

**GENERAL DESCRIPTION**

The XRT83SL38 is a fully integrated Octal (eight channel) short-haul line interface unit for T1 (1.544Mbps) 100Ω, E1 (2.048Mbps) 75Ω or 120Ω, or J1 110Ω applications.

In T1 applications, the XRT83SL38 can generate five transmit pulse shapes to meet the short-haul Digital Cross-Connect (DSX-1) template requirements. It also provides programmable transmit pulse generators for each channel that can be used for output pulse shaping allowing performance improvement over a wide variety of conditions (The arbitrary pulse generators are available in both T1 and E1 modes).

The XRT83SL38 provides both a parallel **Host** microprocessor interface as well as a **Hardware** mode for programming and control.

Both the B8ZS and HDB3 encoding and decoding functions are selectable as well as AMI. An on-chip crystal-less jitter attenuator with a 32 or 64 bit FIFO can be placed either in the receive or the transmit path with loop bandwidths of less than 3Hz. The

XRT83SL38 provides a variety of loop-back and diagnostic features as well as transmit driver short circuit detection and receive loss of signal monitoring. It supports internal impedance matching for 75Ω, 100Ω, 110Ω and 120Ω for both transmitter and receiver. In the absence of the power supply, the transmit outputs and receive inputs are tri-stated allowing for redundancy applications. The chip includes an integrated programmable clock multiplier that can synthesize T1 or E1 master clocks from a variety of external clock sources.

**APPLICATIONS**

- T1 Digital Cross-Connects (DSX-1)
- ISDN Primary Rate Interface
- CSU/DSU E1/T1/J1 Interface
- T1/E1/J1 LAN/WAN Routers
- Public switching Systems and PBX Interfaces
- T1/E1/J1 Multiplexer and Channel Banks

**Features (See Page 2)**

**FIGURE 1. BLOCK DIAGRAM OF THE XRT83SL38 T1/E1/J1 LIU (HOST MODE)**

**FIGURE 2. BLOCK DIAGRAM OF THE XRT83SL38 T1/E1/J1 LIU (HARDWARE MODE)**

**FEATURES**

- Fully integrated eight channel short-haul transceivers for E1,T1 or J1 applications
- Programmable Transmit Pulse Shaper for E1,T1 or J1 short-haul interfaces
- Five fixed transmit pulse settings for T1 short-haul applications plus a fully programmable waveform generator for transmit output pulse shaping available for both T1 and E1 modes
- Selectable receiver sensitivity from 0 to 36dB cable loss
- Receive monitor mode handles 0 to 29dB resistive attenuation along with 0 to 6dB of cable attenuation for E1 and 0 to 3dB of cable attenuation for T1 modes
- Supports 75Ω and 120Ω (E1), 100Ω (T1) and 110Ω (J1) applications
- Internal and/or external impedance matching for 75Ω, 100Ω, 110Ω and 120Ω
- Tri-State transmit output and receive input capability for redundancy applications
- Provides High Impedance for Tx and Rx during power off
- Transmit return loss meets or exceeds ETSI 300-166 standard
- On-chip digital clock recovery circuit for high input jitter tolerance
- Crystal-less digital jitter attenuator with 32-bit or 64-bit FIFO selectable either in transmit or receive path
- On-chip frequency multiplier generates T1 or E1 Master clocks from variety of external clock sources
- High receiver interference immunity
- On-chip transmit short-circuit protection and limiting, and driver fail monitor output (DMO)
- Receive loss of signal (RLOS) output
- On-chip HDB3/B8ZS/AMI encoder/decoder functions
- QRSS pattern generator and detection for testing and monitoring

- Error and Bipolar Violation Insertion and Detection
- Receiver Line Attenuation Indication Output in 1dB steps
- Network Loop-Code Detection for automatic Loop-Back Activation/Deactivation
- Transmit All Ones (TAOS) and In-Band Network Loop Up and Down code generators
- Supports Local Analog, Remote, Digital and Dual Loop-Back Modes
- Meets or exceeds T1 and E1 short-haul network access specifications in ITU G.703, G.775, G.736 and G.823; TR-TSY-000499; ANSI T1.403 and T1.408; ETSI 300-166 and AT&T Pub 62411
- Supports both **Hardware** and **Host** (parallel Microprocessor) interface for programming
- Programmable Interrupt
- Low power dissipation
- Logic inputs accept either 3.3V or 5V levels
- Single 3.3V Supply Operation
- 225 ball BGA package
- -40°C to +85°C Temperature Range

**FUNCTIONAL DESCRIPTION**

The XRT83SL38 is a fully integrated short-haul transceiver intended for T1, J1 or E1 systems. Simplified block diagrams of the chip are shown in **Figure 1, Host mode** and **Figure 2, Hardware mode**.

In T1 applications, the XRT83SL38 can generate five transmit pulse shapes to meet the short-haul Digital Cross-connect (DSX-1) template requirement. The operation and configuration of the XRT83SL38 can be controlled through a parallel microprocessor **Host** interface or **Hardware** control.

**MASTER CLOCK GENERATOR**

Using a variety of external clock sources, the on-chip frequency synthesizer generates the T1 (1.544MHz) or E1 (2.048MHz) master clocks necessary for the transmit pulse shaping and receive clock recovery circuit.

There are two master clock inputs MCLKE1 and MCLKT1. In systems where both T1 and E1 master clocks are available these clocks can be connected to the respective pins. All channels of a given XRT83SI38 must be operated at the same clock rate, either T1, E1 or J1 modes.

In systems that have only one master clock source available (E1 or T1), that clock should be connected to both MCLKE1 and MCLKT1 inputs for proper operation. T1 or E1 master clocks can be generated from 8kHz, 16kHz, 56kHz, 64kHz, 128kHz and 256kHz external clocks under the control of CLKSEL[2:0] inputs according to **Table 1**.

**NOTE:** EQC[4:0] determine the T1/E1 operating mode. See **Table 5** for details.

**FIGURE 3. TWO INPUT CLOCK SOURCE**

**FIGURE 4. ONE INPUT CLOCK SOURCE**

TABLE 1: MASTER CLOCK GENERATOR

MCLKE1 kHz	MCLKT1 kHz	CLKSEL2	CLKSEL1	CLKSEL0	MCLKRATE	MASTER CLOCK kHz
2048	2048	0	0	0	0	2048
2048	2048	0	0	0	1	1544
2048	1544	0	0	0	0	2048
1544	1544	0	0	1	1	1544
1544	1544	0	0	1	0	2048
2048	1544	0	0	1	1	1544
8	x	0	1	0	0	2048
8	x	0	1	0	1	1544
16	x	0	1	1	0	2048
16	x	0	1	1	1	1544
56	x	1	0	0	0	2048
56	x	1	0	0	1	1544
64	x	1	0	1	0	2048
64	x	1	0	1	1	1544
128	x	1	1	0	0	2048
128	x	1	1	0	1	1544
256	x	1	1	1	0	2048
256	x	1	1	1	1	1544

In **Host** mode the programming is achieved through the corresponding interface control bits, the state of the CLKSEL[2:0] control bits and the state of the MCLKRATE interface control bit.

## RECEIVER

### RECEIVER INPUT

At the receiver input, a cable attenuated AMI signal can be coupled to the receiver through a capacitor or a 1:1 transformer. The input signal is first applied to a selective equalizer for signal conditioning. The maximum equalizer gain is up to 36 dB for both T1 and E1 modes. The equalized signal is subsequently applied to a peak detector which in turn controls the equalizer settings and the data slicer. The slicer threshold for both E1 and T1 is typically set at 50% of the peak amplitude at the equalizer output. After the slicers, the digital representation of the AMI signals are applied to the clock and data recovery circuit. The recovered data subsequently goes through the jitter attenuator and decoder (if selected) for HDB3 or B8ZS decoding before being applied to the RPOS\_n/RDATA\_n and RNEG\_n/LCV\_n pins. Clock recovery is accomplished by a digital phase-locked loop (DPLL) which does not require any external components and can tolerate high levels of input jitter that meets or exceeds the ITU-G.823 and TR-TSY000499 standards.

