

# **TDC-GPX2** 4-Channel Time-to-Digital Converter

## **General Description**

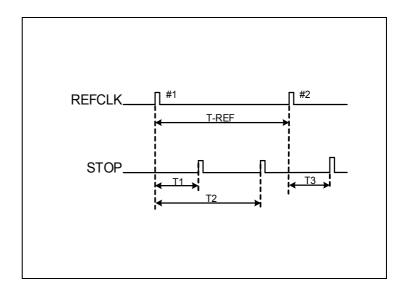

The GPX2 is a high performance time-to-digital converter (TDC) frontend device.

Highest measurement performance and highest data throughput is achieved with LVDS stop inputs and LVDS serial outputs for each channel. Current saving operation is also possible with CMOS inputs and SPI readout.

High configuration flexibility and unlimited measurement range cover many applications. They range from portable handheld laser range equipment to ambitious time-of-flight measurements of highest performance, as e.g. done in medical imaging applications.

GPX2 operates without any locked loop technologies. GPX2 calculates all stop measurements inside, proportional to the applied reference clock. Combinations of best single shot accuracy of 10ps with lowest pulse-to-pulse spacing <5ns and maximum data throughput rate of 70MSPS per stop input are possible.

Figure 1: Time Interval Measurements

Ordering Information and Content Guide appear at end of datasheet.

## Key Benefits & Features

The benefits and features of this device are listed below:

#### Figure 2: Added Value of Using TDC-GPX2

| Benefits   | Features   |
|--|--|
| • Simple data post-processing thanks to calibrated results   | <ul> <li>4 stop channels with serial <ul> <li>20ns pulse-to-pulse spacing</li> <li>Maximum 35MSPS</li> </ul> </li> <li>2 combined channels with <ul> <li>5ns pulse-to-pulse spacing</li> <li>Maximum 70MSPS</li> </ul> </li> <li>Single shot accuracy <ul> <li>20ps rms single shot resolution per channel</li> <li>10ps rms with high resolution option</li> </ul> </li> <li>Unlimited measuring range 0s to 16s</li> </ul> |
| <ul> <li>Event assignment thanks to reference clock<br/>index simplifies coincidence measurements</li> <li>Easy pulse width measurements</li> <li>High efficiency thanks high sample rate</li> </ul> | <ul> <li>Differential reference clock input 2MHz to 12.5MHz, optional with quartz</li> <li>Inputs optional with LVDS or CMOS level</li> <li>Readout with LVDS or SPI</li> <li>16-stage FIFO per channel</li> <li>Automatic calibration to reference clock (no PLL or DLL)</li> <li>SPI compatible 4-wire interface for configuration</li> </ul>  |
| <ul> <li>Compact design thanks to small package<br/>and low number of external components</li> <li>Reduced cooling thanks to low power<br/>consumption</li> </ul>                                    | <ul> <li>Supply voltage 3.3V</li> <li>Power dissipation 60mW to 450mW</li> <li>Standby current 60µA</li> <li>QFN64 (9mm x 9mm) or QFP64 (12mm x 12mm)</li> </ul>   |

## Applications

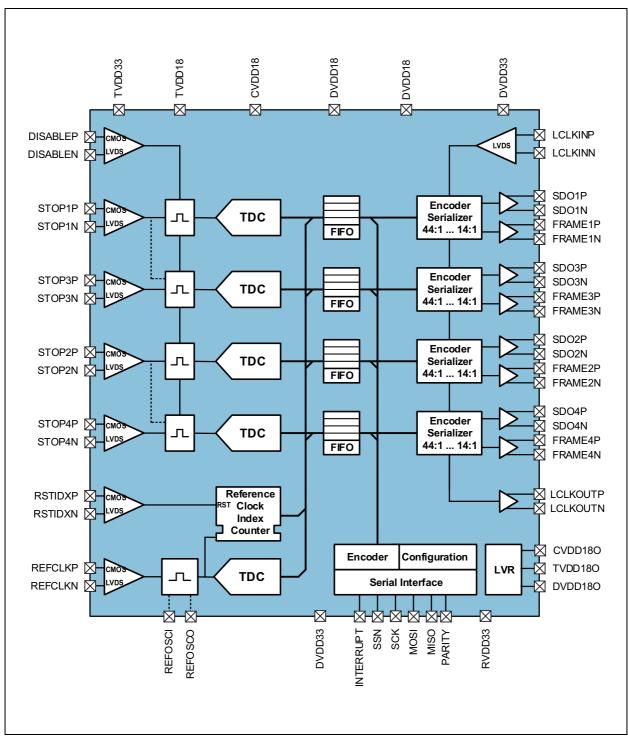

- Automated Test Equipment
- Laser Range Measurement
- Medical Imaging
- Time-of-Flight Measurement
- Particle Physics
- Lidar, Radar, Sonar

## **Block Diagram**

The functional blocks of this device are shown below:

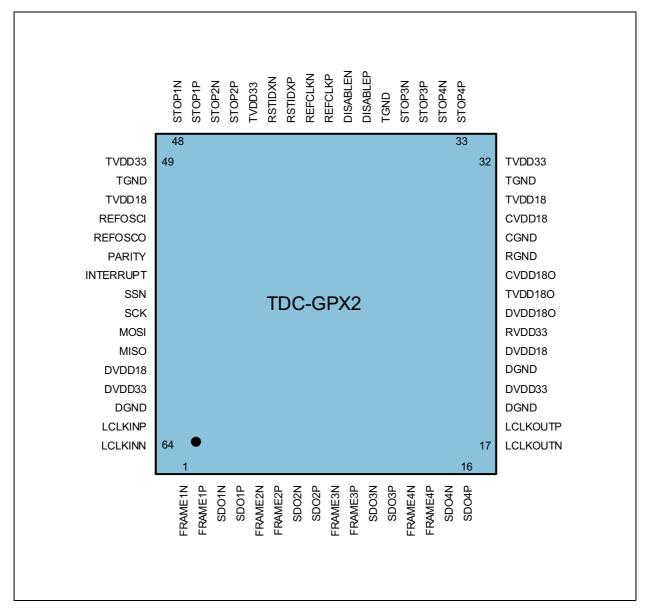

## **Pin Assignments**

The TDC-GPX2 is shipped in QFN64 or QFP64 plastic packages with the following pin assignment.

## Pin Diagram

Figure 4: Pin Diagram of TDC-GPX2

# **Pin Description**

### Figure 5: Pin Description of TDC-GPX2

| Pin No.    | Pin Name | Description                                    | Туре          | Not Used |

#### Note(s):

1. A small dot on the package indicates the pin 1. There is no need to connect the exposed pad to GND (internally not connected). Connecting it may be helpful for heat dissipation. The package is RoHS compliant and does not contain any Pb.

# Absolute Maximum Ratings

Stresses beyond the Absolute Maximum Ratings may cause permanent damages to the device. Exposure to any Absolute Maximum Rating condition for extended periods may also affect device reliability and lifetime.

Figure 6: Absolute Maximum Ratings

#### Note(s):

1. Recommended Operating Ratings indicate conditions for which the device is functional, but do not guarantee specific performance limits. Test conditions for guaranteed specification are explicitly denoted.

