software attempts to use this bit. The host controller may hold Port Reset asserted to a one when the HCHALTED bit is a one. The Run/Stop bit in the Command Register must be set in order for the Port Reset bit to be cleared.<br><br><b>Power Well:</b> Resume |

| Bit Range | Default & Access | Field Name (ID): Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| 7         | 0b<br>RW         | <p><b>Suspend (SUSP_P0_0):</b> 1=Port in suspend state. 0=Port not in suspend state. Port Enabled Bit and Suspend bit of this register define the port states as follows: Bits [Port Enabled, Suspend] Port State 0X Disable 10 Enable 11 Suspend When in suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction, if a transaction was in progress when this bit was written to a 1. In the suspend state, the port is sensitive to resume detection. Note that the bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress on the USB. A write of zero to this bit is ignored by the host controller. The host controller will unconditionally set this bit to a zero when: Software sets the Force Port Resume bit to a zero (from a one). Software sets the Port Reset bit to a one (from a zero). If host software sets this bit to a one when the port is not enabled (i.e. Port enabled bit is a zero) the results are undefined.</p> <p><b>Power Well:</b> Resume</p>                                                                                                                                                                                                                                                                                                                                                                                                 |
| 6         | 0b<br>RW         | <p><b>Force Port Resume (FPR_P0_0):</b> 1= Resume detected/driven on port. 0=No resume (K-state) detected/driven on port. This functionality defined for manipulating this bit depends on the value of the Suspend bit. For example, if the port is not suspended (Suspend and Enabled bits are a one) and software transitions this bit to a one, then the effects on the bus are undefined. Software sets this bit to a 1 to drive resume signaling. The Host Controller sets this bit to a 1 if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one because a J-to-K transition is detected, the Port Change Detect bit in the USBSTS register is also set to a one. If software sets this bit to a one, the host controller must not set the Port Change Detect bit. Note that when the EHCI controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. Software must appropriately time the Resume and set this bit to a zero when the appropriate amount of time has elapsed. Writing a zero (from one) causes the port to return to high-speed mode (forcing the bus below the port into a high-speed idle). This bit will remain a one until the port has switched to the high-speed idle. The host controller must complete this transition within 2 milliseconds of software setting this bit to a zero.</p> <p><b>Power Well:</b> Resume</p> |
| 5         | 0b<br>RWC        | <p><b>Over-current Change (OCC_P0_0):</b> This bit gets set to a one when there is a change to the Over-current Active bit. Software clears this bit by writing a one to this bit position. The functionality of this bit is not dependent upon the port owner.</p> <p><b>Power Well:</b> Resume</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

This bit will automatically transition from a one to a zero when the over current condition is removed. The functionality of this bit is not dependent upon the port owner. The Intel EHC automatically disables the port when the over-current active bit is '1'.</p> <p><b>Power Well:</b> Resume</p>                                                                                                                                                           |
| 3         | 0b<br>RWC        | <p><b>Port Enable/Disable Change (PEDC_P0_0):</b> 1=Port enabled/disabled status has changed. 0=No change. For the root hub, this bit gets set to a one only when a port is disabled due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification for the definition of a port error). This bit is not set due to the Disabled-to-Enabled transition, nor due to a disconnect. Software clears this bit by writing a 1 to it.</p> <p><b>Power Well:</b> Resume</p>                                                                                                            |

| 8         | 0b<br>RW         | <p><b>Port Reset (PORTRST_P0_0):</b> 1=Port is in Reset. 0=Port is not in Reset. Default = 0. When software writes a one to this bit (from a zero), the bus reset sequence as defined in the USB Specification Revision 2.0 is started. Software writes a zero to this bit to terminate the bus reset sequence. Software must keep this bit at a one long enough to guarantee the reset sequence, as specified in the USB Specification Revision 2.0, completes. Note: when software writes this bit to a one, it must also write a zero to the Port Enable bit. Note that when software writes a zero to this bit there may be a delay before the bit status changes to a zero. The bit status will not read as a zero until after the reset has completed. If the port is in high-speed mode after reset is complete, the host controller will automatically enable this port (e.g. set the Port Enable bit to a one). A host controller must terminate the reset and stabilize the state of the port within 2 milliseconds of software transitioning this bit from a one to a zero. For example: if the port detects that the attached device is high-speed during reset, then the host controller must have the port in the enabled state within 2ms of software writing this bit to a zero. The HCHalted bit in the USB2STS register should be a zero before software attempts to use this bit. The host controller may hold Port Reset asserted to a one when the HCHALTED bit is a one. The Run/Stop bit in the Command Register must be set in order for the Port Reset bit to be cleared.</p> <p><b>Power Well:</b> Resume</p> |
| 7         | 0b<br>RW         | <p><b>Suspend (SUSP_P0_0):</b> 1=Port in suspend state. 0=Port not in suspend state. Port Enabled Bit and Suspend bit of this register define the port states as follows: Bits [Port Enabled, Suspend] Port State 0X Disable 10 Enable 11 Suspend When in suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction, if a transaction was in progress when this bit was written to a 1. In the suspend state, the port is sensitive to resume detection. Note that the bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress on the USB. A write of zero to this bit is ignored by the host controller. The host controller will unconditionally set this bit to a zero when: Software sets the Force Port Resume bit to a zero (from a one). Software sets the Port Reset bit to a one (from a zero). If host software sets this bit to a one when the port is not enabled (i.e. Port enabled bit is a zero) the results are undefined.</p> <p><b>Power Well:</b> Resume</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Bit Range | Default & Access | Field Name (ID): Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| 6         | 0b<br>RW         | <p><b>Force Port Resume (FPR_P0_0):</b> 1= Resume detected/driven on port. 0=No resume (K-state) detected/driven on port. This functionality defined for manipulating this bit depends on the value of the Suspend bit. For example, if the port is not suspended (Suspend and Enabled bits are a one) and software transitions this bit to a one, then the effects on the bus are undefined. Software sets this bit to a 1 to drive resume signaling. The Host Controller sets this bit to a 1 if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one because a J-to-K transition is detected, the Port Change Detect bit in the USBSTS register is also set to a one. If software sets this bit to a one, the host controller must not set the Port Change Detect bit. Note that when the EHCI controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. Software must appropriately time the Resume and set this bit to a zero when the appropriate amount of time has elapsed. Writing a zero (from one) causes the port to return to high-speed mode (forcing the bus below the port into a high-speed idle). This bit will remain a one until the port has switched to the high-speed idle. The host controller must complete this transition within 2 milliseconds of software setting this bit to a zero.</p> <p><b>Power Well:</b> Resume</p> |
| 5         | 0b<br>RWC        | <p><b>Over-current Change (OCC_P0_0):</b> This bit gets set to a one when there is a change to the Over-current Active bit. Software clears this bit by writing a one to this bit position. The functionality of this bit is not dependent upon the port owner.</p> <p><b>Power Well:</b> Resume</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 4         | 0b<br>RO         | <p><b>Over-current Active (OACT_P0_0):</b> 1=This port currently has an over-current condition. 0=This port does not have an over-current condition. This bit will automatically transition from a one to a zero when the over current condition is removed. The functionality of this bit is not dependent upon the port owner. The Intel EHC automatically disables the port when the over-current active bit is '1'.</p> <p><b>Power Well:</b> Resume</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 3         | 0b<br>RWC        | <p><b>Port Enable/Disable Change (PEDC_P0_0):</b> 1=Port enabled/disabled status has changed. 0=No change. For the root hub, this bit gets set to a one only when a port is disabled due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification for the definition of a port error). This bit is not set due to the Disabled-to-Enabled transition, nor due to a disconnect. Software clears this bit by writing a 1 to it.</p> <p><b>Power Well:</b> Resume</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| 8         | 0b<br>RW         | <b>Port Reset (PORTRST_P0_0):</b> 1=Port is in Reset. 0=Port is not in Reset. Default = 0. When software writes a one to this bit (from a zero), the bus reset sequence as defined in the USB Specification Revision 2.0 is started. Software writes a zero to this bit to terminate the bus reset sequence. Software must keep this bit at a one long enough to guarantee the reset sequence, as specified in the USB Specification Revision 2.0, completes. Note: when software writes this bit to a one, it must also write a zero to the Port Enable bit. Note that when software writes a zero to this bit there may be a delay before the bit status changes to a zero. The bit status will not read as a zero until after the reset has completed. If the port is in high-speed mode after reset is complete, the host controller will automatically enable this port (e.g. set the Port Enable bit to a one). A host controller must terminate the reset and stabilize the state of the port within 2 milliseconds of software transitioning this bit from a one to a zero. For example: if the port detects that the attached device is high-speed during reset, then the host controller must have the port in the enabled state within 2ms of software writing this bit to a zero. The HCHalted bit in the USB2STS register should be a zero before software attempts to use this bit. The host controller may hold Port Reset asserted to a one when the HCHALTED bit is a one. The Run/Stop bit in the Command Register must be set in order for the Port Reset bit to be cleared.<br><br><b>Power Well:</b> Resume |