**RECEIVE MONITOR MODE**

In applications where Monitor mode is desired, the equalizer can be configured in a gain mode which handles input signals attenuated resistively up to 29dB, along with 0 to 6dB cable attenuation for both T1 and E1 applications, refer to **Table 5** for details. This feature is available in both **Hardware** and **Host** modes.

**RECEIVER LOSS OF SIGNAL (RLOS)**

For compatibility with ITU G.775 requirements, the RLOS monitoring function is implemented using both analog and digital detection schemes. If the analog RLOS condition occurs, a digital detector is activated to count for 32 consecutive zeros in E1 (4096 bits in Extended Los mode, EXLOS = "1") or 175 consecutive zeros in T1 before RLOS is asserted. RLOS is cleared when the input signal rises +3dB (built in hysteresis) above the point at which it was declared and meets 12.5% ones density of 4 ones in a 32 bit window, with no more than 16 consecutive zeros for E1. In T1 mode, RLOS is cleared when the input signal rises +3dB (built in hysteresis) above the point at which it was declared and contains 16 ones in a 128 bit window with no more than 100 consecutive zeros in the data stream. When loss of signal occurs, RLOS register indication and register status will change. If the RLOS register enable is set high (enabled), the alarm will trigger an interrupt causing the interrupt pin (INT) to go low. Once the alarm status register has been read, it will automatically reset upon read (RUR), and the INT pin will return high.

**Analog RLOS**

**Setting the Receiver Inputs to -15dB T1/E1 Short Haul Mode**

By setting the receiver inputs to -15dB T1/E1 short haul mode, the equalizer will detect the incoming amplitude and make adjustments by adding gain up to a maximum of +15dB normalizing the T1/E1 input signal.

*NOTE: This is the only setting that refers to cable loss (frequency), not flat loss (resistive).*

Once the T1/E1 input signal has been normalized to 0dB by adding the maximum gain (+15dB), the receiver will declare RLOS if the signal is attenuated by an additional -9dB. The total cable loss at RLOS declaration is typically -24dB (-15dB + -9dB). A 3dB hysteresis was designed so that transients will not trigger the RLOS to clear. Therefore, the RLOS will typically clear at a total cable attenuation of -21dB. See **Figure 5** for a simplified diagram.

**FIGURE 5. SIMPLIFIED DIAGRAM OF -15dB T1/E1 SHORT HAUL MODE AND RLOS CONDITION**

**Setting the Receiver Inputs to -29dB T1/E1 Gain Mode**

By setting the receiver inputs to -29dB T1/E1 gain mode, the equalizer will detect the incoming amplitude and make adjustments by adding gain up to a maximum of +29dB normalizing the T1/E1 input signal.

*NOTE: This is the only setting that refers to flat loss (resistive). All other modes refer to cable loss (frequency).*

Once the T1/E1 input signal has been normalized to 0dB by adding the maximum gain (+29dB), the receiver will declare RLOS if the signal is attenuated by an additional -9dB. The total cable loss at RLOS declaration is typically -38dB (-29dB + -9dB). A 3dB hysteresis was designed so that transients will not trigger the RLOS to clear. Therefore, the RLOS will typically clear at a total flat loss of -35dB. See **Figure 6** for a simplified diagram.

**FIGURE 6. SIMPLIFIED DIAGRAM OF -29dB T1/E1 GAIN MODE AND RLOS CONDITION**

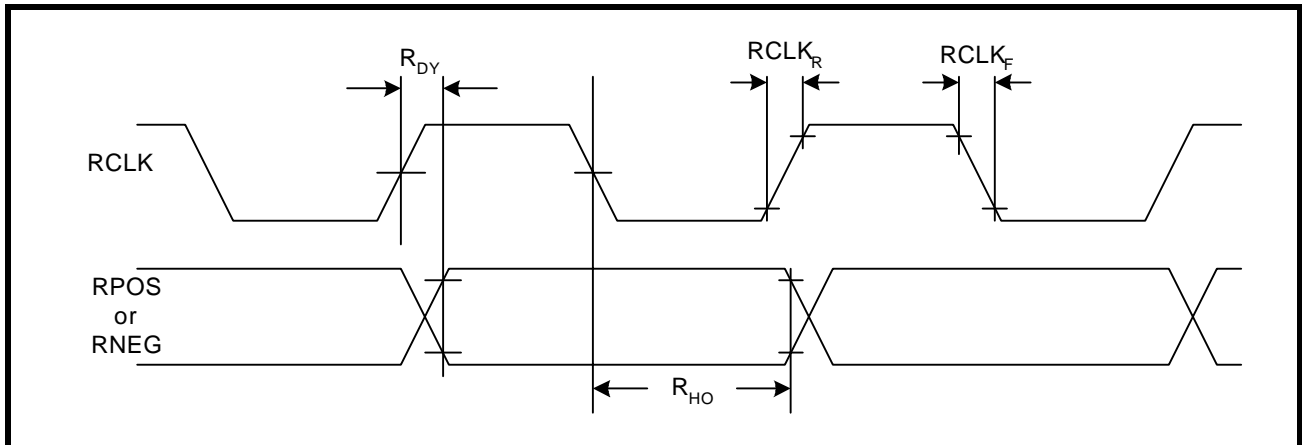

**RECEIVE HDB3/B8ZS DECODER**

The Decoder function is available in both **Hardware** and **Host** modes on a per channel basis by controlling the TNEG\_n/CODES\_n pin or the CODES\_n interface bit. The decoder function is only active in single-rail Mode. When selected, receive data in this mode will be decoded according to HDB3 rules for E1 and B8ZS for T1 systems. Bipolar violations that do not conform to the coding scheme will be reported as Line Code Violation at the RNEG\_n/LCV\_n pin of each channel. The length of the LCV pulse is one RCLK cycle for each code violation. In E1mode only, an excessive number of zeros in the receive data stream is also reported as an error at the same output pin. If AMI decoding is selected in single rail mode, every bipolar violation in the receive data stream will be reported as an error at the RNEG\_n/LCV\_n pin.

**RECOVERED CLOCK (RCLK) SAMPLING EDGE**

This feature is available in both **Hardware** and **Host** modes on a global basis. In **Host** mode, the sampling edge of RCLK output can be changed through the interface control bit RCLKE. If a "1" is written in the RCLKE interface bit, receive data output at RPOS\_n/RDATA\_n and RNEG\_n/LCV\_n are updated on the falling edge of RCLK for all eight channels. Writing a "0" to the RCLKE register, updates the receive data on the rising edge of RCLK. In **Hardware** mode the same feature is available under the control of the RCLKE pin.

**FIGURE 7. RECEIVE CLOCK AND OUTPUT DATA TIMING**

**JITTER ATTENUATOR**

To reduce phase and frequency jitter in the recovered clock, the jitter attenuator can be placed in the receive signal path. The jitter attenuator uses a data FIFO (First In First Out) with a programmable depth that can vary between 2x32 and 2x64. The jitter attenuator can also be placed in the transmit signal path or disabled altogether depending upon system requirements. The jitter attenuator, other than using the master clock as reference, requires no external components. With the jitter attenuator selected, the typical throughput delay from input to output is 16 bits for 32 bit FIFO size or 32 bits for 64 bit FIFO size. When the read and write pointers of the FIFO in the jitter attenuator are within two bits of over-flowing or under-flowing, the bandwidth of the jitter attenuator is widened to track the short term input jitter, thereby avoiding data corruption. When this situation occurs, the jitter attenuator will not attenuate input jitter until the read/write pointer's position is outside the two bits window. Under normal condition, the jitter transfer characteristic meets the narrow bandwidth requirement as specified in ITU- G.736, ITU- I.431 and AT&T Pub 62411 standards.