The following test levels apply to all following characteristics:

Figure 8: Test Levels

| Test Level | Description   |
|------------|---|
| I          | 100% production tested.   |
| II         | 100% production tested at 25 °C and guaranteed by design and characterization testing |
| III        | Parameter is guaranteed by design and characterization testing                        |
| IV         | Sample tested   |
| V          | Parameter is a typical value only.  |

# **Converter Characteristics**

General Conditions: VDD33 = 3.3V; VDD18 = 1.8V;  $T_A = 0^{\circ}C$  to  $80^{\circ}C$ .

## **Register Description**

### **Configuration Register Overview**

The configuration registers are organized in 17 addresses of one byte. All configuration registers are accessible via the SPI interface. They can be read and written individually or with an incremental access. For monitoring the chip it is possible to observe at the PARITY pin whether the sum of all set bits is even or odd.

## **Detailed Description**

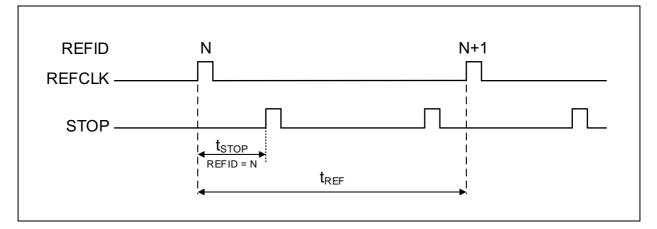

### **Time Measurements and Results**

#### **Measurements of TDC-GPX2**

The reference clock is the framework for all time measurements. The clock pulses are measured continuously by the TDC as time reference point for stop pulses and as internal reference period. The measurement of the stop events always refers to the preceding reference clock. Additionally, the reference clock is counted continuously and the actual count is assigned as reference index to a stop pulse.

- t<sub>REF</sub> is the internal TDC measurement of the reference clock period
- t<sub>STOP</sub> is the internal TDC measurement of a stop to the preceding reference clock
- **REFID** is the index of reference period where the measured stop occurred

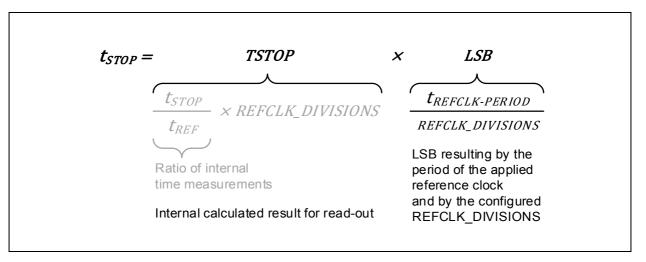

#### **Output Results**

Each stop generates a dataset which consists of two values **TSTOP** and **REFID**:

**REFID** is the reference index of the preceding reference clock pulse to TSTOP. The reference index is necessary to indicate the relationship of stop pulses which belong to different reference clock periods. The maximum length of the reference index is 24 bits.

**TSTOP** is the ratio of the internal measured times of  $t_{STOP}$  over  $t_{REF}$  scaled by the configured REFCLK\_DIVISONS. The readout result TSTOP is always less than configured REFCLK\_DIVISONS. The resulting LSB at the output interface has to be chosen much lower than the single shot resolution of GPX2. For details see chapter "Coding of Results". Suitable values are e.g. 1ps, 5ps or 10ps.

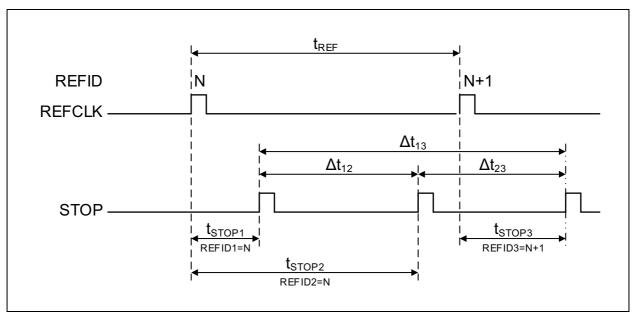

#### Figure 33: t<sub>STOP</sub> Calculation

### **Calculation of Time Differences**

The results of the GPX2 are the time intervals from stop event pulses to the preceding reference clock pulses. In many applications the time difference between stop event pulses is desired. This happens e.g. in case of a quartz as a reference clock. Depending on the application and the measurement setup, several approaches are possible to calculate the time between two stops in the connected microprocessor or FPGA.

# amu

#### **General Approach**

On the output interface, either SPI or LVDS, both data REFID and TSTOP are available. With these data it is possible to calculate time differences between stops. The maximum time difference depends on the bit width of the reference index (see also chapter "Maximum Time Differences" between stops depending on the reference index bit width)

 $\Delta t_{13} = (TSTOP3 - TSTOP1) + (REFID3 - REFID1) * REFCLK_DIVISIONS$ 

In two special cases it is not necessary to readout the REFID:

#### **Stops in the Same Reference Clock Period**

In applications where stops occur always in the same reference period (e.g. STOP1 & STOP2), it is not necessary to read out the reference index. It is sufficient just read out the stop results and to calculate the difference:

 $\Delta t_{12} = TSTOP2 - TSTOP1; REFID2 = REFID1$ 

#### Time Difference Smaller Than Reference Clock

In applications where the measured time difference  $\Delta t$  is always smaller than the reference clock period T<sub>REF</sub> but not necessarily in the same reference clock period (e.g. STOP2 & STOP3), it is often sufficient to read out just the stop results without the reference index by distinguishing positive and negative time difference:

If TSTOP3 - TSTOP2 > 0

•  $\Delta t_{23} = (TSTOP3 - TSTOP2)$ 

If TSTOP3 - TSTOP2 < 0 and  $\Delta T$  < REFCLK\_DIVISIONS

•  $\Delta t_{23} = (TSTOP3 - TSTOP2) + REFCLK_DIVISIONS$ 

## Resolution

### **RMS-Resolution Versus Effective Resolution**

The RMS resolution of a TDC is the root-mean-square-value of a set of single shot time measurements. TDC do not have an obvious full scale definition, as the time they are measuring is unlimited. Therefore, the definition of an effective resolution in number of bits likewise in ADC is not feasible.

### High Resolution

For achieving best single-shot RMS resolution, GPX2 offers a complete integrated solution. During the initial sampling the stop event is internally delayed and sampled again, after the first sample was stored in the FIFO. All samples of one stop event are averaged inside of the GPX2 and occur as one result with lower conversion noise at the output interface. With HIGH\_ RESOLUTION it is possible to configure internal 2 or 4 samples of one event. Due of the internal delay and the multiple samples the conversion latency t<sub>conv</sub> and the pulse-to-pulse spacing t<sub>PPS</sub> increase as well as the maximum FIFO\_DEPTH decreases. In order to compensate these drawbacks, it is possible to use HIGH\_RESOLUTION with both CHANNEL\_COMBINATION modes and to achieve the excellent pulse-to-pulse spacing of channel combination mode, doubled FIFO depth per stop input and higher resolution.