| Bit Range | Default & Access | Field Name (ID): Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| 7         | 0b<br>RW         | <p><b>Suspend (SUSP_P0_0):</b> 1=Port in suspend state. 0=Port not in suspend state. Port Enabled Bit and Suspend bit of this register define the port states as follows: Bits [Port Enabled, Suspend] Port State 0X Disable 10 Enable 11 Suspend When in suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction, if a transaction was in progress when this bit was written to a 1. In the suspend state, the port is sensitive to resume detection. Note that the bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress on the USB. A write of zero to this bit is ignored by the host controller. The host controller will unconditionally set this bit to a zero when: Software sets the Force Port Resume bit to a zero (from a one). Software sets the Port Reset bit to a one (from a zero). If host software sets this bit to a one when the port is not enabled (i.e. Port enabled bit is a zero) the results are undefined.</p> <p><b>Power Well:</b> Resume</p>                                                                                                                                                                                                                                                                                                                                                                                                 |
| 6         | 0b<br>RW         | <p><b>Force Port Resume (FPR_P0_0):</b> 1= Resume detected/driven on port. 0=No resume (K-state) detected/driven on port. This functionality defined for manipulating this bit depends on the value of the Suspend bit. For example, if the port is not suspended (Suspend and Enabled bits are a one) and software transitions this bit to a one, then the effects on the bus are undefined. Software sets this bit to a 1 to drive resume signaling. The Host Controller sets this bit to a 1 if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one because a J-to-K transition is detected, the Port Change Detect bit in the USBSTS register is also set to a one. If software sets this bit to a one, the host controller must not set the Port Change Detect bit. Note that when the EHCI controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. Software must appropriately time the Resume and set this bit to a zero when the appropriate amount of time has elapsed. Writing a zero (from one) causes the port to return to high-speed mode (forcing the bus below the port into a high-speed idle). This bit will remain a one until the port has switched to the high-speed idle. The host controller must complete this transition within 2 milliseconds of software setting this bit to a zero.</p> <p><b>Power Well:</b> Resume</p> |
| 5         | 0b<br>RWC        | <p><b>Over-current Change (OCC_P0_0):</b> This bit gets set to a one when there is a change to the Over-current Active bit. Software clears this bit by writing a one to this bit position. The functionality of this bit is not dependent upon the port owner.</p> <p><b>Power Well:</b> Resume</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| 19:16     | 0h<br>RW         | <p><b>Port Test Control (PTC_P0_0):</b> When this field is zero, the port is NOT operating in a test mode. A non-zero value indicates that it is operating in test mode and the specific test mode is indicated by the specific value. The encoding of the test mode bits are (0110b - 1111b are reserved): Bits Test Mode 0000b Test mode not enabled 0001b Test J_STATE- During this test mode the hardware forces pre-emphasis disabled to the AFE if bit 29 of the USB2 Safe Mode Register is set (config offset FCh.bit 29) 0010b Test K_STATE- During this test mode the hardware forces pre-emphasis disabled to the AFE if bit 29 of the USB2 Safe Mode Register is set (config offset FCh.bit 29) 0011b Test SE0_NAK 0100b Test Packet 0101b Test FORCE_ENABLE Refer to USB Specification Revision 2.0, Chapter 7 and the EHCI specification, Chapter 4 for details on each test mode. The EHC does not support the option to run the port tests while the Run/Stop bit is a one.</p> <p><b>Power Well:</b> Resume</p> |
| 15:14     | 00b<br>RW        | <p><b>Port Indicator Control (PIC_P0_0):</b> Writing to these bits directly controls the corresponding LED output pins. Bit 15 is inverted to generate USBLEDG#(n) where n is the port number. Bit 14 is inverted to generate USBLEDA#(n). Software is responsible for controlling these as specified in the USB Specification Revision 2.0. Bit Value Meaning 00b Port indicators are off 01b Amber 10b Green 11b Undefined The Intel EHC only supports bit value of 00b. Other values will result in unspecified behavior.</p> <p><b>Power Well:</b> Resume</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 13        | 1b<br>RW         | <p><b>Port Owner (PO_P0_0):</b> This bit unconditionally goes to a 0b when the Configure Flag makes a 0b to 1b transition. This bit unconditionally goes to 1b whenever the Configure Flag bit is zero. System software uses this field to release ownership of the port to a selected host controller (in the event that the attached device is not a high-speed device). Software writes a one to this bit when the attached device is not a high-speed device. A one in this bit means that a companion host controller owns and controls the port. See Section 4 of the EHCI Specification for operational details.</p> <p><b>Power Well:</b> Resume</p>                                                                                                                                                                                                                                                                                                                                                                    |
| 12        | 1b<br>RO         | <p><b>Port Power (PP_P0_0):</b> Hard-wired with a value of '1' on the Intel EHC. This indicates that the port does have power.</p> <p><b>Power Well:</b> Resume</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 11:10     | 00b<br>RO        | <p><b>Line Status (LS_P0_0):</b> These bits reflect the current logical levels of the D+ (bit 11) and D- (bit 10) signal lines. These bits are used for detection of low-speed USB devices prior to the port reset and enable sequence. This field is valid only when the port enable bit is zero and the current connect status bit is set to a one. The encoding of the bits are: Bits(11:10) USB State Interpretation 00b SE0 Not Low-speed device, perform EHCI reset 10b J-state Not Low-speed device, perform EHCI reset 01b K-state Low-speed device, release ownership of port 11b Undefined Not Low-speed device, perform EHCI reset</p> <p><b>Power Well:</b> Resume</p>                                                                                                                                                                                                                                                                                                                                              |

| 8         | 0b<br>RW         | <p><b>Port Reset (PORTRST_P0_0):</b> 1=Port is in Reset. 0=Port is not in Reset. Default = 0. When software writes a one to this bit (from a zero), the bus reset sequence as defined in the USB Specification Revision 2.0 is started. Software writes a zero to this bit to terminate the bus reset sequence. Software must keep this bit at a one long enough to guarantee the reset sequence, as specified in the USB Specification Revision 2.0, completes. Note: when software writes this bit to a one, it must also write a zero to the Port Enable bit. Note that when software writes a zero to this bit there may be a delay before the bit status changes to a zero. The bit status will not read as a zero until after the reset has completed. If the port is in high-speed mode after reset is complete, the host controller will automatically enable this port (e.g. set the Port Enable bit to a one). A host controller must terminate the reset and stabilize the state of the port within 2 milliseconds of software transitioning this bit from a one to a zero. For example: if the port detects that the attached device is high-speed during reset, then the host controller must have the port in the enabled state within 2ms of software writing this bit to a zero. The HCHalted bit in the USB2STS register should be a zero before software attempts to use this bit. The host controller may hold Port Reset asserted to a one when the HCHALTED bit is a one. The Run/Stop bit in the Command Register must be set in order for the Port Reset bit to be cleared.</p> <p><b>Power Well:</b> Resume</p> |
| 7         | 0b<br>RW         | <p><b>Suspend (SUSP_P0_0):</b> 1=Port in suspend state. 0=Port not in suspend state. Port Enabled Bit and Suspend bit of this register define the port states as follows: Bits [Port Enabled, Suspend] Port State 0X Disable 10 Enable 11 Suspend When in suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction, if a transaction was in progress when this bit was written to a 1. In the suspend state, the port is sensitive to resume detection. Note that the bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress on the USB. A write of zero to this bit is ignored by the host controller. The host controller will unconditionally set this bit to a zero when: Software sets the Force Port Resume bit to a zero (from a one). Software sets the Port Reset bit to a one (from a zero). If host software sets this bit to a one when the port is not enabled (i.e. Port enabled bit is a zero) the results are undefined.</p> <p><b>Power Well:</b> Resume</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Bit Range | Default & Access | Field Name (ID): Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 6         | 0b<br>RW         | <p><b>Force Port Resume (FPR_P0_0):</b> 1= Resume detected/driven on port. 0=No resume (K-state) detected/driven on port. This functionality defined for manipulating this bit depends on the value of the Suspend bit. For example, if the port is not suspended (Suspend and Enabled bits are a one) and software transitions this bit to a one, then the effects on the bus are undefined. Software sets this bit to a 1 to drive resume signaling. The Host Controller sets this bit to a 1 if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one because a J-to-K transition is detected, the Port Change Detect bit in the USBSTS register is also set to a one. If software sets this bit to a one, the host controller must not set the Port Change Detect bit. Note that when the EHCI controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. Software must appropriately time the Resume and set this bit to a zero when the appropriate amount of time has elapsed. Writing a zero (from one) causes the port to return to high-speed mode (forcing the bus below the port into a high-speed idle). This bit will remain a one until the port has switched to the high-speed idle. The host controller must complete this transition within 2 milliseconds of software setting this bit to a zero.</p> <p><b>Power Well:</b> Resume</p> |
| 5         | 0b<br>RWC        | <p><b>Over-current Change (OCC_P0_0):</b> This bit gets set to a one when there is a change to the Over-current Active bit. Software clears this bit by writing a one to this bit position. The functionality of this bit is not dependent upon the port owner.</p> <p><b>Power Well:</b> Resume</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 4         | 0b<br>RO         | <p><b>Over-current Active (OACT_P0_0):</b> 1=This port currently has an over-current condition. 0=This port does not have an over-current condition. This bit will automatically transition from a one to a zero when the over current condition is removed. The functionality of this bit is not dependent upon the port owner. The Intel EHC automatically disables the port when the over-current active bit is '1'.</p> <p><b>Power Well:</b> Resume</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 3         | 0b<br>RWC        | <p><b>Port Enable/Disable Change (PEDC_P0_0):</b> 1=Port enabled/disabled status has changed. 0=No change. For the root hub, this bit gets set to a one only when a port is disabled due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification for the definition of a port error). This bit is not set due to the Disabled-to-Enabled transition, nor due to a disconnect. Software clears this bit by writing a 1 to it.</p> <p><b>Power Well:</b> Resume</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| 8         | 0b<br>RW         | <b>Port Reset (PORTRST_P0_0):</b> 1=Port is in Reset. 0=Port is not in Reset. Default = 0. When software writes a one to this bit (from a zero), the bus reset sequence as defined in the USB Specification Revision 2.0 is started. Software writes a zero to this bit to terminate the bus reset sequence. Software must keep this bit at a one long enough to guarantee the reset sequence, as specified in the USB Specification Revision 2.0, completes. Note: when software writes this bit to a one, it must also write a zero to the Port Enable bit. Note that when software writes a zero to this bit there may be a delay before the bit status changes to a zero. The bit status will not read as a zero until after the reset has completed. If the port is in high-speed mode after reset is complete, the host controller will automatically enable this port (e.g. set the Port Enable bit to a one). A host controller must terminate the reset and stabilize the state of the port within 2 milliseconds of software transitioning this bit from a one to a zero. For example: if the port detects that the attached device is high-speed during reset, then the host controller must have the port in the enabled state within 2ms of software writing this bit to a zero. The HCHalted bit in the USB2STS register should be a zero before software attempts to use this bit. The host controller may hold Port Reset asserted to a one when the HCHALTED bit is a one. The Run/Stop bit in the Command Register must be set in order for the Port Reset bit to be cleared.<br><br><b>Power Well:</b> Resume |