In T1 mode the Jitter Attenuator Bandwidth is always set to 3Hz. In E1 mode, the bandwidth can be reduced through the JABW control signal. When JABW is set "High" the bandwidth of the jitter attenuator is reduced from 10Hz to 1.5Hz. Under this condition the FIFO length is automatically set to 64 bits and the 32 bits FIFO length will not be available in this mode. Jitter attenuator controls are available on a per channel basis in the **Host** mode and on a global basis in the **Hardware** mode.

**GAPPED CLOCK (JA MUST BE ENABLED IN THE TRANSMIT PATH)**

The XRT83SL38 LIU is ideal for multiplexer or mapper applications where the network data crosses multiple timing domains. As the higher data rates are de-multiplexed down to T1 or E1 data, stuffing bits are removed which can leave gaps in the incoming data stream. If the jitter attenuator is enabled in the transmit path, the 32-Bit or 64-Bit FIFO is used to smooth the gapped clock into a steady T1 or E1 output. The maximum gap width of the 8-Channel LIU is shown in **Table 2**.

**TABLE 2: MAXIMUM GAP WIDTH FOR MULTIPLEXER/MAPPER APPLICATIONS**

FIFO DEPTH	MAXIMUM GAP WIDTH
32-Bit	20 UI
64-Bit	50 UI

**NOTE:** *If the LIU is used in a loop timing system, the jitter attenuator should be enabled in the receive path.*

**ARBITRARY PULSE GENERATOR FOR T1 AND E1**

The arbitrary pulse generator divides the pulse into eight individual segments. Each segment is set by a 7-Bit binary word by programming the appropriate channel register. This allows the system designer to set the overshoot, amplitude, and undershoot for a unique line build out. The MSB (bit 7) is a sign-bit. If the sign-bit is set to “1”, the segment will move in a positive direction relative to a flat line (zero) condition. If this sign-bit is set to “0”, the segment will move in a negative direction relative to a flat line condition. A pulse with numbered segments is shown in **Figure 8**.

**FIGURE 8. ARBITRARY PULSE SEGMENT ASSIGNMENT**

By default, the arbitrary segments are programmed to 0x00h. The transmitter outputs will result in an all zero pattern to the line. For E1 arbitrary mode, see global register 0xC0h.

**TRANSMITTER****DIGITAL DATA FORMAT**

Both the transmitter and receiver can be configured to operate in dual or single-rail data formats. This feature is available under both **Hardware** and **Host** control modes, on a global basis. The dual or single-rail data format is determined by the state of the SR/DR pin in **Hardware** mode or SR/DR interface bit in the **Host** mode. In single-rail mode, transmit clock and NRZ data are applied to TCLK\_n and TPOS\_n/TDATA\_n pins respectively. In single-rail and **Hardware** mode the TNEG\_n/CODES\_n input can be used as the CODES function. With TNEG\_n/CODES\_n tied “Low”, HDB3 or B8ZS encoding and decoding are enabled for E1 and T1 modes respectively. With TNEG\_n/CODES\_n tied “High”, the AMI coding scheme is selected. In both dual or single-rail modes of operations, the transmitter converts digital input data to a bipolar format before being transmitted to the line.

**TRANSMIT CLOCK (TCLK) SAMPLING EDGE**

Serial transmit data at TPOS\_n/TDATA\_n and TNEG\_n/CODES\_n are clocked into the XRT83SL38 under the synchronization of TCLK\_n. With a “0” written to the TCLKE interface bit, or by pulling the TCLKE pin “Low”, input data is sampled on the falling edge of TCLK\_n. The sampling edge is inverted with a “1” written to TCLKE interface bit, or by connecting the TCLKE pin “High”.

**FIGURE 9. TRANSMIT CLOCK AND INPUT DATA TIMING**

**TRANSMIT HDB3/B8ZS ENCODER**

The Encoder function is available in both **Hardware** and **Host** modes on a per channel basis by controlling the TNEG\_n/CODES\_n pin or CODES interface bit. The encoder is only available in single-rail mode. In E1 mode and with HDB3 encoding selected, any sequence with four or more consecutive zeros in the input serial data from TPOS\_n/TDATA\_n, will be removed and replaced with 000V or B00V, where “B” indicates a pulse conforming with the bipolar rule and “V” representing a pulse violating the rule. An example of HDB3 Encoding is shown in **Table 3**. In a T1 system, an input data sequence with eight or more consecutive zeros will be removed and replaced using the B8ZS encoding rule. An example of Bipolar with 8 Zero Substitution (B8ZS) encoding scheme is shown in **Table 4**. Writing a “1” into the CODES\_n interface bit or connecting the TNEG\_n/CODES\_n pin to a “High” level selects the AMI coding for both E1 or T1 systems.

**TABLE 3: EXAMPLES OF HDB3 ENCODING**

	NUMBER OF PULSE BEFORE NEXT 4 ZEROS	NEXT 4 BITS
Input		0000
HDB3 (case1)	odd	000V

AMI Output	+	000+ -0- +
<b>CASE 2</b>		
Input	-	00000000
B8ZS		000VB0VB
AMI Output	-	000- +0+ -

**DRIVER FAILURE MONITOR (DMO)**

The driver monitor circuit is used to detect transmit driver failure by monitoring the activities at TTIP and TRING outputs. Driver failure may be caused by a short circuit in the primary transformer or system problems at the transmit input. If the transmitter of a channel has no output for more than 128 clock cycles, the corresponding DMO pin goes “High” and remains “High” until a valid transmit pulse is detected. In **Host** mode, the failure of the transmit channel is reported in the corresponding interface bit. If the DMOIE bit is also enabled, any transition on the DMO interface bit will generate an interrupt. The driver failure monitor is supported in both **Hardware** and **Host** modes on a per channel basis.

**TRANSMIT PULSE SHAPER & LINE BUILD OUT (LBO) CIRCUIT**

The transmit pulse shaper circuit uses the high speed clock from the Master timing generator to control the shape and width of the transmitted pulse. The internal high-speed timing generator eliminates the need for a tightly controlled transmit clock (TCLK) duty cycle. With the jitter attenuator not in the transmit path, the transmit output will generate no more than 0.025Unit Interval (UI) peak-to-peak jitter. In **Hardware** mode, the state of the A[4:0]/EQC[4:0] pins determine the transmit pulse shape for all eight channels. In **Host** mode transmit pulse shape can be controlled on a per channel basis using the interface bits EQC[4:0]. The chip supports five fixed transmit pulse settings for T1 Short-haul applications plus a fully programmable waveform generator for arbitrary transmit output pulse shapes (The arbitrary pulse generators are available for both T1 and E1). The choice of the transmit pulse shape and LBO under the control of the interface bits are summarized in **Table 5**. For CSU LBO transmit pulse design information, refer to ANSI T1.403-1993 Network-to-Customer Installation specification, Annex-E.

**NOTE:** EQC[4:0] determine the T1/E1 operating mode of the XRT83SL38. When EQC4 = “1” and EQC3 = “1”, the XRT83SL38 is in the E1 mode, otherwise it is in the T1/J1 mode. For details on how to enable the E1 arbitrary mode, see global register 0xC0h.