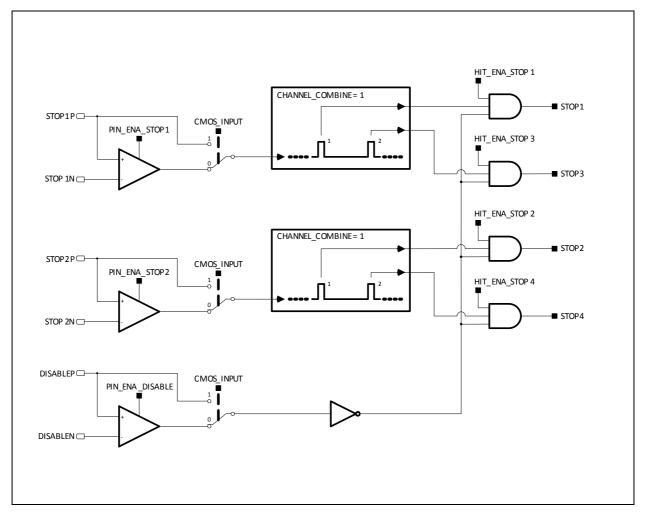

## **Combining Two Stop Channels**

## Channel Combination for Low Pulse-to-Pulse Spacing

With CHANNEL\_COMBINE set to "PULSE\_SPACING", two stop channels 1 & 3 (and 2 & 4) are connected to one input pin STOP1 (and STOP2). The stop events at the input pin are distributed alternatingly between the combined channels. Readout is indicated via FRAME or INTERRUPT pins when both channels have results in their FIFO. The advantage of combining channels lies in improved pulse-to-pulse spacing

- Excellent pulse-to-pulse spacing
- Doubled FIFO depth per stop input pin
- Higher burst storage capability
- Doubled LVDS readout rate per stop input pin
- HIGH\_RESOLUTION is applicable

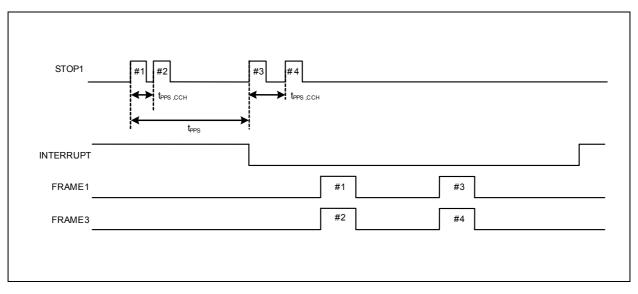

Figure 35: Channel Combination Low Pulse-to-Pulse Spacing

The outstanding low pulse-to-pulse spacing  $t_{PPS,CCH}$  is achievable only for a single pulse pair. After a pulse pair, the regular pulse-to-pulse spacing  $t_{PPS}$  must be awaited, before capturing the next pulse becomes possible. Measurements with HIGH\_RESOLUTION will increase the regular pulse-to-pulse spacing but the low pulse-to-pulse spacing  $t_{PPS,CCH}$  is not affected.

#### Figure 36: Channel Combination Low Pulse-to-Pulse Spacing

#### Note(s):

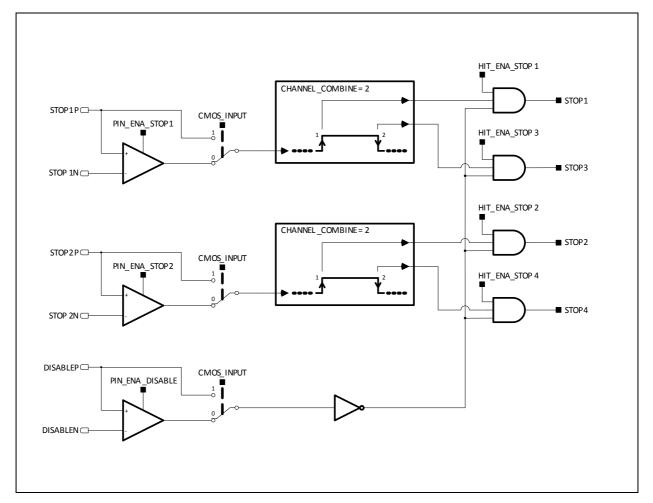

- With LVDS outputs the FRAME pins of combined channels are active together
- SPI readout of combined channel pairs is permitted only pairwise like ch1-ch3-ch1-ch3-... or ch2-ch4-ch2-ch4-.... Also incremental readout like ch1-ch2-ch3-ch4... is possible. But it is not permitted to read one channel twice like ch1-ch1-ch3-ch3-.. or ch2-ch2-ch4-ch4....

## Channel Combination for Pulse Width Measurement

With CHANNEL\_COMBINE set to "PULSE\_WIDTH" two internal stop channels 1&3 (and 2&4) are connected to one input pin STOP1 (and STOP2). The rising edges are measured by channel 1 (2), falling edges are measured by channel 3 (4). Readout starts on both channels simultaneous when a rising and falling edge was measured.

• HIGH\_RESOLUTION or COMMON\_FIFO\_READ is fully applicable

Figure 37: Channel Combination for Pulse Width Measurement

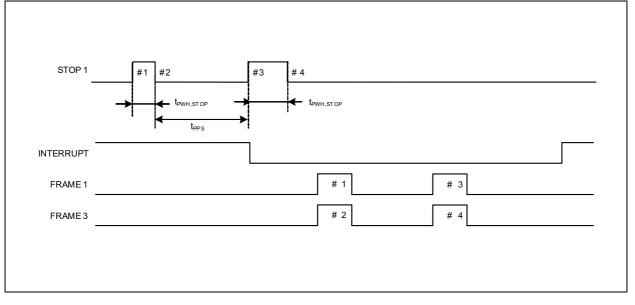

#### Note(s):

1. For internal processing reasons, after the conversion latency t<sub>PPS</sub> must be waited before capturing the next pulse. Measurements with HIGH\_RESOLUTION will increase the conversion latency but minimum pulse width t<sub>PWH\_STOP</sub> is not affected.

# amu

#### Figure 38: Channel Combination Pulse Width Measurement

#### Note(s):

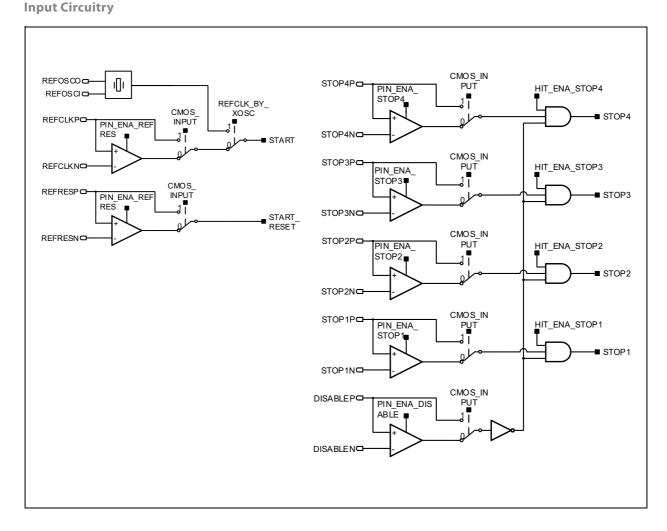

- With LVDS output the FRAME pins of combined channels are active together
- SPI readout of combined channel pairs is permitted only pairwise like ch1-ch3-ch1-ch3-... or ch2-ch4-ch2-ch4-.... Also incremental readout like ch1-ch2-ch3-ch4... is possible. But it is not permitted to read one channel twice like ch1-ch1-ch3-ch3-.. or ch2-ch2-ch4-ch4....

Figure 39:

## **Input Pins for Time Measurement**

The following diagram show the relevant input pins for the reference and the stops.

## REFCLKP/N: Reference Clock Input

The reference clock serves as universal time base. Due to internal averaging, the phase jitter of the reference clock is non-critical. The accuracy and drift of the reference clock also does not affect the proper working of GPX2 itself. But it will directly affect the quality of the time measurement results.