| Bit Range | Default & Access | Field Name (ID): Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| 7         | 0b<br>RW         | <p><b>Suspend (SUSP_P0_0):</b> 1=Port in suspend state. 0=Port not in suspend state. Port Enabled Bit and Suspend bit of this register define the port states as follows: Bits [Port Enabled, Suspend] Port State 0X Disable 10 Enable 11 Suspend When in suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction, if a transaction was in progress when this bit was written to a 1. In the suspend state, the port is sensitive to resume detection. Note that the bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress on the USB. A write of zero to this bit is ignored by the host controller. The host controller will unconditionally set this bit to a zero when: Software sets the Force Port Resume bit to a zero (from a one). Software sets the Port Reset bit to a one (from a zero). If host software sets this bit to a one when the port is not enabled (i.e. Port enabled bit is a zero) the results are undefined.</p> <p><b>Power Well:</b> Resume</p>                                                                                                                                                                                                                                                                                                                                                                                                 |
| 6         | 0b<br>RW         | <p><b>Force Port Resume (FPR_P0_0):</b> 1= Resume detected/driven on port. 0=No resume (K-state) detected/driven on port. This functionality defined for manipulating this bit depends on the value of the Suspend bit. For example, if the port is not suspended (Suspend and Enabled bits are a one) and software transitions this bit to a one, then the effects on the bus are undefined. Software sets this bit to a 1 to drive resume signaling. The Host Controller sets this bit to a 1 if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one because a J-to-K transition is detected, the Port Change Detect bit in the USBSTS register is also set to a one. If software sets this bit to a one, the host controller must not set the Port Change Detect bit. Note that when the EHCI controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. Software must appropriately time the Resume and set this bit to a zero when the appropriate amount of time has elapsed. Writing a zero (from one) causes the port to return to high-speed mode (forcing the bus below the port into a high-speed idle). This bit will remain a one until the port has switched to the high-speed idle. The host controller must complete this transition within 2 milliseconds of software setting this bit to a zero.</p> <p><b>Power Well:</b> Resume</p> |
| 5         | 0b<br>RWC        | <p><b>Over-current Change (OCC_P0_0):</b> This bit gets set to a one when there is a change to the Over-current Active bit. Software clears this bit by writing a one to this bit position. The functionality of this bit is not dependent upon the port owner.</p> <p><b>Power Well:</b> Resume</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

This bit will automatically transition from a one to a zero when the over current condition is removed. The functionality of this bit is not dependent upon the port owner. The Intel EHC automatically disables the port when the over-current active bit is '1'.</p> <p><b>Power Well:</b> Resume</p>                                                                                                                                                           |
| 3         | 0b<br>RWC        | <p><b>Port Enable/Disable Change (PEDC_P0_0):</b> 1=Port enabled/disabled status has changed. 0=No change. For the root hub, this bit gets set to a one only when a port is disabled due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification for the definition of a port error). This bit is not set due to the Disabled-to-Enabled transition, nor due to a disconnect. Software clears this bit by writing a 1 to it.</p> <p><b>Power Well:</b> Resume</p>                                                                                                            |

| 3:0       | 0000b<br>RW      | <p><b>DATA_LEN_CNT (DATALENCNT_0):</b> This field is used to indicate the size of the data to be transferred. Reset default = 0h. For write operations, this field is set by software to indicate to the hardware how many bytes of data in Data Buffer are to be transferred to the console. A value of 0h indicates that a zero-length packet should be sent. A value of 1-8 indicates 1-8 bytes are to be transferred. Values 9-Fh are illegal and how hardware behaves if used is undefined. For read operations, this field is set by hardware to indicate to software how many bytes in Data Buffer are valid in response to a read operation. A value of 0h indicates that a zero length packet was returned and the state of Data Buffer is not defined. A value of 1-8 indicates 1-8 bytes were received. Hardware is not allowed to return values 9-Fh. The transferring of data always starts with byte 0 in the data area and moves toward byte 7 until the transfer size is reached.</p> <p><b>Power Well:</b> Core</p> |

### 18.9.21 USB PIDs Register (DP USB PIDs)—Offset A4h

## Access Method

**Type:** Memory Mapped I/O Register  
(Size: 32 bits)

**Offset:** [MBAR] + A4h

**MBAR Type:** PCI Configuration Register (Size: 32 bits)

**MBAR Reference:** [B:0, D:29, F:0] + 10h

**Default:** 00000000h

| 23:16     | 00h<br>RO        | <p><b>RECEIVED_PID_STS (RECEIVED_PID_STS_0):</b> The hardware updates this field with the received PID for transactions in either direction. When the controller is writing data, this field is updated with the handshake PID that is received from the device. When the host controller is reading data, this field is updated with the data packet PID (if the device sent data), or the handshake PID (if the device NAKs the request). This field is valid when the hardware clears the GO_DONE#_CNT bit. Reset Default = 0.</p> <p><b>Power Well:</b> Core</p> |
| 15:8      | 00h<br>RW        | <p><b>SEND_PID_CNT (SEND_PID_CNT_0):</b> The hardware sends this PID to begin the data packet when sending data to USB (ie. WRITE_READ#_CNT is asserted). Software will typically set this field to either DATA0 or DATA1 PID values. Reset Default = 0</p> <p><b>Power Well:</b> Core</p>                                                                                                                                                                                                                                                                           |
| 7:0       | 00h<br>RW        | <p><b>TOKEN_PID_CNT (TOKEN_PID_CNT_0):</b> The hardware sends this PID as the Token PID for each USB transaction. Software will typically set this field to either IN, OUT or SETUP PID values. Reset Default = 0.</p> <p><b>Power Well:</b> Core</p>                                                                                                                                                                                                                                                                                                                |

### 18.9.23 Debug Port Config Register (DP\_CFG)—Offset B0h

#### Access Method

**Type:** Memory Mapped I/O Register  
(Size: 32 bits)

**Offset:** [MBAR] + B0h

**MBAR Type:** PCI Configuration Register (Size: 32 bits)

**MBAR Reference:** [B:0, D:29, F:0] + 10h

**Default:** 00007F01h

|      |    |    |    |                |    |   |   |                 |

### 18.10.5 USB2 PER PORT (USB2\_PER\_PORT\_LANE4)—Offset 4500h

#### Access Method

**Type:** Message Bus Register  
(Size: 32 bits)

**Offset:** [Port: 0x43] + 4500h

#### Op Codes:

h - Read, h - Write

**Default:** 0004F201h

## 19 USB Device Controller Interfaces (3.0, ULPI)

The SoC implements a single USB 3.0 device controller, where the platform acts as a peripheral to another device or another PC.