### TRANSMIT AND RECEIVE TERMINATIONS

The XRT83SL38 is a versatile LIU that can be programmed to use one Bill of Materials (BOM) for worldwide applications for T1, J1 and E1. For specific applications the internal terminations can be disabled to allow the use of existing components and/or designs.

#### RECEIVER (CHANNELS 0 - 7)

##### INTERNAL RECEIVE TERMINATION MODE

In **Hardware** mode, RXTSEL (Pin 83) can be tied “High” to select internal termination mode for all receive channels or tied “Low” to select external termination mode. Individual channel control can only be done in **Host** mode. By default the XRT83SL38 is set for external termination mode at power up or at **Hardware** reset.

**TABLE 6: RECEIVE TERMINATION CONTROL**

RXTSEL	RX TERMINATION
0	EXTERNAL
1	INTERNAL

In **Host** mode, bit 7 in the appropriate channel register, (Table 20, “Microprocessor Register #1, Bit Description,” on page 52), is set “High” to select the internal termination mode for that specific receive channel.

**FIGURE 10. SIMPLIFIED DIAGRAM FOR THE INTERNAL RECEIVE AND TRANSMIT TERMINATION MODE**

**XRT83SL38****OCTAL T1/E1/J1 SH TRANSCEIVER WITH CLOCK RECOVERY AND JITTER ATTENUATOR    *REV. 1.0.2***

If the internal termination mode (RXTSEL = "1") is selected, the effective impedance for E1, T1 or J1 can be achieved either with an internal resistor or a combination of internal and external resistors as shown in **Table 7**.

**NOTE:** In **Hardware** mode, pins RXRES[1:0] control all channels.

**TABLE 7: RECEIVE TERMINATIONS**

RXTSEL	TERSEL1	TERSEL0	RXRES1	RXRES0	R <sub>ext</sub>	R <sub>int</sub>	MODE

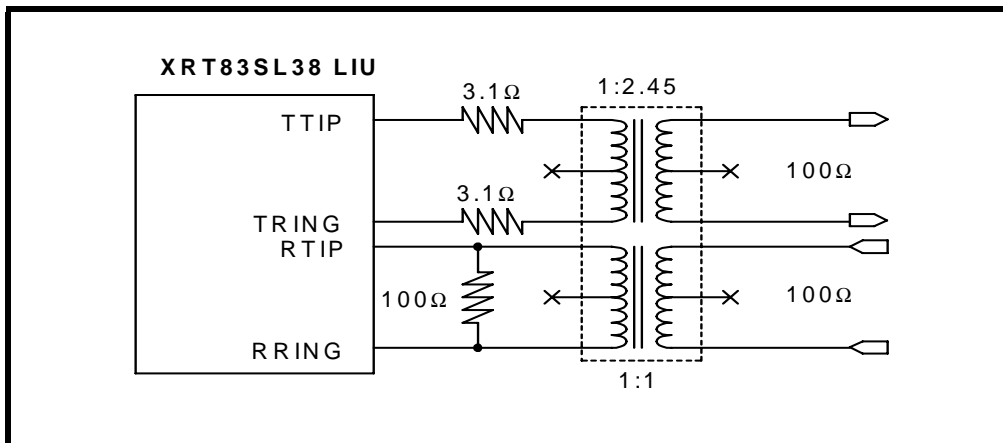

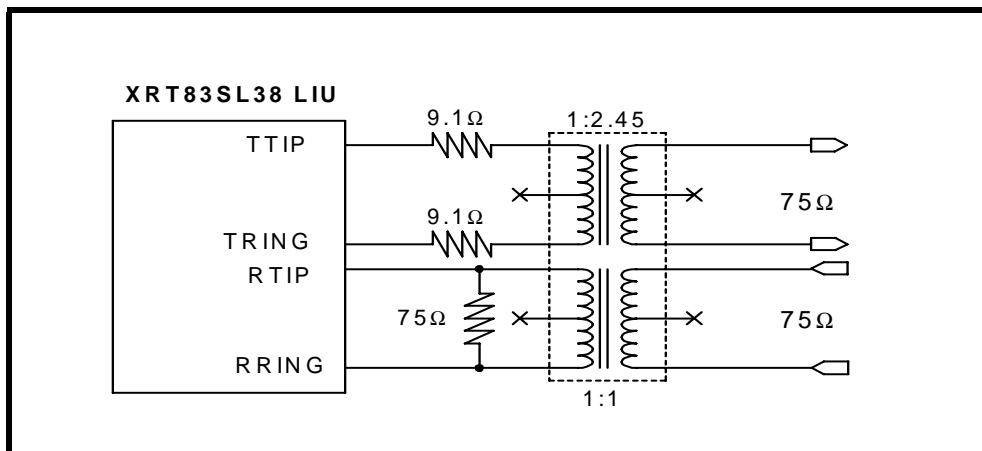

FIGURE 12. SIMPLIFIED DIAGRAM FOR E1 IN EXTERNAL TERMINATION MODE (RXTSEL= 0)

**TRANSMITTER (CHANNELS 0 - 7)**

**TRANSMIT TERMINATION MODE**

In **Hardware** mode, TXTSEL (Pin 84) can be tied “High” to select internal termination mode for all transmit channels or tied “Low” for external termination. Individual channel control can be done only in **Host** mode. In **Host** mode, bit 6 in the appropriate register for a given channel is set “High” to select the internal termination mode for that specific transmit channel, see Table 20, “Microprocessor Register #1, Bit Description,” on page 52.

TABLE 8: TRANSMIT TERMINATION CONTROL

TXTSEL	TX TERMINATION	Tx TRANSFORMER RATIO
0	EXTERNAL	1:2.45
1	INTERNAL	1:2

For internal termination, the transformer turns ratio is always 1:2. In internal mode, no external resistors are used. An external capacitor of 0.68μF is used for proper operation of the internal termination circuitry, see Figure 10.

TABLE 9: TERMINATION SELECT CONTROL

TERSEL1	TERSEL0	TERMINATION
0	0	100Ω
0	1	110Ω
1	0	75Ω
1	1	120Ω

**EXTERNAL TRANSMIT TERMINATION MODE**

By default the XRT83SL38 is set for external termination mode at power up or at **Hardware** reset.

When external transmit termination mode is selected, the internal termination circuitry is disabled. The value of the external resistors is chosen for a specific application according to the turns ratio selected by TRATIO (Pin 127) in **Hardware** mode or bit 0 in the appropriate register for a specific channel in **Host** mode, see Table 10 and Table 22, “Microprocessor Register #3, Bit Description,” on page 56. Figure 11 is a simplified block

diagram for T1 (100Ω) in the external termination mode. **Figure 12** is a simplified block diagram for E1 (75Ω) in the external termination mode.

### REDUNDANCY APPLICATIONS

Telecommunication system design requires signal integrity and reliability. When a T1/E1 primary line card has a failure, it must be swapped with a backup line card while maintaining connectivity to a backplane without losing data. System designers can achieve this by implementing common redundancy schemes with the XRT83SL38 Line Interface Unit (LIU). The XRT83SL38 offers features that are tailored to redundancy applications while reducing the number of components and providing system designers with solid reference designs. These features allow system designers to implement redundancy applications that ensure reliability. The Internal Impedance mode eliminates the need for external relays when using the 1:1 and 1+1 redundancy schemes.

**PROGRAMMING CONSIDERATIONS**

In many applications switching the control of the transmitter outputs and the receiver line impedance to **hardware** control will provide faster transmitter ON/OFF switching.