#### **REFOSCI/O: Quartz Driver as Reference Clock**

**Note(s):** The quartz is not mandatory for operation of GPX2.

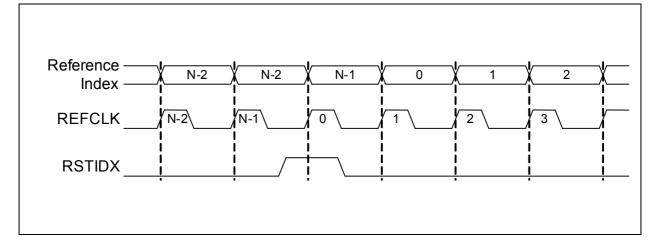

The quartz is just an optional source for the reference clock. It can be used instead of a clock signal at the reference clock pin. Therefore REFCLK pins should be disabled. With a quartz as reference clock usually the time difference between stops channels is relevant (see chapter "Calculation of Time Differences"). The use of COMMON\_FIFO\_READ and BLOCKWISE\_FIFO\_READ can help to measure and read out associated stop results together.

#### **RSTIDXP/N:** Reference Index Counter Reset

With pin RSTIDX the internal counter for the reference index is set back to zero. This option may simply the overview on the reference index in the output data stream. RSTIDX is applied synchronously to the reference clock for a single period. Therefore one reference clock cycle passes, before stop events are assigned with zero as reference index. The pin has to be activated with PIN\_ENA\_RSTIDX.

#### Figure 40: Reference Index Counter Reset

#### STOP1...STOP4P/N: Stop Channels

Inputs for the stop signals. The positive edges of the stop signals are measured versus the preceding reference clock edge.

The chip has four independent stop channels. With CHANNEL\_ COMBINE variations of this normal operation mode can be achieved.

#### DISABLE/N: Stop Disable

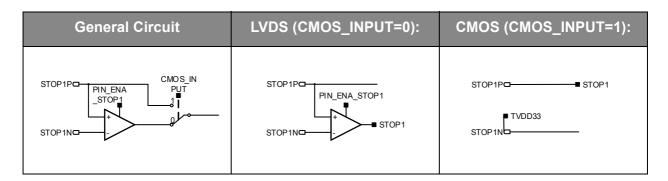

With setting stop disable pin to HIGH, the measurement on all four stops is disabled. The reference clock is not affected and internal reference measurements are continued. The DISABLE should meet the timing requirement with regards to a stop event. The pin has to be activated by configuring PIN\_ENA\_DISABLE to 1.

#### Input Levels, CMOS or LVDS

All input pins, STOP1 to STOP4, REFCLK, RSTIDX and DISABLE, can be switched in common to CMOS input levels with CMOS\_INPUT configuration. Tie the unused negative inputs to TVDD33.

Figure 41: CMOS-LVDS

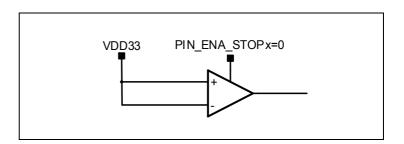

#### Termination of Differential LVDS Input Pin

Integrated termination is not provided. It is necessary to place termination resistors on the PCB near to the input pins. The default termination for LVDS signals is to have single  $100\Omega$  resistors between the differential lines.

#### **Connection of Unused LVDS Inputs**

Any kind of unused LVDS inputs (e.g. STOP1 to STOP4, REFCLK, RSTIDX, DISABLE, LCLKIN) have to be pulled up to VDD33 and disabled by setting PIN\_ENA to zero. Unused channels should also be switched off with HIT\_ENA\_STOP1...4.

Figure 42: Unused LVDS

#### Software Enable (HIT\_ENA\_STOP1...4)

Setting the configuration bits HIT\_ENA\_STOP1 to HIT\_ENA\_ STOP4 applies a software enable for stop channels 1 to 4.

#### Pin Enable (PIN\_ENA\_xxx)

The pin enable registers PIN\_ENA\_STOP1 to PIN\_ENA\_STOP4, PIN\_ENA\_REFCLK, PIN\_ENA\_RSTIDX and PIN\_ENA\_DISABLE activate the LVDS input or output drivers of the related pins. Main purpose of PIN\_ENA is cutting of current consumption of unused differential LVDS buffer to nearly zero. But also with CMOS\_INPUTs the pin need to be activated. In case of the LVDS output interface, PIN\_ENA\_STOP1 to PIN\_ENA\_STOP4 enable also the according LVDS output drivers.

## **LVDS Output Interface**

## Digital Output Interface

Each stop channel has its own serial interface with a data output SDO pin and a FRAME pin to indicate the MSB. Data output is supported on falling edges (SDR, single data read) or rising and falling edges (DDR, double data read). The operating clock is looped from LCLKIN through the chip to LCLKOUT pin. The data at SDO and FRAME pins have stable timing relation at <sub>DV,LVDS</sub> to LCLKOUT. The FRAME indicate the first 8bits of an output sequence. On the SDO pin the reference index is output first, and the stop result follows that. The bit width of both results is configurable by STOP\_DATA\_BITWIDTH and REF\_INDEX\_BITWIDTH. With careful configuration data overhead can be avoided in favor of higher conversion rates.

### **Output Setup and Configuration:**

LVDS output interface is activated configuring LVDS\_ENA\_ LVDSOUT =1. The clock at the input LCLKIN is looped through the chip to pins LCLKOUT. The phase of SDO and FRAME pins are in stable relation to LCLKOUT. The SDO and FRAME pins needed for output are activated according to the configuration of PAD\_ENA\_STOP1 to PAD\_ENA\_STOP4 and CHANNEL\_ COMBINE.

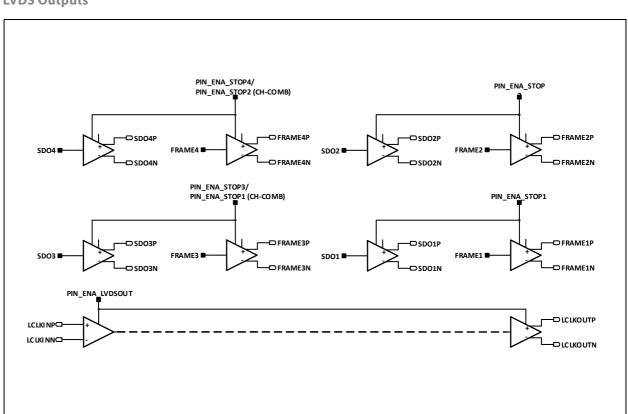

Figure 43: LVDS Outputs

#### **LVDS** Output Buffers

The LVDS output buffers SDO1 to SDO4, FRAME1 to FRAME4, and LCLKOUT are designed for 200mV voltage swing with external  $100\Omega$  termination.

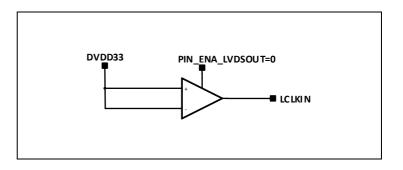

Unused LVDS output buffers can be left open.

#### **Differential LCLKIN Input**

Termination: No integrated termination resistors are provided. A termination resistor of  $100\Omega$  should be placed near the input pin.

Connection of unused LCLKIN input: LCLKIN input has to be pulled up to VDD33 and disabled by configuring PIN\_ENA\_LVDS to zero.