The USB Device controller supports connections at Super Speed (3.0) on the USB3DEV interface, and High and Full speeds (2.0/1.x) on the ULPI interface. To support High and Full Speed devices on ULPI, an external PHY is required.

**Note:** The ULPI interface must be implemented even if only SuperSpeed support is required. The USB3DEV interface will not operate if the ULPI interface is disabled.

### 19.0.1 Signal Descriptions

See [Chapter 2, “Physical Interfaces”](#) for additional details.

The signal description table has the following headings:

- **Signal Name:** The name of the signal/pin
- **Direction:** The buffer direction can be either input, output, or I/O (bidirectional)
- **Platform Power:** The reference power plane.
- **Description:** A brief explanation of the signal’s function

Table 218. USB ULPI Device Signals

| Signal Name        | Direction<br>Plat. Power | Description                                                                                                                                                                                                                                                      |
|--------------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| USB_ULPI_CLK       | I<br>V1P8A               | <b>Interface Clock</b><br>By default, control and data signals are synchronous to clock.                                                                                                                                                                         |
| USB_ULPI_DATA[7:0] | I/O<br>V1P8A             | <b>Bi-directional data bus</b><br>Driven low by the Link during idle. The Link starts a transfer by sending a non-zero pattern. The PHY must assert USB_ULPI_DIR before using the data bus. A turnaround cycle is required every time that USB_ULPI_DIR toggles. |
| USB_ULPI_DIR       | I<br>V1P8A               | <b>Direction of the data bus</b><br>By default, USB_ULPI_DIR is low and the PHY listens for non-zero data from the Link. The PHY asserts USB_ULPI_DIR to get control of the data bus.                                                                            |
| USB_ULPI_NXT       | I<br>V1P8A               | <b>Next Data</b><br>The PHY drives USB_ULPI_NXT high to throttle the data bus                                                                                                                                                                                    |
| USB_ULPI_STP       | O<br>V1P8A               | <b>Stop data</b><br>The Link drives USB_ULPI_STP high to signal the end of its data stream. The Link can also drive USB_ULPI_STP high to request data bus access from the PHY                                                                                    |
| USB_ULPI_REFCLK    | O<br>V1P8A               | <b>Reference clock</b><br>ULPI reference clock for external PHY                                                                                                                                                                                                  |
| USB_ULPI_RST#      | O<br>V1P8A               | <b>Reset</b><br>Used to reset the external PHY. Not part of ULPI specification. Optionally used by driver.                                                                                                                                                       |

## 19.1 USB Device Controller

The USB device controller can control one USB 3.0 Device port. Either a combo SS + ULPI Device port, or UPLI only port. It supports hosts conforming to USB 3.0 at bit rates up to 5 Gbps on USB3DEV interface as well as USB 2.0 hosts at up to 480 Mbps via a PHY on ULPI.

### 19.1.1 Features

Features supported by the Device Controller include:

- Enumerated by both ACPI and PCI. The USB3 device subsystem is designed to appear to the OS as a true PCI device. It will also support ACPI-enumerated methods.
- Device controller registers and data structures are implemented as extensions to the EHCI programmers interface.
- Support for LPM (Link Power Management)

Some of the key features of the ULPI device controller are:

- Supports up to 8 endpoints when acting as device
- 8-bit data interface transmitted at 60 MHz ULPI clock

**Note:** Recommended not to disconnect the connection when a debug session is in progress.

### 19.1.2 Power Management Features

The USB 3.0 device subsystem supports the following device power states:

- D0: Functional and highest power state.
- RTD3 (D3): Software managed deepest low power state in which state is saved/restored if needed prior to entry/exit

#### 19.1.2.1 D0

This is the Functional and highest power state. The USB 3.0 device subsystem is in this state when the USB link is in U0 (U0 is the normal operational state where packets can be transmitted and received).

#### 19.1.2.2 D3

D3 is a low power state that is used when the link is suspended; for example, U3 (U3 is a link state where a device is put into a suspend state. Significant link and device powers are saved).

This is a software directed state in which the controller is either power gated or the power is disabled.

### 19.1.3 Interrupts

A Functional Interrupt is generated by the logic in the USB device controller core to indicate the occurrence of an event needing application intervention. The design of the USB device core is such that events such as "link change" that would traditionally trigger an interrupt through an interrupt status register, are instead delivered to an 'Event buffer' in host memory, together with an interrupt indicating this.

## 19.3 Register Map

See Chapters [Section 3, "Register Access Methods" on page 69](#) and [Section 4, "Mapping Address Spaces" on page 75](#) for additional information. Also note that the device controller also contains both device and host registers. The host functionality of this controller is not fully functional and should not be used. See the USB Host chapter for host controllers.

| Bit Range | Default & Access | Description                      |
|-----------|------------------|----------------------------------|
| 15:8      | 00h<br>RO        | <b>LATTIMER:</b> Reserved.       |
| 7:0       | 00h<br>RW        | <b>CACHELINE_SIZE:</b> Reserved. |

#### 19.4.5 reg\_BAR\_type (BAR)—Offset 10h

## BAR -Base Address Register

## Access Method

**Type:** PCI Configuration Register  
(Size: 32 bits)

**BAR:** [B:0, D:22, F:0] + 10h

**Default:** 00000000h

[illegible]

| Bit Range | Default & Access | Description                     |
|-----------|------------------|---------------------------------|
| 31:12     | 00000h<br>RW     | <b>BASEADDR:</b> Reserved.      |
| 11:4      | 00h<br>RO        | <b>SIZEINDICATOR:</b> Reserved. |
| 3         | 0h<br>RO         | <b>PREFETCHABLE:</b> Reserved.  |
| 2:1       | 0h<br>RO         | <b>TYPE:</b> Reserved.          |
| 0         | 0h<br>RO         | <b>MESSAGE_SPACE:</b> Reserved. |

#### 19.4.6 reg\_BAR1\_type (BAR1)—Offset 14h

BAR1 -Base Address Register1

## Access Method

**Type:** PCI Configuration Register  
(Size: 32 bits)

**BAR1:** [B:0, D:22, F:0] + 14h

**Default:** 00000000h

| Bit Range | Default & Access | Description                      |
|-----------|------------------|----------------------------------|
| 31:12     | 00000h<br>RW     | <b>BASEADDR1:</b> Reserved.      |
| 11:4      | 00h<br>RO        | <b>SIZEINDICATOR1:</b> Reserved. |
| 3         | 0h<br>RO         | <b>PREFETCHABLE1:</b> Reserved.  |
| 2:1       | 0h<br>RO         | <b>TYPE1:</b> Reserved.          |
| 0         | 0h<br>RO         | <b>MESSAGE_SPACE1:</b> Reserved. |

#### 19.4.7 reg\_SUBSYSTEMID\_type (SUBSYSTEMID)—Offset 2Ch

SUBSYSTEMID -Subsystem Vendor and Subsystem ID

## Access Method

**Type:** PCI Configuration Register  
(Size: 32 bits)

**SUBSYSTEMID:** [B:0, D:22, F:0] + 2Ch

**Default:** 00000000h

| Bit Range | Default & Access | Description                         |
|-----------|------------------|-------------------------------------|
| 31:16     | 0000h<br>RW/O    | <b>SUBSYSTEMID:</b> Reserved.       |
| 15:0      | 0000h<br>RW/O    | <b>SUBSYSTEMVENDORID:</b> Reserved. |

### 19.4.10 reg\_INTERRUPTREG\_type (INTERRUPTREG)—Offset 3Ch

INTERRUPTREG - Interrupt Register

#### Access Method

**Type:** PCI Configuration Register  
(Size: 32 bits)

**INTERRUPTREG:** [B:0, D:22, F:0] + 3Ch

**Default:** 00000100h

|         |    |    |    |           |    |   |   |         |
|---------|----|----|----|-----------|----|---|---|---------|
| 31      | 28 | 24 | 20 | 16        | 12 | 8 | 4 | 0       |
| 0       | 0  | 0  | 0  | 0         | 0  | 0 | 0 | 0       |
| 0       | 0  | 0  | 0  | 0         | 0  | 0 | 1 | 0       |
| 0       | 0  | 0  | 0  | 0         | 0  | 0 | 0 | 0       |
| MAX_LAT |    |    |    | MIN_GNT   |    |   |   | INTLINE |
|         |    |    |    | Reserved0 |    |   |   | INTPIN  |

| Bit Range | Default & Access | Description                 |
|-----------|------------------|-----------------------------|
| 31:24     | 00h<br>RO        | <b>MAX_LAT:</b> Reserved.   |
| 23:16     | 00h<br>RO        | <b>MIN_GNT:</b> Reserved.   |
| 15:12     | 0h<br>RO         | <b>Reserved0:</b> Reserved. |
| 11:8      | 1h<br>RO         | <b>INTPIN:</b> Reserved.    |
| 7:0       | 00h<br>RW        | <b>INTLINE:</b> Reserved.   |