In **Host** Mode, there are two bits in register 130 (82H) that control the transmitter outputs and the Rx line impedance select, TXONCNTL (Bit 7) and TERCNTL (Bit 6).

Setting bit-7 (TXONCNTL) to a “1” transfers the control of the Transmit On/Off function to the TXON\_n **Hardware** control pins. (Pins 90 through 93 and pins 169 through 172).

Setting bit-6 (TERCNTL) to a “1” transfers the control of the Rx line impedance select (RXTSEL) to the RXTSEL **Hardware** control pin (pin 83).

Either mode works well with redundancy applications. The user can determine which mode has the fastest switching time for a unique application.

**TYPICAL REDUNDANCY SCHEMES**

- ·1:1 One backup card for every primary card (Facility Protection)
- ·1+1 One backup card for every primary card (Line Protection)
- ·N+1 One backup card for N primary cards

**1:1 REDUNDANCY**

A 1:1 facility protection redundancy scheme has one backup card for every primary card. When using 1:1 redundancy, the backup card has its transmitters tri-stated and its receivers in high impedance. This eliminates the need for external relays and provides one bill of materials for all interface modes of operation. The transmit and receive sections of the LIU device are described separately.

**1+1 REDUNDANCY**

A 1+1 line protection redundancy scheme has one backup card for every primary card, and the receivers on the backup card are monitoring the receiver inputs. Therefore, the receivers on both cards need to be active. The transmit outputs require no external resistors. The transmit and receive sections of the LIU device are described separately.

**TRANSMIT 1:1 & 1+1 REDUNDANCY**

For 1:1 and 1+1 redundancy, the transmitters on the primary and backup card should be programmed for Internal Impedance mode. The transmitters on the backup card should be tri-stated. Select the appropriate impedance for the desired mode of operation, T1/E1/J1. A 0.68uF capacitor is used in series with TTIP for blocking DC bias. See **Figure 13** for a simplified block diagram of the transmit section for 1:1 and 1+1 redundancy scheme.

**NOTE:** For simplification, the over voltage protection circuitry was omitted.

**FIGURE 13. SIMPLIFIED BLOCK DIAGRAM OF THE TRANSMIT SECTION FOR 1:1 & 1+1 REDUNDANCY**

**RECEIVE 1:1 & 1+1 REDUNDANCY**

For 1:1 and 1+1 redundancy, the receivers on the primary card should be programmed for Internal Impedance mode. The receivers on the backup card should be programmed for External Impedance mode. Since there is no external resistor in the circuit, the receivers on the backup card will be high impedance. This key design feature eliminates the need for relays and provides one bill of materials for all interface modes of operation. Select the impedance for the desired mode of operation, T1/E1/J1. To swap the primary card, set the backup card to Internal Impedance mode, then the primary card to External Impedance mode. See **Figure 14** for a simplified block diagram of the receive section for a 1:1 and 1+1 redundancy scheme.

**NOTE:** For simplification, the over voltage protection circuitry was omitted.

**FIGURE 14. SIMPLIFIED BLOCK DIAGRAM - RECEIVE SECTION FOR 1:1 AND 1+1 REDUNDANCY**

**N+1 REDUNDANCY**

N+1 redundancy has one backup card for N primary cards. Due to impedance mismatch and signal contention, external relays are necessary when using this redundancy scheme. The advantage of relays is that they create complete isolation between the primary cards and the backup card. This allows all transmitters and receivers on the primary cards to be configured in internal impedance mode, providing one bill of materials for all interface modes of operation. The transmit and receive sections of the XRT83SL38 are described separately.

**TRANSMIT**

For N+1 redundancy, the transmitters on all cards should be programmed for internal impedance mode providing one bill of materials for T1/E1/J1. The transmitters on the backup card do not have to be tri-stated. To swap the primary card, close the desired relays, and tri-state the transmitters on the failed primary card. A 0.68µF capacitor is used in series with TTIP for blocking DC bias. See Figure 15 for a simplified block diagram of the transmit section for an N+1 redundancy scheme.

**NOTE:** For simplification, the over voltage protection circuitry was omitted.

**FIGURE 15. SIMPLIFIED BLOCK DIAGRAM - TRANSMIT SECTION FOR N+1 REDUNDANCY**

**RECEIVE**

For N+1 redundancy, the receivers on the primary cards should be programmed for internal impedance mode. The receivers on the backup card should be programmed for external impedance mode. Since there is no external resistor in the circuit, the receivers on the backup card will be high impedance. Select the impedance for the desired mode of operation, T1/E1/J1. To swap the primary card, set the backup card to internal impedance mode, then the primary card to external impedance mode. See **Figure 16**. for a simplified block diagram of the receive section for a N+1 redundancy scheme.

**NOTE:** For simplification, the over voltage protection circuitry was omitted.

**FIGURE 16. SIMPLIFIED BLOCK DIAGRAM - RECEIVE SECTION FOR N+1 REDUNDANCY**

**PATTERN TRANSMIT AND DETECT FUNCTION**

Several test and diagnostic patterns can be generated and detected by the chip. In **Hardware** mode each channel can be independently programmed to transmit an All Ones pattern by applying a “High” level to the corresponding TAOS\_n pin. In **Host** mode, the three interface bits TXTEST[2:0] control the pattern generation and detection independently for each channel according to **Table 12**.

**TABLE 12: PATTERN TRANSMISSION CONTROL**

TXTEST2	TXTEST1	TXTEST0	TEST PATTERN
0	x	x	None
1	0	0	TDQRSS
1	0	1	TAOS
1	1	0	TLUC
1	1	1	TLDC

**TRANSMIT ALL ONES (TAOS)**

This feature is available in both **Hardware** and **Host** modes. With the TAOS\_n pin connected to a “High” level or when interface bits TXTEST2=“1”, TXTEST1=“0” and TXTEST0=“1” the transmitter ignores input from TPOS\_n/TDATA\_n and TNEG\_n/CODES\_n pins and sends a continuous AMI encoded all “Ones” signal to the line, using TCLK\_n clock as the reference. In addition, when the **Hardware** pin and interface bit ATAOS is activated, the chip will automatically transmit the All “Ones” data from any channel that detects an RLOS condition. This feature is not available on a per channel basis. TCLK\_n must NOT be tied “Low”.

**NETWORK LOOP CODE DETECTION AND TRANSMISSION**

This feature is available in **Host** mode only. When the interface bits TXTEST2=“1”, TXTEST1=“1” and TXTEST0=“0” the chip is enabled to transmit the “00001” Network Loop-Up Code from the selected channel requesting a Loop-Back condition from the remote terminal. Simultaneously setting the interface bits NLCDE1=“0” and NLCDE0=“1” enables the Network Loop-Up code detection in the receiver. If the “00001” Network Loop-Up code is detected in the receive data for longer than 5 seconds, the NLCD bit in the interface register is set indicating that the remote terminal has activated remote Loop-Back and the chip is receiving its own transmitted data. When the interface bits TXTEST2=“1”, TXTEST1=“1” and TXTEST0=“1” the chip is enabled to transmit the Network Loop-Down Code (TLDC) “001” from the selected channel requesting the remote terminal the removal of the Loop-Back condition.

In the **Host** mode each channel is capable of monitoring the contents of the receive data for the presence of Loop-Up or Loop-Down code from the remote terminal. In the **Host** mode the two interface bits NLCDE[1:0] control the Loop-Code detection independently for each channel according to **Table 13**.