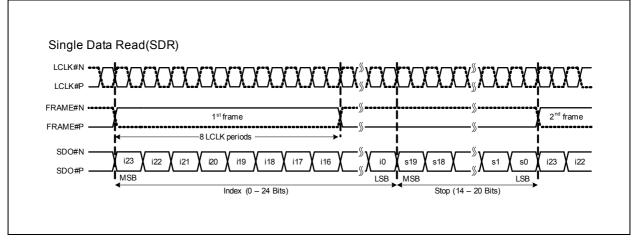

Figure 44: LCLIN Input

#### LVDS Single Data Read Output Interface (SDR)

In single data read mode (LVDS\_DOUBLE\_DATA\_RATE = 0) the data and frame bits are clocked on the falling edge of LVDS output clock LCLKOUT. The data bits are stable during the following rising edge of LCLKOUT.

#### Note(s):

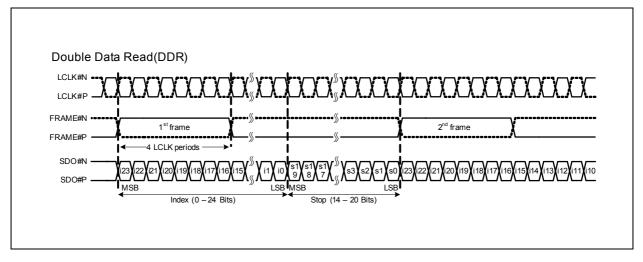

1. Bit width of the reference index and the stop result is configured by STOP\_DATA\_BITWIDTH and REF\_INDEX\_BITWIDTH

#### LVDS Double Data Read Output Interface (DDR)

With double data read mode the readout rate is doubled or alternatively the LVDS clock frequency can be halved with constant readout rate. The data and frame bits are clocked on rising and falling edges of LCLKOUT. Both bits, data and frame, are delayed by t<sub>DV,LVDS</sub> to LCLKOUT in order to grant sufficient hold time for the receiving device. With configuration parameter LVDS\_DATA\_VALID\_ADJUST the delay can be adjusted for all LVDS outputs in common.

Figure 46: LVDS Outputs

#### Note(s):

1. Bit width of the reference index and the stop result is configured by STOP\_DATA\_BITWIDTH and REF\_INDEX\_BITWIDTH

#### LVDS Output Test Pattern

Setting LVDS\_TEST\_PATTERN = 1 the interface continuously outputs the following fixed test patterns. All stop events are ignored.

Reference index = 111100001100101010101010bin (=15781034dec)

Stop result = 000010101010101110000bin (=699632dec)

Depending on the configuration of the output format width (REF\_INDEX\_BITWIDTH, STOP\_DATA\_BITWIDTH) only the corresponding lower bits of the reference index and the stop result are transmitted.

## **SPI Communication Interface**

#### General

The SPI interface is implemented to

- Reset the chip to power on state
- Write configuration registers
- Verify configuration or status registers
- Initialize and restart measurements
- Byte-wise readout of results from the read registers (see Figure 31) via SPI instead via serial LVDS outputs

The serial interface is compatible with the 4-wire SPI standard in Motorola specification:

- Clock Phase Bit = 1
- Clock Polarity Bit = 0

#### **Detailed Pin Description**

#### Pin SSN

The 'Slave Select Not' line is the HIGH-active reset for the serial interface. When set to LOW, the interface is ready for serial shift of data into or out of the device. Each access POR, INIT, READ or WRITE has to start with a positive pulse on SSN.

#### Pin SCK

The 'Serial Clock' line is the driving clock which starts at LOW level and expects HIGH active pulses.

#### Pin MOSI

The 'Master Out Slave In' line is the serial data input of the device. Data takeover is done with the falling edge of SCK. The MSB is sent first.

#### Pin MISO

At 'Master In Slave Out' line, the serial data are clocked out of the chip with the rising edge of SCK. When SSN is set to HIGH, then the data output pin MISO is in high-Z state. The MSB is sent first.

#### Pin INTERRUPT

A low level at the interrupt pin indicates to the receiving device that data are available.

#### Pin PARITY

Monitoring the chip is possible by observing the PARITY pin. It indicates whether the sum of all configuration bits is even (Parity = 0) or odd (Parity = 1).

#### **Communication Commands (Opcodes)**

#### Figure 47: Opcodes Overview

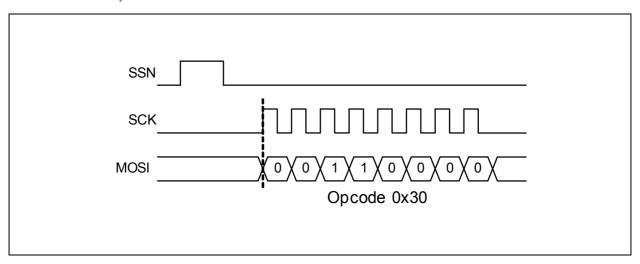

| Opcode              | HEX / BIN         | Description                                      |
|---------------------|-------------------|--|
| spiopc_power        | 0x30 = 0b00110000 | Power on reset and stop measurement              |
| spiopc_init         | 0x18 = 0b00011000 | Initializes Chip and starts measurement          |
| spiopc_write_config | 0x80 = 0b100XXXXX | Write to configuration register X=017            |
| spiopc_read_results | 0x60 = 0b011XXXXX | Read opcode for result and status register X=831 |
| spiopc_read_config  | 0x40 = 0b010XXXXX | Readout of configuration register X=017          |

#### **Detailed Command Description**

#### **Power-ON Reset**

After stabilization of all VDD33 and VDD18 the device expects the opcode spiopc\_power = 0x30 to be sent via the SPI interface for power on reset. After the last bit of the opcode the reset remains active during t<sub>HD,SSN</sub> before the device is ready for the next read or write access. After the reset, the measurement is stopped and the configuration registers are set to internal defaults of the chip.

Figure 48: Power-On Reset Opcode

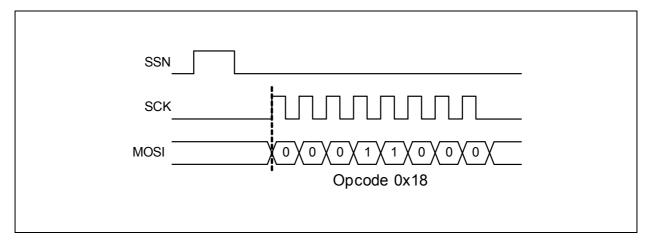

## **Initialization Reset**

After the configuration, the initialization opcode spiopc\_init=0x18 resets again the chip to power on state, but preserves the configuration and starts the measurement. The initialization reset can be send while the reference clock or stops are applied. It takes 16 pulses of the reference clock before the stop channels are opened internally. After the initialization reset the delay  $t_{POR}$  has to be waited before next communication. The initialization reset can be applied also during measurements to restart the chip, but preserves measured data in FIFOs.

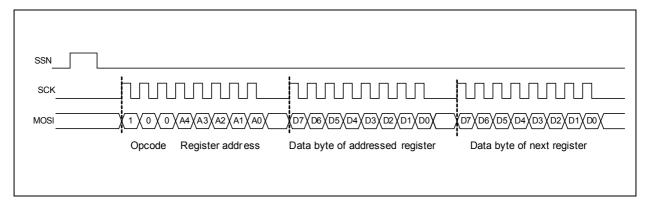

Figure 49: Initialization Reset Opcode

#### Write / Incremental Write

Write access is permitted to the configuration registers exclusively. The access starts by sending the opcode spiopc\_ write\_config = 0x80 after a positive SSN pulse. The register address is just added to spiopc\_write\_config. The data are sent after the opcode. Incremental write access to the successive registers is possible by sending the next data bytes. A complete configuration starts normally at register 0, followed by all register data bytes.