### 19.4.11 reg\_POWERCAPID\_type (POWERCAPID)—Offset 80h

POWERCAPID - PowerManagement Capability ID

#### Access Method

**Type:** PCI Configuration Register  
(Size: 32 bits)

**POWERCAPID:** [B:0, D:22, F:0] + 80h

**Default:** 48030001h

|            |    |    |    |           |    |   |   |           |

## BAR -Base Address Register

**Type:** PCI Configuration Register  
(Size: 32 bits)

[illegible]

### 19.5.6 reg\_BAR1\_type (BAR1)—Offset 14h

## Access Method

**Type:** PCI Configuration Register  
(Size: 32 bits)

October 2018  
Document Number: 538136, Rev. 4.3

| Bit Range | Default & Access | Description                         |
|-----------|------------------|-------------------------------------|
| 31:16     | 0000h<br>RW/O    | <b>SUBSYSTEMID:</b> Reserved.       |
| 15:0      | 0000h<br>RW/O    | <b>SUBSYSTEMVENDORID:</b> Reserved. |

## Access Method

**EXPANSION ROM BASEADDR:** [B:0, D:22, F:0] + 30h

|                    |    |    |    |    |    |   |   |   |
|--------------------|----|----|----|----|----|---|---|---|
| 31                 | 28 | 24 | 20 | 16 | 12 | 8 | 4 | 0 |
| 0                  | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 |
| EXPANSTON_ROM_BASE |    |    |    |    |    |   |   |   |

| Bit Range | Default & Access | Description                          |
|-----------|------------------|--------------------------------------|
| 31:0      | 00000000h<br>RO  | <b>EXPANSION_ROM_BASE:</b> Reserved. |

### 19.5.9 reg\_CAPABILITYPTR\_type (CAPABILITYPTR)—Offset 34h

## CAPABILITYPTR - Capabilities Pointer

## Access Method

**CAPABILITYPTR:** [B:0, D:22, F:0] + 34h

|           |    |    |    |    |    |   |              |   |
|-----------|----|----|----|----|----|---|--------------|---|
| 31        | 28 | 24 | 20 | 16 | 12 | 8 | 4            | 0 |
| 0         | 0  | 0  | 0  | 0  | 0  | 0 | 0            | 0 |
| Reserved0 |    |    |    |    |    |   | CAPPTR_POWER |   |

| Bit Range | Default & Access | Description                    |
|-----------|------------------|--------------------------------|
| 31:8      | 000000h<br>RO    | <b>Reserved0:</b> Reserved.    |
| 7:0       | 80h<br>RO        | <b>CAPPTR_POWER:</b> Reserved. |

### 19.5.10 reg\_INTERRUPTREG\_type (INTERRUPTREG)—Offset 3Ch

INTERRUPTREG - Interrupt Register

#### Access Method

**Type:** PCI Configuration Register  
(Size: 32 bits)

**INTERRUPTREG:** [B:0, D:22, F:0] + 3Ch

**Default:** 00000100h

|         |    |    |    |           |    |   |   |         |
|---------|----|----|----|-----------|----|---|---|---------|
| 31      | 28 | 24 | 20 | 16        | 12 | 8 | 4 | 0       |
| 0       | 0  | 0  | 0  | 0         | 0  | 0 | 0 | 0       |
| 0       | 0  | 0  | 0  | 0         | 0  | 0 | 1 | 0       |
| 0       | 0  | 0  | 0  | 0         | 0  | 0 | 0 | 0       |
| MAX_LAT |    |    |    | MIN_GNT   |    |   |   | INTPIN  |
|         |    |    |    | Reserved0 |    |   |   | INTLINE |

| Bit Range | Default & Access | Description                 |
|-----------|------------------|-----------------------------|
| 31:24     | 00h<br>RO        | <b>MAX_LAT:</b> Reserved.   |

## 19.6.1 CAPLENGTH—Offset 0h

This register is used as an offset to add to register base to find the beginning of the Operational Register Space.

### Access Method

**Type:** Memory Mapped I/O Register  
(Size: 32 bits)

**CAPLENGTH:** [BAR] + 0h

**BAR Type:** PCI Configuration Register (Size: 32 bits)

**BAR Reference:** [B:0, D:22, F:0] + 10h

| Bit Range | Default & Access | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 18:8      | 1h<br>RO         | <b>MAXINTRS:</b> Number of Interrupters (MaxIntrs). This field specifies the number of Interrupters implemented on this host controller. Each Interrupter may be allocated to a MSI or MSI-X vector and controls its generation and moderation. The value of this field determines how many Interrupter Register Sets are addressable in the Runtime Register Space (refer to section 5.5). Valid values are in the range of 1h to 400h. A 0 in this field is undefined. |
| 7:0       | 7fh<br>RO        | <b>MAXSLOTS:</b> Number of Device Slots (MaxSlots). This field specifies the maximum number of Device Context Structures and Doorbell Array entries this host controller can support. Valid values are in the range of 1 to 255. The value of 0 is reserved.                                                                                                                                                                                                             |

### 19.6.3 HCSPARAMS2—Offset 8h

Host Controller Structural Parameters 2

#### Access Method

**Type:** Memory Mapped I/O Register  
(Size: 32 bits)

**HCSPARAMS2:** [BAR] + 8h

**BAR Type:** PCI Configuration Register (Size: 32 bits)

**BAR Reference:** [B:0, D:22, F:0] + 10h

**Default:** 140000F1h

| 5         | 0h<br>RO         | <b>LHRC:</b> Light HC Reset Capability (LHRC). This flag indicates whether the host controller implementation supports a Light Host Controller Reset. A 1 in this bit indicates that Light Host Controller Reset is supported. A 0 in this bit indicates that Light Host Controller Reset is not supported. The value of this flag affects the functionality of the Light Host Controller Reset (LHCRST) flag in the USBCMD register (refer to Section 5.4.1).                                                                                                                                                                                                                                        |
| 4         | 0h<br>RO         | <b>PIND:</b> Port Indicators (PIND). This bit indicates whether the xHC root hub ports support port indicator control. When this bit is a 1, the port status and control registers include a read/writeable field for controlling the state of the port indicator. Refer to Section 5.4.8 for definition of the Port Indicator Control field.                                                                                                                                                                                                                                                                                                                                                         |
| 3         | 1h<br>RO         | <b>PPC:</b> Port Power Control (PPC). This flag indicates whether the host controller implementation includes port power control. A 1 in this bit indicates the ports have port power switches. A 0 in this bit indicates the port do not have port power switches. The value of this flag affects the functionality of the PP flag in each port status and control register (refer to Section 5.4.8).                                                                                                                                                                                                                                                                                                |
| 2         | 1h<br>RO         | <b>CSZ:</b> Context Size (CSZ). If this bit is set to 1, then the xHC uses 64 byte Context data structures. If this bit is cleared to 0, then the xHC uses 32 byte Context data structures. Note: This flag does not apply to Stream Contexts.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 1         | 0h<br>RO         | <b>BNC:</b> BW Negotiation Capability (BNC). This flag identifies whether the xHC has implemented the Bandwidth Negotiation. Values for this flag have the following interpretation: for Value 0 Description BW Negotiation not implemented. for Value 1 DescriptionBW Negotiation implemented. Refer to section 4.16 of xHCI specification for more information on Bandwidth Negotiation.                                                                                                                                                                                                                                                                                                            |
| 0         | 0h<br>RO         | <b>AC64:</b> 64-bit Addressing Capability (AC64). This flag documents the addressing range capability of this implementation. The value of this flag determines whether the xHC has implemented the high order 32 bits of 64 bit register and data structure pointer fields. Values for this flag have the following interpretation: for Value 0 Description 32-bit address memory pointers implemented. for Value 1 description 64-bit address memory pointers implemented. If 32-bit address memory pointers are implemented, the xHC shall ignore the high order 32 bits of 64 bit data structure pointer fields, and system software shall ignore the high order 32 bits of 64 bit xHC registers. |