**TABLE 13: LOOP-CODE DETECTION CONTROL**

NLCDE1	NLCDE0	CONDITION
0	0	Disable Loop-Code Detection
0	1	Detect Loop-Up Code in Receive Data
1	0	Detect Loop-Down Code in Receive Data
1	1	Automatic Loop-Code detection and Remote Loop-Back Activation

Setting the interface bits to NLCDE1=“0” and NLCDE0=“1” activates the detection of the Loop-Up code in the receive data. If the “00001” Network Loop-Up code is detected in the receive data for longer than 5 seconds, the NLCD interface bit is set to “1” and stays in this state for as long as the receiver continues to receive the

Network Loop-Up Code. In this mode if the NLCD interrupt is enabled, the chip will initiate an interrupt on every transition of NLCD. The host has the option to ignore the request from the remote terminal, or to respond to the request and manually activate Remote Loop-Back. The host can subsequently activate the detection of the Loop-Down Code by setting NLCDE1="1" and NLCDE0="0". In this case, receiving the "001" Loop-Down Code for longer than 5 seconds will set the NLCD bit to "1" and if the NLCD interrupt is enabled, the chip will initiate an interrupt on every transition of NLCD. The host can respond to the request from the remote terminal and remove Loop-Back condition. In the manual Network Loop-Up (NLCDE1="0" and NLCDE0="1") and Loop-Down (NLCDE1="1" and NLCDE0="0") Code detection modes, the NLCD interface bit will be set to "1" upon receiving the corresponding code in excess of 5 seconds in the receive data. The chip will initiate an interrupt any time the status of the NLCD bit changes and the Network Loop-code interrupt is enabled.

In the **Host** mode, setting the interface bits NLCDE1="1" and NLCDE0="1" enables the automatic Loop-Code detection and Remote Loop-Back activation mode if, TXTEST[2:0] is NOT equal to "110". As this mode is initiated, the state of the NLCD interface bit is reset to "0" and the chip is programmed to monitor the receive input data for the Loop-Up Code. If the "00001" Network Loop-Up Code is detected in the receive data for longer than 5 seconds in addition to the NLCD bit in the interface register being set, Remote Loop-Back is automatically activated. The chip stays in remote Loop-Back even if it stops receiving the "00001" pattern. After the chip detects the Loop-Up code, sets the NLCD bit and enters Remote Loop-Back, it automatically starts monitoring the receive data for the Loop-Down code. In this mode however, the NLCD bit stays set even if the receiver stops receiving the Loop-Up code, which is an indication to the host that the Remote Loop-Back is still in effect. Remote Loop-Back is removed if the chip detects the "001" Loop-Down code for longer than 5 seconds. Detecting the "001" code also results in resetting the NLCD interface bit and initiating an interrupt. The Remote Loop-Back can also be removed by taking the chip out of the Automatic detection mode by programming it to operate in a different state. The chip will not respond to remote Loop-Back request if Local Analog Loop-Back is activated locally. When programmed in Automatic detection mode the NLCD interface bit stays "High" for the whole time the Remote Loop-Back is activated and initiates an interrupt any time the status of the NLCD bit changes provided the Network Loop-code interrupt is enabled.

#### **TRANSMIT AND DETECT QUASI-RANDOM SIGNAL SOURCE (TDQRSS)**

Each channel of XRT83SL38 includes a QRSS pattern generation and detection block for diagnostic purposes that can be activated only in the **Host** mode by setting the interface bits TXTEST2="1", TXTEST1="0" and TXTEST0="0". For T1 systems, the QRSS pattern is a  $2^{20}-1$  pseudo-random bit sequence (PRBS) with no more than 14 consecutive zeros. For E1 systems, the QRSS pattern is  $2^{15}-1$  PRBS with an inverted output. With QRSS and Analog Local Loop-Back enabled simultaneously, and by monitoring the status of the QRPD interface bit, all main functional blocks within the transceiver can be verified.

When the receiver achieves QRSS synchronization with fewer than 4 errors in a 128 bits window, QRPD changes from "Low" to "High". After pattern synchronization, any bit error will cause QRPD to go "Low" for one clock cycle. If the QRPDIE bit is enabled, any transition on the QRPD bit will generate an interrupt.

With TDQRSS activated, a bit error can be inserted in the transmitted QRSS pattern by transitioning the INSBER interface bit from "0" to "1". Bipolar violation can also be inserted either in the QRSS pattern, or input data when operating in the single-rail mode by transitioning the INSBPV interface bit from "0" to "1". The state of INSBER and INSBPV bits are sampled on the rising edge of the TCLK\_n. To insure the insertion of the bit error or bipolar violation, a "0" should be written in these bit locations before writing a "1".

**LOOP-BACK MODES**

The XRT83SL38 supports several Loop-Back modes under both **Hardware** and **Host** control. In **Hardware** mode the two LOOP[1:0] pins control the Loop-Back functions for each channel independently according to Table 14.

**TABLE 14: LOOP-BACK CONTROL IN HARDWARE MODE**

LOOP1	LOOP0	LOOP-BACK MODE
0	0	None
0	1	Analog
1	0	Remote
1	1	Digital

In **Host** mode the Loop-Back functions are controlled by the three LOOP[2:0] interface bits. Each channel can be programmed independently according to Table 15.

**TABLE 15: LOOP-BACK CONTROL IN HOST MODE**

LOOP2	LOOP1	LOOP0	LOOP-BACK MODE
0	X	X	None
1	0	0	Dual
1	0	1	Analog
1	1	0	Remote
1	1	1	Digital

**LOCAL ANALOG LOOP-BACK (ALOOP)**

With Local Analog Loop-Back activated, the transmit data at TTIP and TRING are looped-back to the analog input of the receiver. External inputs at RTIP/RRING in this mode are ignored while valid transmit data continues to be sent to the line. Local Analog Loop-Back exercises most of the functional blocks of the XRT83SL38 including the jitter attenuator which can be selected in either the transmit or receive paths. Local Analog Loop-Back is shown in **Figure 17**.

**FIGURE 17. LOCAL ANALOG LOOP-BACK SIGNAL FLOW**

In this mode, the jitter attenuator (if selected) can be placed in the transmit or receive path.

**REMOTE LOOP-BACK (RLOOP)**

With Remote Loop-Back activated, receive data after the jitter attenuator (if selected in the receive path) is looped back to the transmit path using RCLK as transmit timing. In this mode transmit clock and data are ignored, while RCLK and receive data will continue to be available at their respective output pins. Remote Loop-Back with jitter attenuator selected in the receive path is shown in **Figure 18**.

**FIGURE 18. REMOTE LOOP-BACK MODE WITH JITTER ATTENUATOR SELECTED IN RECEIVE PATH**

In the Remote Loop-Back mode if the jitter attenuator is selected in the transmit path, the receive data from the Clock and Data Recovery block is looped back to the transmit path and is applied to the jitter attenuator using RCLK as transmit timing. In this mode the transmit clock and data are also ignored, while RCLK and received data will continue to be available at their respective output pins. Remote Loop-Back with the jitter attenuator selected in the transmit path is shown in **Figure 19**.

**FIGURE 19. REMOTE LOOP-BACK MODE WITH JITTER ATTENUATOR SELECTED IN TRANSMIT PATH**

**DIGITAL LOOP-BACK (DLOOP)**

Digital Loop-Back or Local Loop-Back allows the transmit clock and data to be looped back to the corresponding receiver output pins through the encoder/decoder and jitter attenuator. In this mode, receive data and clock are ignored, but the transmit data will be sent to the line uninterrupted. This loop back feature allows users to configure the line interface as a pure jitter attenuator. The Digital Loop-Back signal flow is shown in **Figure 20**.