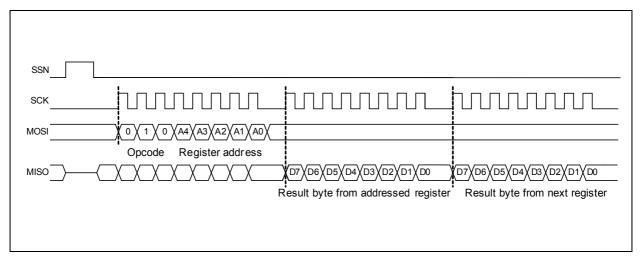

### Read / Incremental Read

The read access to registers starts by sending the opcodes spiopc\_read\_results =0x60 or spiopc\_read\_config = 0x40 after a positive SSN pulse. The register address is just added to the opcode. After the opcode the data are clocked out at the MISO line. Incremental read access to following registers is possible by continuously reading bytes. Each register is suitable as start address for incremental access.

#### Using SPI Interface for Read-Out of Stop Results

Reading results byte-wise from TDC-GPX2 e.g. by an external microcontroller is fully supported. While using the SPI interface, data read by LVDS has to be suppressed by setting PIN\_ENA\_LVDS\_OUT to zero or at least by not applying a clock at LCLKIN.

When reading an empty channel the results of REFINDEX and STOPRESULT are marked with 0xFFFFFF. Typically, the measurement rate of TDC-GPX2 is much higher than the readout rate possible with SPI. In this case using COMMON\_ FIFO\_READ and BLOCKWISE\_FIFO\_READ is helpful to get sequential results which were measured in parallel in TDC-GPX2.

REF\_INDEX\_BITWIDTH and STOP\_DATA\_BITWIDTH are not relevant for reading via SPI.

## **Coding of Results**

## Configuration of LSB by REFCLK\_DIVISIONS

The reference clock period is divided into subdivisions by REFCLK\_DIVISIONS for the definition of the LSB of the stop results at the output interface. One subdivision corresponds to the LSB and the stop results are scaled into multiples of this LSB. In order to avoid quantization artefacts of the output interface, the resulting LSB has to be much smaller than the single shot resolution of GPX2. The most convenient way is choosing an LSB of 1ps by configuring REFCLK\_DIVISIONS to the picosecond value of the reference clock period. Other LSB settings are possible as well, like LSB of 5ps or 10ps.

Figure 52: LSB Configuration

| Reference<br>Clock<br>Period | Reference<br>Clock<br>Frequency | REFCLK_DIVISIONS<br>LSB = 1ps | REFCLK_DIVISIONS<br>LSB = 5ps | REFCLK_DIVISIONS<br>LSB = 10ps |
|------------------------------|---------------------------------|-------------------------------|-------------------------------|--------------------------------|
| 500ns                        | 2MHz                            | 500000                        | 100000                        | 50000                          |
| 250ns                        | 4MHz                            | 250000                        | 50000                         | 25000                          |
| 200ns                        | 5MHz                            | 200000                        | 40000                         | 20000                          |
| 100ns                        | 10MHz                           | 100000                        | 20000                         | 10000                          |
| 50ns                         | 20MHz                           | 50000                         | 10000                         | 5000                           |

#### Note(s):

1. For LVDS output, REFCLK\_DIVISIONS must not exceed the result bit width defined by STOP\_DATA\_BITWIDTH

#### **Examples for Codes of Time Measurements Results**

Figure 53: LSB Configuration

| Readout of Sto | op Result | Resulting Stop Time with An Assumed LSB of |                         | Note         |  |                      |

| 0x0FFFFF       | 1048575   | 1048575ps                                  | See note (1)            | See note (1) | SPI:<br>Max readout with                 | 20Bit <sup>(3)</sup> |

#### Note(s):

1. Time difference exceed GPX2 specification for reference clock period

2. REFCLK\_DIVISIONS decreased by one is the highest possible readout value

3. With SPI read-out the four upper bits are unused

## Maximum Time Differences

The following table shows the maximum possible time differences between stops, depending on the reference index bit width.

### **Conversion Latency and Conversion Rate**

The conversion latency  $t_{conv}$  is the time need when an event at a stop input pin occurs until it is processed and ready for output through the interface. With LVDS instead of SPI output an additional synchronization latency to the LCLK is applied.

The conversion and synchronization latency is only applied to single events. During an output sequence of several events the conversion latency is processed in parallel during the remaining time.

#### **Converter Latency**

The conversion latency  $t_{CONV}$  is the time needed when an event at a stop input pin occurs until it is processed. Once a stop event is recognized, it has to be converted into the results of TSTOP and REFID. The basic conversion latency  $t_{CONV}$  is the same for SPI or LVDS readout. After the conversion latency has passed, the INTERRUPT pin is set to zero (if not already zero from a previous stop) and the stop result is ready for readout via the SPI interface. The conversion latency depends also on the HIGH\_RESOLUTION configuration.

# amu

#### LVDS Synchronization Latency

For both LVDS output modes, DDR+SDR, an additional synchronization latency  $t_{SYNC}$  has to be processed before the output sequence starts. With LVDS reading an additional latency  $t_{SYNC}$  for synchronization to the LCLK is applied.  $t_{SYNC}$  is counted in LVDS clock cycles and the output is indicated by setting the frame output pin.

#### **Conversion Rate**

Conversion rate is the rate where stop events can be measured. It is determined or limited by the peak input conversion rate or the read-out rate. The conversion rate of the stop events at the input can be higher or also lower than the read-out rate output interface. In any case, the FIFO will adapt a variable peak stop event rate and to the read-out rate.

#### Peak Conversion Rate

The peak input conversion rate is limited by the ability of GPX2 to sample, convert and store stop events in the FIFOs. The maximum peak conversion rate is limited minimal pulse-to-pulse-spacing t<sub>PPS</sub> of the chosen measuring mode. The number of conversions at peak conversion rate is given by the FIFO depth and to a certain extent by the read out rate of the interface.

#### **Read-Out Rate**

The maximum read-out rate is reached when the output interface (either SPI or LVDS) is continuously in use for outputting the measurement results. The configured code length (LVDS: STOP\_DATA\_BITWIDTH and REF\_INDEX\_ BITWIDTH, SPI: readout bytes) and the frequency define the readout capabilities.

#### Average Conversion Rate

The average conversion rate is determined either by the

- **Peak Input Conversion Rate:** If the read-out rate is higher than peak input conversion rate no time event is getting lost because of a full FIFO. This is typically the case when reading out with LVDS.
- **Read-Out Rate:** If read-out rate is always slower than the input conversion rate then time measurements necessarily are getting lost because the FIFO may be full. This is typically the case when reading out via SPI. In this case the configuration of BLOCKWISE\_FIFO\_READ and COMMON\_FIFO\_READ is an option even to get measured a sequence of successive stops

#### Examples for Read-Out Rate with LVDS

The conversion rate of measured stop events can be calculated by dividing the bus frequency by the number of bits, which are readout reference index and stop result. The number of bits is configured by STOP\_DATA\_BITWIDTH and REF\_INDEX\_ BITWIDTH.