| 8         | 0h<br>RW         | <b>CSS:</b> Controller Save State: This command is similar to the USB_CMD. CSS bit in host mode and initiates the save process. When software sets this bit to '1', the controller immediately sets DSTS.SSS to '1'. When the controller has finished the save process, it sets DSTS.SSS to '0'.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 7         | 0h<br>RW         | <b>LHCRST:</b> Light Host Controller Reset (LHCRST) RO or RW. Optional normative. Default = 0. If the Light HC Reset Capability (LHRC) bit in the HCCPARAMS register is 1, then this flag allows the driver to reset the xHC without affecting the state of the ports. A system software read of this bit as 0 indicates the Light Host Controller Reset has completed and it is safe for software to re-initialize the xHC. A software read of this bit as a 1 indicates the Light Host Controller Reset has not yet completed. If not implemented, a read of this flag shall always return a 0. All registers in the Aux Power well shall maintain the values that had been asserted prior to the Light Host Controller Reset. Refer to section 4.23.1 for more information. When this register is exposed by a Virtual Function (VF), this bit only generates a Light Reset to the xHC instance presented by the selected VF, e.g. Disable the VFs device slots and set the associated VF Run bit to Stopped. Refer to section 8 for more information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 6:4       | 0h<br>RO         | <b>RSVD7:</b> Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 3         | 0h<br>RW         | <b>HSEE:</b> Host System Error Enable (HSEE) RW. Default = 0. When this bit is a 1, and the HSE bit in the USBSTS register is a 1, the xHC shall assert out-of-band error signaling to the host. The signaling is acknowledged by software clearing the HSE bit. Refer to section 4.10.2.6 for more information. When this register is exposed by a Virtual Function (VF), the effect of the assertion of this bit on the Physical Function (PF0) is determined by the VMM. Refer to section 8 for more information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 2         | 0h<br>RW         | <b>INTE:</b> Interrupter Enable (INTE) RW. Default = 0. This bit provides system software with a means of enabling or disabling the host system interrupts generated by Interrupters. When this bit is a 1, then Interrupter host system interrupt generation is allowed, e.g. the xHC shall issue an interrupt at the next interrupt threshold if the host system interrupt mechanism (e.g. MSI, MSI-X, etc.) is enabled. The interrupt is acknowledged by a host system interrupt specific mechanism. When this register is exposed by a Virtual Function (VF), this bit only enables the set of Interrupters assigned to the selected VF. Refer to section 7.7.2 for more information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 1         | 0h<br>RW         | <b>HCIRST:</b> Host Controller Reset (HCIRST) RW. Default = 0. This control bit is used by software to reset the host controller. The effects of this bit on the xHC and the Root Hub registers are similar to a Chip Hardware Reset. When software writes a 1 to this bit, the Host Controller resets its internal pipelines, timers, counters, state machines, etc. to their initial value. Any transaction currently in progress on the USB is immediately terminated. A USB reset shall not be driven on USB2 downstream ports, however a Hot or Warm Reset shall be initiated on USB3 Root Hub downstream ports. PCI Configuration registers are not affected by this reset. All operational registers, including port registers and port state machines are set to their initial values. Software shall reinitialize the host controller as described in Section 4.1 in order to return the host controller to an operational state. This bit is cleared to 0 by the Host Controller when the reset process is complete. Software cannot terminate the reset process early by writing a 0 to this bit and shall not write any xHC Operational or Runtime registers until while HCIRST is 1. Note, the completion of the xHC reset process is not gated by the Root Hub port reset process. Software shall not set this bit to 1 when the HCHalted (HCH) bit in the USBSTS register is a 0. Attempting to reset an actively running host controller may result in undefined behavior. When this register is exposed by a Virtual Function (VF), this bit only resets the xHC instance presented by the selected VF. Refer to section 8 for more information. |

| Bit Range | Default & Access | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| 0         | 0h<br>RW         | <b>R_S:</b> Run/Stop (R/S) RW. Default = 0. 1 = Run. 0 = Stop. When set to a 1, the xHC proceeds with execution of the schedule. The xHC continues execution as long as this bit is set to a 1. When this bit is cleared to 0, the xHC completes any current or queued commands or TDs, and any USB transactions associated with them, then halts. Refer to section 5.4.1.1 for more information on how R/S shall be managed. The xHC shall halt within 16 ms. after software clears the Run/Stop bit if the above conditions have been met. The HCHalted (HCH) bit in the USBSTS register indicates when the xHC has finished its pending pipelined transactions and has entered the stopped state. Software shall not write a 1 to this flag unless the xHC is in the Halted state (i.e. HCH in the USBSTS register is 1). Doing so may yield undefined results. Writing a 0 to this flag when the xHC is in the Running state (i.e. HCH = 0) and any Event Rings are in the Event Ring Full state (refer to section 4.9.4) may result in lost events. When this register is exposed by a Virtual Function (VF), this bit only controls the run state of the xHC instance presented by the selected VF. Refer to section 8 for more information. |

## 19.6.10 USBSTS—Offset 24h

USB Command Register Bit Definitions

### Access Method

**Type:** Memory Mapped I/O Register  
(Size: 32 bits)

**USBSTS:** [BAR] + 24h

**BAR Type:** PCI Configuration Register (Size: 32 bits)

**BAR Reference:** [B:0, D:22, F:0] + 10h

**Default:** 00000001h

### 19.6.11 PAGESIZE—Offset 28h

Page Size Register Bit Definitions. This register is used by software to enable or disable the reporting of the reception of specific USB Device Notification Transaction Packets. A Notification Enable (Nx, where x = 0 to 15) flag is defined for each of the 16 possible device notification types. If a flag is set for a specific notification type, a Device Notification Event shall be generated when the respective notification packet is received. After reset all notifications are disabled. Refer to section 6.4.2.7. This register shall be written as a Dword. Byte writes produce undefined results.

#### Access Method

| 3         | 0h<br>RW         | <b>CRR:</b> Command Ring Running (CRR) - RO. Default = 0. This flag is set to 1 if the Run/Stop (R/S) bit is 1 and the Host Controller Doorbell register is written with the DB Reason field set to Host Controller Command. It is cleared to 0 when the Command Ring is stopped after writing a 1 to the Command Stop (CS) or Command Abort (CA) flags, or if the R/S bit is cleared to 0.                                                                                                                                                                                                                                                                                                                                                                                                    |
| 2         | 0h<br>RW         | <b>CA:</b> Command Abort (CA) - RW1S. Default = 0. Writing a 1 to this bit shall immediately terminate the currently executing command, stop the Command Ring, and generate a Command Completion Event with the Completion Code set to Command Ring Stopped. Refer to section 4.6.1.2 for more information on aborting a command. The next write to the Host Controller Doorbell with DB Reason field set to Host Controller Command shall restart the Command Ring operation. Writes to this flag are ignored by the xHC if Command Ring Running (CRR) = 0. Reading this bit always returns 0.                                                                                                                                                                                                |
| 1         | 0h<br>RW         | <b>CS:</b> Command Stop (CS) - RW1S. Default = 0. Writing a 1 to this bit shall stop the operation of the Command Ring after the completion of the currently executing command, and generate a Command Completion Event with the Completion Code set to Command Ring Stopped and the Command TRB Pointer set to the current value of the Command Ring Dequeue Pointer. Refer to section 4.6.1.1 for more information on stopping a command. The next write to the Host Controller Doorbell with DB Reason field set to Host Controller Command shall restart the Command Ring operation. Writes to this flag are ignored by the xHC if Command Ring Running (CRR) = 0. Reading this bit shall always return 0.                                                                                 |
| 0         | 0h<br>RW         | <b>RCS:</b> Ring Cycle State (RCS) - RW. This bit identifies the value of the xHC Consumer Cycle State (CCS) flag for the TRB referenced by the Command Ring Pointer. Refer to section 4.9.3 for more information. Writes to this flag are ignored if Command Ring Running (CRR) is 1. If the CRCR is written while the Command Ring is stopped (CRR = 0), then the value of this flag shall be used to fetch the first Command TRB the next time the Host Controller Doorbell register is written with the DB Reason field set to Host Controller Command. If the CRCR is not written while the Command Ring is stopped (CRR = 0), then the Command Ring shall begin fetching Command TRBs using the current value of the internal Command Ring CCS flag. Reading this flag always returns 0. |

This flag is set to 1 due to the following PLS transitions mentioned in the XHCI specification                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 21        | 0h<br>RW         | <b>PRC:</b> Port Reset Change (PRC) RW1CS. Default = 0. This flag is set to 1 due to a '1' to '0' transition of Port Reset (PR). e.g. when any reset processing (Warm or Hot) on this port is complete. Note that this flag shall not be set to 1 if the reset processing was forced to terminate due to software clearing PP or PED to '0'. 0 = No change. 1 = Reset complete. Software shall clear this bit by writing a '1' to it. Refer to section 4.19.5. Refer to section 4.19.2 for more information on change bit usage.                                                                                                |
| 20        | 0h<br>RW         | <b>OCC:</b> Over-current Change (OCC) RW1CS. Default = 0. This bit shall be set to a 1 when there is a 0 to 1 or 1 to 0 transition of Over-current Active (OCA). Software shall clear this bit by writing a 1 to it. Refer to section 4.19.2 for more information on change bit usage.                                                                                                                                                                                                                                                                                                                                          |
| 19        | 0h<br>RW         | <b>WRC:</b> Warm Port Reset Change (WRC) RW1CS/RsvdZ. Default = 0. This bit is set when Warm Reset processing on this port completes. 0 = No change. 1 = Warm Reset complete. Note that this flag shall not be set to 1 if the Warm Reset processing was forced to terminate due to software clearing PP or PED to '0'. Software shall clear this bit by writing a '1' to it. Refer to section 4.19.5.1. Refer to section 4.19.2 for more information on change bit usage. This bit only applies to USB3 protocol ports. For USB2 protocol ports it shall be RsvdZ.                                                             |
| 18        | 0h<br>RW         | <b>PEC:</b> Port Enabled/Disabled Change (PEC) RW1CS. Default = 0. 1 = change in PED. 0 = No change. Note that this flag shall not be set if the PED transition was due to software setting PP to 0. Software shall clear this bit by writing a 1 to it. Refer to section 4.19.2 for more information on change bit usage. For a USB2 protocol port, this bit shall be set to 1 only when the port is disabled due to the appropriate conditions existing at the EOF2 point (refer to section 11.8.1 of the USB2 Specification for the definition of a Port Error). For a USB3 protocol port, this bit shall never be set to 1. |