**FIGURE 20. DIGITAL LOOP-BACK MODE WITH JITTER ATTENUATOR SELECTED IN TRANSMIT PATH**

**DUAL LOOP-BACK**

Figure 21 depicts the data flow in dual-loopback. In this mode, selecting the jitter attenuator in the transmit path will have the same result as placing the jitter attenuator in the receive path. In dual Loop-Back mode the recovered clock and data from the line are looped back through the transmitter to the TTIP and TRING without passing through the jitter attenuator. The transmit clock and data are looped back through the jitter attenuator to the RCLK and RPOS/RDATA and RNEG pins.

**FIGURE 21. SIGNAL FLOW IN DUAL LOOP-BACK MODE**

## MICROPROCESSOR PARALLEL INTERFACE

XRT83SL38 is equipped with a microprocessor interface for easy device configuration. The parallel port of the XRT83SL38 is compatible with both Intel and Motorola address and data buses. The XRT83SL38 has an 8-bit address A[7:0] input and 8-bit bi-directional data bus D[7:0]. The signals required for a generic microprocessor to access the internal registers are described in **Table 16**.

TABLE 16: MICROPROCESSOR INTERFACE SIGNAL DESCRIPTION

D[7:0]	<b>Data Input (Output):</b> 8 bits bi-directional Read/Write data bus for register access.															
A[7:0]	<b>Address Input:</b> 8 bit address to select internal register location.															
$\mu$ PTS1 $\mu$ PTS2	<b>Microprocessor Type Select:</b> <table border="1" style="margin-left: 40px;"> <thead> <tr> <th><math>\mu</math>PTS2</th> <th><math>\mu</math>PTS1</th> <th><math>\mu</math>P Type</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>68HC11, 8051, 80C188 (async.)</td> </tr> <tr> <td>0</td> <td>1</td> <td>Motorola 68K (async.)</td> </tr> <tr> <td>1</td> <td>0</td> <td>Intel x86 (sync.)</td> </tr> <tr> <td>1</td> <td>1</td> <td>Intel i960, Motorola 860 (sync.)</td> </tr> </tbody> </table>	$\mu$ PTS2	$\mu$ PTS1	$\mu$ P Type	0	0	68HC11, 8051, 80C188 (async.)	0	1	Motorola 68K (async.)	1	0	Intel x86 (sync.)	1	1	Intel i960, Motorola 860 (sync.)
$\mu$ PTS2	$\mu$ PTS1	$\mu$ P Type														
0	0	68HC11, 8051, 80C188 (async.)														
0	1	Motorola 68K (async.)														
1	0	Intel x86 (sync.)														
1	1	Intel i960, Motorola 860 (sync.)														
$\mu$ PCLK	<b>Microprocessor Clock Input:</b> Input clock for synchronous microprocessor operation. Maximum clock speed is 54MHz. This pin is internally pulled "Low" for asynchronous microprocessor operation when no clock is present.															
ALE_AS	<b>Address Latch Input (Address Strobe):</b> -Intel bus timing, the address inputs are latched into the internal register on the falling edge of ALE. -Motorola bus timing, the address inputs are latched into the internal register on the falling edge of AS.															
CS	<b>Chip Select Input:</b> This signal must be "Low" in order to access the parallel port.															
RD_DS	<b>Read Input (Data Strobe):</b> -Intel bus timing, a "Low" pulse on RD selects a read operation when CS pin is "Low". -Motorola bus timing, a "Low" pulse on DS indicates a read or write operation when CS pin is "Low".															
WR_R/W	<b>Write Input (Read/Write):</b> -Intel bus timing, a "Low" pulse on WR selects a write operation when CS pin is "Low". -Motorola bus timing, a "High" pulse on R/W selects a read operation and a "Low" pulse on R/W selects a write operation when CS pin is "Low".															
RDY_DTACK	<b>Ready Output (Data Transfer Acknowledge Output):</b> -Intel bus timing, RDY is asserted "High" to indicate the XRT83SL38 has completed a read or write operation. -Motorola bus timing, DTACK is asserted "Low" to indicate the XRT83SL38 has completed a read or write operation.															
INT	<b>Interrupt Output:</b> This pin is asserted "Low" to indicate an interrupt caused by an alarm condition in the device status registers. The activation of this pin can be blocked by setting the GIE bit to "0" in the Command Control register.															

### MICROPROCESSOR REGISTER TABLES

The microprocessor interface consists of 256 addressable locations. Each channel uses 16 dedicated 8 byte registers for independent programming and control. There are four additional registers for global control of all channels and two registers for device identification and revision numbers. The remaining registers are for factory test and future expansion. The control register map and the function of the individual bits are summarized in **Table 17** and **Table 18** respectively.

**TABLE 17: MICROPROCESSOR REGISTER ADDRESS**

REGISTER NUMBER	REGISTER ADDRESS		FUNCTION
	HEX	BINARY

D5	CODES_n	<p><b>Encoding and Decoding Select:</b> Writing a "0" to this bits selects HDB3 or B8ZS encoding and decoding for channel number n. Writing "1" selects an AMI coding scheme. This bit is only active when single rail mode is selected.</p>	R/W	0															

**TABLE 22: MICROPROCESSOR REGISTER #3, BIT DESCRIPTION**

D4	RXRES1_n	<p><b>Receive External Resistor Control Pin 1:</b> In Host mode, this bit along with the RXRES0_n bit selects the value of the external Receive fixed resistor according to the following table;</p> <table border="1"> <thead> <tr> <th>RXRES1_n</th> <th>RXRES0_n</th> <th>Required Fixed External RX Resistor</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>No external Fixed Resistor</td> </tr> <tr> <td>0</td> <td>1</td> <td>240Ω</td> </tr> <tr> <td>1</td> <td>0</td> <td>210Ω</td> </tr> <tr> <td>1</td> <td>1</td> <td>150Ω</td> </tr> </tbody> </table>	RXRES1_n	RXRES0_n	Required Fixed External RX Resistor	0	0	No external Fixed Resistor	0	1	240Ω	1	0	210Ω	1	1	150Ω	R/W	0
			RXRES1_n	RXRES0_n	Required Fixed External RX Resistor														
			0	0	No external Fixed Resistor														
			0	1	240Ω														
			1	0	210Ω														
			1	1	150Ω														
D3	RXRES0_n	<p><b>Receive External Resistor Control Pin 0:</b> For function of this bit see description of D4 the RXRES1_n bit.</p>	R/W	0															
D2	INSBPV_n	<p><b>Insert Bipolar Violation:</b> When this bit transitions from “0” to “1”, a bipolar violation is inserted in the transmitted data stream of the selected channel number n. Bipolar violation can be inserted either in the QRSS pattern, or input data when operating in single-rail mode. The state of this bit is sampled on the rising edge of the respective TCLK_n.</p> <p><b>NOTE:</b> To ensure the insertion of a bipolar violation, a “0” should be written in this bit location before writing a “1”.</p>	R/W	0															
D1	INSBER_n	<p><b>Insert Bit Error:</b> With TDQRSS enabled, when this bit transitions from “0” to “1”, a bit error will be inserted in the transmitted QRSS pattern of the selected channel number n. The state of this bit is sampled on the rising edge of the respective TCLK_n.</p> <p><b>NOTE:</b> To ensure the insertion of bit error, a “0” should be written in this bit location before writing a “1”.</p>	R/W	0															
D0	TRATIO_n	<p><b>Transformer Ratio Select:</b> In the external termination mode, writing a “1” to this bit selects a transformer ratio of 1:2 for the transmitter. Writing a “0” sets the transmitter transformer ratio to 1:2.45. In the internal termination mode the transmitter transformer ratio is permanently set to 1:2 and the state of this bit has no effect.</p>	R/W	0