#### Figure 56: Example Data Average Conversion Rate

| STOP_DATA_<br>BITWIDTH | REF_INDEX_<br>BITWIDTH | Sum<br>of Bits | LCLK   | SDR Throughput<br>Rate | DDR Throughput<br>Rate |
|------------------------|------------------------|----------------|--------|------------------------|------------------------|
| 00 (14Bit)             | 000 (0Bit)             | 14             | 300MHz | 21MSPS                 | 42MSPS                 |
| 00 (14Bit)             | 010 (4Bit)             | 18             | 300MHz | 16MSPS                 | 32MSPS                 |
| 01 (16Bit)             | 000 (0Bit)             | 16             | 300MHz | 18MSPS                 | 37MSPS                 |
| 01 (16Bit)             | 011 (8Bit)             | 24             | 300MHz | 12MSPS                 | 25MSPS                 |
| 10 (18Bit)             | 000 (0Bit)             | 18             | 200MHz | 11MSPS                 | 22MSPS                 |
| 10 (18Bit)             | 100 (16Bit)            | 32             | 200MHz | 6MSPS                  | 12MSPS                 |
| 11 (20Bit)             | 000 (0Bit)             | 20             | 100MHz | 5MSPS                  | 10MSPS                 |
| 11 (20Bit)             | 101 (24Bit)            | 44             | 100MHz | 2MSPS                  | 4MSPS                  |

#### Note(s):

1. Maximal throughput rate is only reached when the stop event rate at input is high enough

2. With CHANNEL\_COMBINE = 1 ("Pulse Distance") the throughput rate per stop input pin is doubled, as the stop events of one input pin are alternatively measured and readout by two channels.

# amu

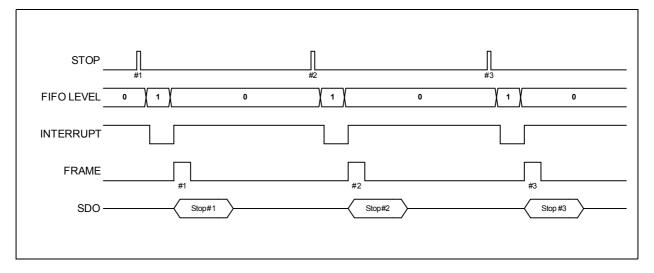

### FIFOs for Adapting Peak and Average Conversion Rate

Each channel of GPX2 has a First-In-First-Out data buffer (FIFO). Generally, GPX2 is capable of measuring the incoming stops faster than the length of an output sequence. The FIFO is capable of storing up to data of 16 stop events until the data are read out. Up to a certain degree, the FIFO prevents rejection of stop events for a short time when the input stop event rate is higher than the read-out rate. But when the input data rate is constantly higher than the read-out rate, then the FIFO gets full and stop events are rejected. After a full FIFO was read out and empty space is available for stop measurement further two stops are needed to restart the FIFO (t<sub>FIFO RESTART</sub>).

The maximum FIFO depth is 16, 8 or 4 stages, depending on the HIGH\_RESOLUTION configuration (off, 2x, 4x).

The following figures illustrate the typical dependencies between stop event rate and the read out rate. They are applicable for both SPI and LVDS readout. The INTERRUPT pin indicates that the result is available for read-out through the SPI interface. For SPI a continuous readout is assumed as long as the interrupt is on low level. For LVDS output the FRAME indicates the beginning of data output at SDO line. The interrupt goes back to HIGH when all FIFOs are empty even if output is LVDS. In the figures FIFO\_DEPTH = 4 is assumed. The FIFO LEVEL indicates the stop event buffered in the FIFO. A stop event will increase FIFO LEVEL by one, reading out will decrease the FIFO LEVEL.

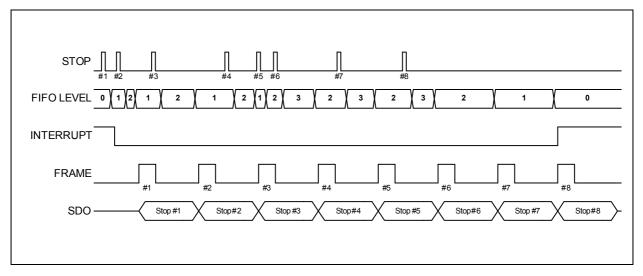

- Enough time for complete readout of first stop before the next stop event arises
- Interrupt goes back to high because the FIFO is empty after read-out
- In this example, no stop events are rejected. All stops are measured and read out

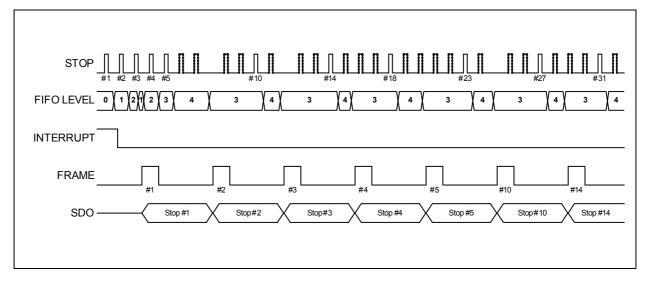

#### Figure 58:

- Stop events during read-out are stored in FIFO
- Stop events buffer up to FIFO LEVEL 3
- In this example, no stop events are rejected. All stops are measured and read out.
- Interrupt goes back to high when all data are readout and the FIFO is empty.
- Maximal FIFO\_DEPTH and HIGH\_RESOLUTION limits the peak event storage

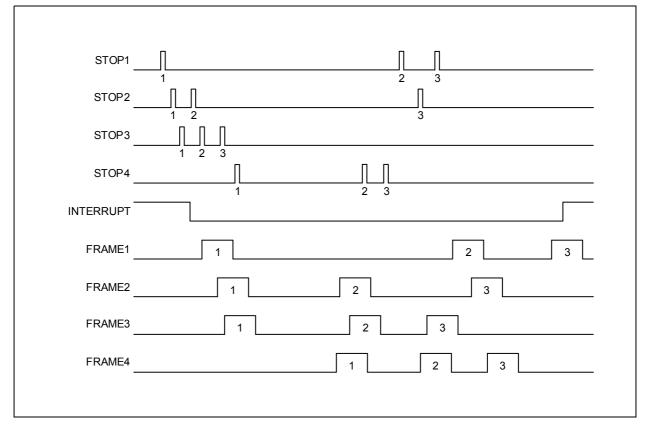

- During read-out stop events (dots) are ignored when FIFO full at FIFO LEVEL 4.
- After reading a result from a full FIFO the next two stops events (dashed) are still ignored but used to restart the FIFO
- Interrupt is always zero because the FIFO never gets empty.