| Bit Range | Default & Access | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 17        | 0h<br>RW         | <b>CSC:</b> Connect Status Change (CSC) RW1CS. Default = 0. 1 = Change in CCS. 0 = No change. This flag indicates a change has occurred in the ports Current Connect Status (CCS) or Cold Attach Status (CAS) bits. Note that this flag shall not be set if the CCS transition was due to software setting PP to 0, or the CAS transition was due to software setting WPR to 1. The xHC sets this bit to 1 for all changes to the port device connect status, even if system software has not cleared an existing Connect Status Change. For example, the insertion status changes twice before system software has cleared the changed condition, root hub hardware will be setting an already-set bit (i.e., the bit will remain 1). Software shall clear this bit by writing a 1 to it. Refer to section 4.19.2 for more information on change bit usage.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 16        | 0h<br>RW         | <b>LWS:</b> Port Link State Write Strobe (LWS) RW. Default = 0. When this bit is set to 1 on a write reference to this register, this flag enables writes to the PLS field. When 0, write data in PLS field is ignored. Reads to this bit return 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 15:14     | 0h<br>RW         | <b>PIC:</b> Port Indicator Control (PIC) RWS. Default = 0. Writing to these bits has no effect if the Port Indicators (PIND) bit in the HCCPARAMS register is a 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 13:10     | 0h<br>RW         | <b>PORTSPEED:</b> Port Speed (Port Speed) ROS. Default = 0. This field identifies the speed of the connected USB Device. This field is only relevant if a device is connected (CCS = 1) in all other cases this field shall indicate Undefined Speed. (more information in the XHCI specification)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 9         | 1h<br>RW         | <b>PP:</b> Port Power (PP) RWS. Default = 1. This flag reflects a port's logical, power control state. Because host controllers can implement different methods of port power switching, this flag may or may not represent whether (VBus) power is actually applied to the port. When PP equals a '0' the port is nonfunctional and shall not report attaches, detaches, or Port Link State (PLS) changes. However, the port shall report over-current conditions when PP = 0 if PPC = 0. After modifying PP, software shall read PP and confirm that it is reached its target state before modifying it again, undefined behavior may occur if this procedure is not followed. 0 = This port is in the Powered-off state. 1 = This port is not in the Powered-off state. If the Port Power Control (PPC) flag in the HCCPARAMS register is '1', then xHC has port power control switches and this bit represents the current setting of the switch ('0' = off, '1' = on). If the Port Power Control (PPC) flag in the HCCPARAMS register is '0', then xHC does not have port power control switches and each port is hard wired to power, and not affected by this bit. When an over-current condition is detected on a powered port, the xHC shall transition the PP bit in each affected port from a 1 to 0 (removing power from the port). Note: If this is an SSIC Port, then the DSP Disconnect process is initiated by '1' to '0' transition of PP. Refer to section 5.1.2 in the SSIC Spec for more information. Refer to section 4.19.4 for more information. |
| 8:5       | 5h<br>RW         | <b>PLS:</b> Port Link State (PLS) RWS. Default = RxDetect (5). This field is used to power manage the port and reflects its current link state. When the port is in the Enabled state, system software may set the link U state by writing this field. System software may also write this field to force a Disabled to Disconnected state transition of the port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 4         | 0h<br>RW         | <b>PR:</b> Port Reset (PR) RW1S. Default = 0. 1 = Port Reset signaling is asserted. 0 = Port is not in Reset. When software writes a 1 to this bit generating a 0 to 1 transition, the bus reset sequence is initiated; USB2 protocol ports shall execute the bus reset sequence as defined in the USB2 Spec. USB3 protocol ports shall execute the Hot Reset sequence as defined in the USB3 Spec. PR remains set until reset signaling is completed by the root hub. Note that software shall write a 1 to this flag to transition a USB2 port from the Polling state to the Enabled state. Refer to sections 4.15.2.3 and 4.19.1.1. This flag is 0 if PP is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 3         | 0h<br>RW         | <b>OCA:</b> Over-current Active (OCA) RO. Default = 0. 1 = This port currently has an over-current condition. 0 = This port does not have an over-current condition. This bit shall automatically transition from a 1 to a 0 when the over-current condition is removed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| 1         | 0h<br>RW         | <b>PED:</b> Port Enabled/Disabled (PED) RW1CS. Default = 0. 1 = Enabled. 0 = Disabled. Ports may only be enabled by the xHC. Software cannot enable a port by writing a 1 to this flag. A port may be disabled by software writing a 1 to this flag. This flag shall automatically be cleared to 0 by a disconnect event or other fault condition. Note that the bit status does not change until the port state actually changes. There may be a delay in disabling or enabling a port due to other host controller or bus events. When the port is disabled (PED = 0) downstream propagation of data is blocked on this port, except for reset. For USB2 protocol ports: When the port is in the Disabled state, software shall reset the port (PR = 1) to transition PED to 1 and the port to the Enabled state. For USB3 protocol ports: When the port is in the Polling state (after detecting an attach), the port shall automatically transition to the Enabled state and set PED to 1 upon the completion of successful link training. When the port is in the Disabled state, software shall write a 5 (RxDetect) to the PLS field to transition the port to the Disconnected state. Refer to section 4.19.1.2. PED shall automatically be cleared to 0 when PR is set to 1, and set to 1 when PR transitions from 1 to 0 after a successful reset. Refer to Port Reset (PR) bit for more information on how the PED bit is managed. Note that when software writes this bit to a 1, it shall also write a 0 to the PR bit. This flag is 0 if PP is 0. |
| 0         | 0h<br>RW         | <b>CCS:</b> Current Connect Status (CCS) ROS. Default = 0. 1 = A device is connected to the port. 0 = A device is not connected. This value reflects the current state of the port, and may not correspond directly to the event that caused the Connect Status Change (CSC) bit to be set to 1. Refer to sections 4.19.3 and 4.19.4 for more details on the Connect Status Change (CSC) assertion conditions. This flag is 0 if PP is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## 19.6.19 PORTPMSC1—Offset 424h