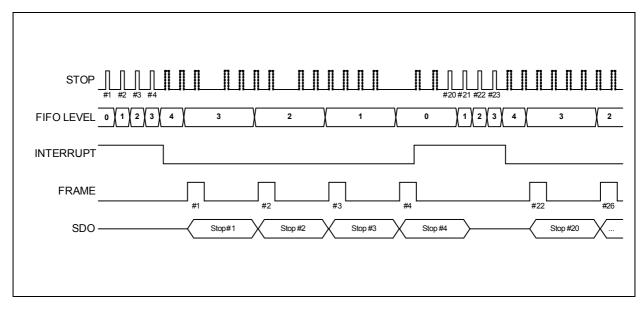

## Figure 60:

**Stops on All Four Channels** 

- All four channels are completely independent from each other (COMMON\_FIFO\_READ=0)
- In this example no stop events are rejected, because FIFOs never get full
- Interrupt remains zero as long as at least one FIFO has a valid data, interrupt gets high when all FIFO are empty

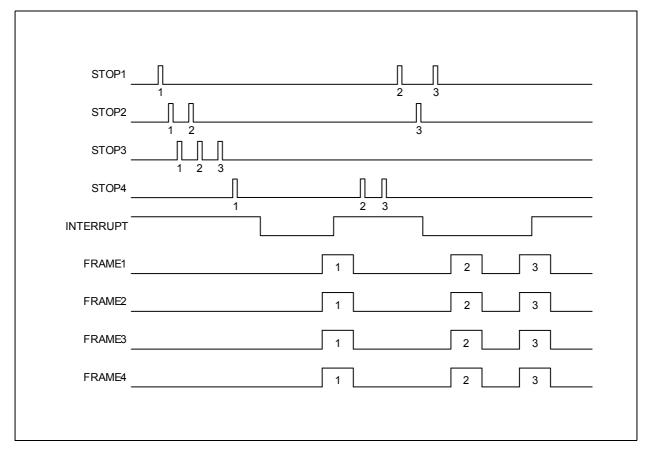

Figure 61: BLOCKWISE\_FIFO\_READ

- A block of successive stop events are measured in a block before readout
- Readout of FIFO starts not before the FIFO is full.
- During read-out stop events (dots) are ignored when FIFO full at FIFO level 4...1.
- After reading all result from the FIFO the next two stops events (dashed) are still ignored but used to restart the FIFO
- Measurement starts not before the FIFO is empty.
- COMMON\_FIFO\_READ is applicable.

#### Figure 62: COMMON\_FIFO\_READ

- All active FRAME pins are set simultaneously, as soon as all active FIFOs have value (COMMON\_FIFO\_READ = 1)
- As long as one FIFO has no valid data, no readout is done
- Interrupt doesn't fall to low before all active FIFOs have valid data
- In this example no stop events are rejected, because FIFOs never get full.
- BLOCKWISE\_FIFO\_READ is fully applicable
- SPI readout only successively of all active FIFOs (1, 2, 3, 4 ...). It is not permitted to read one channel twice (e.g 1 & 1, 2 & 2 ...)

## Schematic

The following figures show a typical circuits with power supply and line termination.

Figure 63: Schematics for LVDS Inputs and Outputs

#### Figure 64: Schematics for CMOS Inputs and SPI Communication

# amu

## **External Components**

Supply Decoupling: GPX2 provides 6 power supply domains. Careful buffering is recommended. Small decoupling capacitors (e.b 100nF) with minimal ESL and ESR help to filter external power supply noise when placed near to the power supply pins.

The optimum number of decoupling capacitors depends on the actual application.

It is recommended to use separate supplies for time-analog (TVDD33) and digital (DVDD33, RVDD33) supply pins to isolate digital switching noise from sensitive circuitry. In case only a single (digital) supply is available, it should be routed to DVDD33 and RVDD33. It can then be tapped and isolated with a resistor ( $10\Omega$ ) to TVDD33. Grounding: A single ground plane is sufficient to give optimum performance, provided the analog, digital and clock sections of the board are cleanly partitioned. Refer to the GPX2 Evaluation PCB for an example on board layout schemes.

Signal lines: Even though LVDS signalizing on input and output reduces ground bounding during its transition, the positive and negative signal path has to be well matched and their trace should be kept as short as possible. Time-analog signal path like quartz oscillator or single ended (CMOS) stop inputs must be treated as a transmission line and should have a solid ground return path with a small loop. A serial resistor ( $10\Omega$ ) in single ended (CMOS) signal lines further help to damp reflections.

## **PCB** Layout

Please refer to our GPX2-EVA-KIT

## Package Drawings & Markings

The TDC-GPX2 comes in QFN64 or QFP64 package.

## **Mechanical Data**

## QFN64

The QFN64 package has 9mm x 9mm outline. The solder pitch is 0.5mm. Package dimensions do not include mold flash, protrusions, burrs or metal smearing. All dimensions are given in millimeters.

#### **QFN64** Tray Information

JEDEC NHBG09091.510266 Rev. A 10x 26 = 260 pieces

# QFP64

The QFP64 package has 10mm x 10mm body size, with pins 12mm x 12mm outline. The solder pitch is 0.5mm. Package dimensions do not include mold flash, protrusions, burrs or metal smearing. All dimensions are given in millimeters.

## **QFP64 Tape & Reel Information**

1 reel = 250 pcs

Soldering & Storage Information Center-pad can be connected to ground or left open. Through-connections (vias) in the area between the center-pad and the pins should be avoided.

## **Ordering & Contact Information**

## RoHS Compliant & ams Green Statement

**RoHS:** The term RoHS compliant means that ams AG products fully comply with current RoHS directives. Our semiconductor products do not contain any chemicals for all 6 substance categories, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, RoHS compliant products are suitable for use in specified lead-free processes.

**ams Green (RoHS compliant and no Sb/Br):** ams Green defines that in addition to RoHS compliance, our products are free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material).

**Important Information:** The information provided in this statement represents ams AG knowledge and belief as of the date that it is provided. ams AG bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. ams AG has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. ams AG and ams AG suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

Компания «Океан Электроники» предлагает заключение долгосрочных отношений при поставках импортных электронных компонентов на взаимовыгодных условиях!

Наши преимущества:

- Поставка оригинальных импортных электронных компонентов напрямую с производств Америки, Европы и Азии, а так же с крупнейших складов мира;

- Широкая линейка поставок активных и пассивных импортных электронных компонентов (более 30 млн. наименований);

- Поставка сложных, дефицитных, либо снятых с производства позиций;
- Оперативные сроки поставки под заказ (от 5 рабочих дней);
- Экспресс доставка в любую точку России;
- Помощь Конструкторского Отдела и консультации квалифицированных инженеров;
- Техническая поддержка проекта, помощь в подборе аналогов, поставка прототипов;
- Поставка электронных компонентов под контролем ВП;
- Система менеджмента качества сертифицирована по Международному стандарту ISO 9001;

- При необходимости вся продукция военного и аэрокосмического назначения проходит испытания и сертификацию в лаборатории (по согласованию с заказчиком):

- Поставка специализированных компонентов военного и аэрокосмического уровня качества (Xilinx, Altera, Analog Devices, Intersil, Interpoint, Microsemi, Actel, Aeroflex, Peregrine, VPT, Syfer, Eurofarad, Texas Instruments, MS Kennedy, Miteq, Cobham, E2V, MA-COM, Hittite, Mini-Circuits, General Dynamics и др.);

Компания «Океан Электроники» является официальным дистрибьютором и эксклюзивным представителем в России одного из крупнейших производителей разъемов военного и аэрокосмического назначения «JONHON», а так же официальным дистрибьютором и эксклюзивным представителем в России производителя высокотехнологичных и надежных решений для передачи СВЧ сигналов «FORSTAR».

«JONHON» (основан в 1970 г.)

Разъемы специального, военного и аэрокосмического назначения:

(Применяются в военной, авиационной, аэрокосмической, морской, железнодорожной, горно- и нефтедобывающей отраслях промышленности)

«FORSTAR» (основан в 1998 г.)

ВЧ соединители, коаксиальные кабели, кабельные сборки и микроволновые компоненты:

(Применяются в телекоммуникациях гражданского и специального назначения, в средствах связи, РЛС, а так же военной, авиационной и аэрокосмической отраслях промышленности).