### Access Method

**Type:** Memory Mapped I/O Register  
(Size: 32 bits)

**PORTPMSC1:** [BAR] + 424h

**BAR Type:** PCI Configuration Register (Size: 32 bits)

**BAR Reference:** [B:0, D:22, F:0] + 10h

**Default:** 00000000h

|-----------|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31        | 0h<br>RW         | <b>WPR:</b> Warm Port Reset (WPR) RW1S/RsvdZ. Default = 0. When software writes a 1 to this bit, the Warm Reset sequence as defined in the USB3 Specification is initiated and the PR flag is set to 1. Once initiated, the PR, PRC, and WRC flags shall reflect the progress of the Warm Reset sequence. This flag shall always return 0 when read. Refer to section 4.19.5.1. This flag only applies to USB3 protocol ports. For USB2 protocol ports it shall be RsvdZ.                                                                                                                                                       |
| 30        | 0h<br>RW         | <b>DR:</b> Device Removable (DR) - RO. This flag indicates if this port has a removable device attached. 1 = Device is non-removable. 0 = Device is removable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 29:28     | 0h<br>RO         | <b>RSVD25:</b> reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 27        | 0h<br>RW         | <b>WOE:</b> Wake on Over-current Enable (WOE) RWS. Default = 0. Writing this bit to a 1 enables the port to be sensitive to over-current conditions as system wake-up eventsn. Refer to section 4.15 for operational model.                                                                                                                                                                                                                                                                                                                                                                                                     |
| 26        | 0h<br>RW         | <b>WDE:</b> Wake on Disconnect Enable (WDE) RWS. Default = 0. Writing this bit to a 1 enables the port to be sensitive to device disconnects as system wake-up eventsn. Refer to section 4.15 for operational model.                                                                                                                                                                                                                                                                                                                                                                                                            |
| 25        | 0h<br>RW         | <b>WCE:</b> Wake on Connect Enable (WCE) RWS. Default = 0. Writing this bit to a 1 enables the port to be sensitive to device connects as system wake-up events . Refer to section 4.15 for operational model.                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 24        | 0h<br>RO         | <b>RSVD24:</b> reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 23        | 0h<br>RW         | <b>CEC:</b> Port Config Error Change (CEC) RW1CS/RsvdZ. Default = 0. This flag indicates that the port failed to configure its link partner. 0 = No change. 1 = Port Config Error detected. Software shall clear this bit by writing a '1' to it. Refer to section 4.19.2 of XHCI specification for more information on change bit usage. Note: This flag is valid only for USB3 protocol ports. For USB2 protocol ports this bit shall be RsvdZ.                                                                                                                                                                               |
| 22        | 0h<br>RW         | <b>PLC:</b> Port Link State Change (PLC) RW1CS. Default = 0. This flag is set to 1 due to the PLS transitions in the XHCI specification                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 21        | 0h<br>RW         | <b>PRC:</b> Port Reset Change (PRC) RW1CS. Default = 0. This flag is set to 1 due to a '1' to '0' transition of Port Reset (PR). e.g. when any reset processing (Warm or Hot) on this port is complete. Note that this flag shall not be set to 1 if the reset processing was forced to terminate due to software clearing PP or PED to '0'. 0 = No change. 1 = Reset complete. Software shall clear this bit by writing a '1' to it. Refer to section 4.19.5. of XHCI specification. Refer to section 4.19.2 of XHCI specification. for more information on change bit usage.                                                  |
| 20        | 0h<br>RW         | <b>OCC:</b> Over-current Change (OCC) RW1CS. Default = 0. This bit shall be set to a 1 when there is a 0 to 1 or 1 to 0 transition of Over-current Active (OCA). Software shall clear this bit by writing a 1 to it. Refer to section 4.19.2 for more information on change bit usage.                                                                                                                                                                                                                                                                                                                                          |
| 19        | 0h<br>RW         | <b>WRC:</b> Warm Port Reset Change (WRC) RW1CS/RsvdZ. Default = 0. This bit is set when Warm Reset processing on this port completes. 0 = No change. 1 = Warm Reset complete. Note that this flag shall not be set to 1 if the Warm Reset processing was forced to terminate due to software clearing PP or PED to '0'. Software shall clear this bit by writing a '1' to it. Refer to section 4.19.5.1. Refer to section 4.19.2 for more information on change bit usage. This bit only applies to USB3 protocol ports. For USB2 protocol ports it shall be RsvdZ.                                                             |
| 18        | 0h<br>RW         | <b>PEC:</b> Port Enabled/Disabled Change (PEC) RW1CS. Default = 0. 1 = change in PED. 0 = No change. Note that this flag shall not be set if the PED transition was due to software setting PP to 0. Software shall clear this bit by writing a 1 to it. Refer to section 4.19.2 for more information on change bit usage. For a USB2 protocol port, this bit shall be set to 1 only when the port is disabled due to the appropriate conditions existing at the EOF2 point (refer to section 11.8.1 of the USB2 Specification for the definition of a Port Error). For a USB3 protocol port, this bit shall never be set to 1. |

| Bit Range | Default & Access | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| 17        | 0h<br>RW         | <b>CSC:</b> Connect Status Change (CSC) RW1CS. Default = 0. 1 = Change in CCS. 0 = No change. This flag indicates a change has occurred in the ports Current Connect Status (CCS) or Cold Attach Status (CAS) bits. Note that this flag shall not be set if the CCS transition was due to software setting PP to 0, or the CAS transition was due to software setting WPR to 1. The xHC sets this bit to 1 for all changes to the port device connect status, even if system software has not cleared an existing Connect Status Change. For example, the insertion status changes twice before system software has cleared the changed condition, root hub hardware will be setting an already-set bit (i.e., the bit will remain 1). Software shall clear this bit by writing a 1 to it. Refer to section 4.19.2 for more information on change bit usage.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 16        | 0h<br>RW         | <b>LWS:</b> Port Link State Write Strobe (LWS) RW. Default = 0. When this bit is set to 1 on a write reference to this register, this flag enables writes to the PLS field. When 0, write data in PLS field is ignored. Reads to this bit return 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 15:14     | 0h<br>RW         | <b>PIC:</b> Port Indicator Control (PIC) RWS. Default = 0. Writing to these bits has no effect if the Port Indicators (PIND) bit in the HCCPARAMS register is a 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 13:10     | 0h<br>RW         | <b>PORTSPEED:</b> Port Speed (Port Speed) ROS. Default = 0. This field identifies the speed of the connected USB Device. This field is only relevant if a device is connected (CCS = 1) in all other cases this field shall indicate Undefined Speed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 9         | 1h<br>RW         | <b>PP:</b> Port Power (PP) RWS. Default = 1. This flag reflects a port's logical, power control state. Because host controllers can implement different methods of port power switching, this flag may or may not represent whether (VBus) power is actually applied to the port. When PP equals a '0' the port is nonfunctional and shall not report attaches, detaches, or Port Link State (PLS) changes. However, the port shall report over-current conditions when PP = 0 if PPC = 0. After modifying PP, software shall read PP and confirm that it is reached its target state before modifying it again, undefined behavior may occur if this procedure is not followed. 0 = This port is in the Powered-off state. 1 = This port is not in the Powered-off state. If the Port Power Control (PPC) flag in the HCCPARAMS register is '1', then xHC has port power control switches and this bit represents the current setting of the switch ('0' = off, '1' = on). If the Port Power Control (PPC) flag in the HCCPARAMS register is '0', then xHC does not have port power control switches and each port is hard wired to power, and not affected by this bit. When an over-current condition is detected on a powered port, the xHC shall transition the PP bit in each affected port from a 1 to 0 (removing power from the port). Note: If this is an SSIC Port, then the DSP Disconnect process is initiated by '1' to '0' transition of PP. Refer to section 5.1.2 in the SSIC Spec for more information. Refer to section 4.19.4 for more information. |
| 8:5       | 5h<br>RW         | <b>PLS:</b> Port Link State (PLS) RWS. Default = RxDetect (5). This field is used to power manage the port and reflects its current link state. When the port is in the Enabled state, system software may set the link U state by writing this field. System software may also write this field to force a Disabled to Disconnected state transition of the port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 4         | 0h<br>RW         | <b>PR:</b> Port Reset (PR) RW1S. Default = 0. 1 = Port Reset signaling is asserted. 0 = Port is not in Reset. When software writes a 1 to this bit generating a 0 to 1 transition, the bus reset sequence is initiated; USB2 protocol ports shall execute the bus reset sequence as defined in the USB2 Spec. USB3 protocol ports shall execute the Hot Reset sequence as defined in the USB3 Spec. PR remains set until reset signaling is completed by the root hub. Note that software shall write a 1 to this flag to transition a USB2 port from the Polling state to the Enabled state. Refer to sections 4.15.2.3 and 4.19.1.1. of XHCI specification. This flag is 0 if PP is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 3         | 0h<br>RW         | <b>OCA:</b> Over-current Active (OCA) RO. Default = 0. 1 = This port currently has an over-current condition. 0 = This port does not have an over-current condition. This bit shall automatically transition from a 1 to a 0 when the over-current condition is removed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

### 19.6.35 DB 1—Offset 484h

The Doorbell Array is organized as an array of up to 256 Doorbell Registers. One 32-bit Doorbell Register is defined in the array for each Device Slot. System software utilizes the Doorbell Register to notify the xHC that it has Device Slot related work for the xHC to perform.

## Access Method

### 19.6.37 DB 3—Offset 48Ch

The Doorbell Array is organized as an array of up to 256 Doorbell Registers. One 32-bit Doorbell Register is defined in the array for each Device Slot. System software utilizes the Doorbell Register to notify the xHC that it has Device Slot related work for the xHC to perform.

#### 19.6.40 DB 6—Offset 498h

The Doorbell Array is organized as an array of up to 256 Doorbell Registers. One 32-bit Doorbell Register is defined in the array for each Device Slot. System software utilizes the Doorbell Register to notify the xHC that it has Device Slot related work for the xHC to perform.

### 19.6.50 DB 16—Offset 4C0h

The Doorbell Array is organized as an array of up to 256 Doorbell Registers. One 32-bit Doorbell Register is defined in the array for each Device Slot. System software utilizes the Doorbell Register to notify the xHC that it has Device Slot related work for the xHC to perform.

DWC_USB3_GUSB3PIPECTL_INIT[23] should be used to start receiver detection manually. This bit is valid for Downstream ports only. Delay P1P2P3 Delay P0 to P1/P2/P3 request when entering U1/U2/U3 until (DWC_USB3_GUSB3PIPECTL_INIT[21:19]*8) 8B10B error occurs, or Pipe3_RxValid drops to 0. DWC_USB3_GUSB3PIPECTL_INIT[18] must be 1 to enable this functionality. Delay PHY power change from P0 to P1/P2/P3 when link state changing from U0 to U1/U2/U3 respectively. n 1'b1: When entering U1/U2/U3, delay the transition to P1/P2/P3 until the pipe3 signals, Pipe3_RxElecIdle is 1 and pipe3_RxValid is 0 n 1'b0: When entering U1/U2/U3, transition to P1/P2/P3 without checking for Pipe3_RxElecIdle and pipe3_RxValid. Note: This bit should be set to '1' for Synopsys PHY. It is also used by third-party SS PHY. |