01110101	CHANNEL_7			
D7	Reserved		RO	0
D6	DMO_n	<b>Driver Monitor Output:</b> This bit is set to a “1” to indicate transmit driver failure is detected. The value of this bit is based on the current status of DMO for the corresponding channel. If the DMOIE bit is enabled, any transition on this bit will generate an Interrupt.	RO	0
D5	FLS_n	<b>FIFO Limit Status:</b> This bit is set to a “1” to indicate that the jitter attenuator read/write FIFO pointers are within +/- 3 bits. If the FLSIE bit is enabled, any transition on this bit will generate an Interrupt.	RO	0
D4	LCV_n	<b>Line Code Violation:</b> This bit is set to a “1” to indicate that the receiver of channel n is currently detecting a Line Code Violation or an excessive number of zeros in the B8ZS or HDB3 modes. If the LCVIE bit is enabled, any transition on this bit will generate an Interrupt.	RO	0

TABLE 24: MICROPROCESSOR REGISTER #5, BIT DESCRIPTION

D3	NLCD_n	<p><b>Network Loop-Code Detection:</b></p> <p>This bit operates differently in the Manual or the Automatic Network Loop-Code detection modes.</p> <p>In the <b>Manual Loop-Code detection mode</b>, (NLCDE1 = "0" and NLCDE0 = "1" or NLCDE1 = "1" and NLCDE0 = "0") this bit gets set to "1" as soon as the Loop-Up ("00001") or Loop-Down ("001") code is detected in the receive data for longer than 5 seconds. The NLCD bit stays in the "1" state for as long as the chip detects the presence of the Loop-code in the receive data and it is reset to "0" as soon as it stops receiving it. In this mode, if the NLCD interrupt is enabled, the chip will initiate an interrupt on every transition of the NLCD.</p> <p><b>When the Automatic Loop-code detection mode</b>, (NLCDE1 = "1" and NLCDE0 = "1") is initiated, the state of the NLCD interface bit is reset to "0" and the chip is programmed to monitor the receive input data for the Loop-Up code. This bit is set to a "1" to indicate that the Network Loop Code is detected for more than 5 seconds. Simultaneously the Remote Loop-Back condition is automatically activated and the chip is programmed to monitor the receive data for the Network Loop Down code. The NLCD bit stays in the "1" state for as long as the Remote Loop-Back condition is in effect even if the chip stops receiving the Loop-Up code. Remote Loop-Back is removed if the chip detects the "001" pattern for longer than 5 seconds in the receive data. Detecting the "001" pattern also results in resetting the NLCD interface bit and initiating an interrupt provided the NLCD interrupt enable bit is active.</p> <p><b>When programmed in Automatic detection mode</b>, the NLCD interface bit stays "High" for the entire time the Remote Loop-Back is active and initiate an interrupt anytime the status of the NLCD bit changes. In this mode, the Host can monitor the state of the NLCD bit to determine if the Remote Loop-Back is activated.</p>	RO	0
D2	AISD_n	<p><b>Alarm Indication Signal Detect:</b> This bit is set to a "1" to indicate All Ones Signal is detected by the receiver. The value of this bit is based on the current status of Alarm Indication Signal detector of channel n. If the AISDIE bit is enabled, any transition on this bit will generate an Interrupt.</p>	RO	0
D1	RLOS_n	<p><b>Receive Loss of Signal:</b> This bit is set to a "1" to indicate that the receive input signal is lost. The value of this bit is based on the current status of the receive input signal of channel n. If the RLOSIE bit is enabled, any transition on this bit will generate an Interrupt.</p>	RO	0
D0	QRPD_n	<p><b>Quasi-random Pattern Detection:</b> This bit is set to a "1" to indicate the receiver is currently in synchronization with QRSS pattern. The value of this bit is based on the current status of Quasi-random pattern detector of channel n. If the QRPDIE bit is enabled, any transition on this bit will generate an Interrupt.</p>	RO	0

The arbitrary pulse is divided into eight time segments whose combined duration is equal to one period of MCLK.</p> <p>This 7 bit number represents the amplitude of the nth channel's arbitrary pulse during the eighth time segment. B6S8_n-B0S8_n is in signed magnitude format with B6S8_n as the sign bit and B0S8_n as the least significant bit (LSB).</p>	R/W	0

**TABLE 35: MICROPROCESSOR REGISTER #128, BIT DESCRIPTION**

REGISTER ADDRESS 10000000	NAME	FUNCTION	REGISTER TYPE	RESET VALUE
BIT #				
D7	SR/DR	<b>Single-rail/Dual-rail Select:</b> Writing a "1" to this bit configures all 8 channels in the XRT83SL38 to operate in the Single-rail mode. Writing a "0" configures the XRT83SL38 to operate in Dual-rail mode.	R/W	0
D6	ATAOS	<b>Automatic Transmit All Ones Upon RLOS:</b> Writing a "1" to this bit enables the automatic transmission of All "Ones" data to the line for the channel that detects an RLOS condition. Writing a "0" disables this feature.	R/W	0
D5	RCLKE	<b>Receive Clock Edge:</b> Writing a "1" to this bit selects receive output data of all channels to be updated on the negative edge of RCLK. Writing a "0" selects data to be updated on the positive edge of RCLK.	R/W	0
D4	TCLKE	<b>Transmit Clock Edge:</b> Writing a "0" to this bit selects transmit data at TPOS_n/TDATA_n and TNEG_n/CODES_n of all channels to be sampled on the falling edge of TCLK_n. Writing a "1" selects the rising edge of the TCLK_n for sampling.	R/W	0
D3	DATAP	<b>DATA Polarity:</b> Writing a "0" to this bit selects transmit input and receive output data of all channels to be active "High". Writing a "1" selects an active "Low" state.	R/W	0
D2	Reserved			0
D1	GIE	<b>Global Interrupt Enable:</b> Writing a "1" to this bit globally enables interrupt generation for all channels. Writing a "0" disables interrupt generation.	R/W	0
D0	SRESET	<b>Software Reset <math>\mu</math>P Registers:</b> Writing a "1" to this bit longer than 10 $\mu$ s initiates a device reset through the microprocessor interface. All internal circuits are placed in the reset state with this bit set to a "1" except the microprocessor register bits.	R/W	0

## CLOCK SELECT REGISTER

The input clock source is used to generate all the necessary clock references internally to the LIU. The microprocessor timing is derived from a PLL output which is chosen by programming the Clock Select Bits and the Master Clock Rate in register 0x81h. Therefore, if the clock selection bits or the MCLRATE bit are being programmed, the frequency of the PLL output will be adjusted accordingly. During this adjustment, it is important to "Not" write to any other bit location within the same register while selecting the input/output clock frequency. For best results, register 0x81h can be broken down into two sub-registers with the MSB being bits D[7:3] and the LSB being bits D[2:0] as shown in **Figure 22**. Note: Bit D[7] is a reserved bit.

**FIGURE 22. REGISTER 0X81H SUB REGISTERS**

Programming Examples:

Example 1: Changing bits D[7:3]

If bits D[7:3] are the only values within the register that will change in a WRITE process, the microprocessor only needs to initiate ONE write operation.

Example 2: Changing bits D[2:0]

If bits D[2:0] are the only values within the register that will change in a WRITE process, the microprocessor only needs to initiate ONE write operation.

Example 3: Changing bits within the MSB and LSB

In this scenario, one must initiate TWO write operations such that the MSB and LSB do not change within ONE write cycle. It is recommended that the MSB and LSB be treated as two independent sub-registers. One can either change the clock selection (MSB) and then change bits D[2:0] (LSB) on the SECOND write, or vice-versa. No order or sequence is necessary.

**FIGURE 25. TRANSMIT CLOCK AND INPUT DATA TIMING**

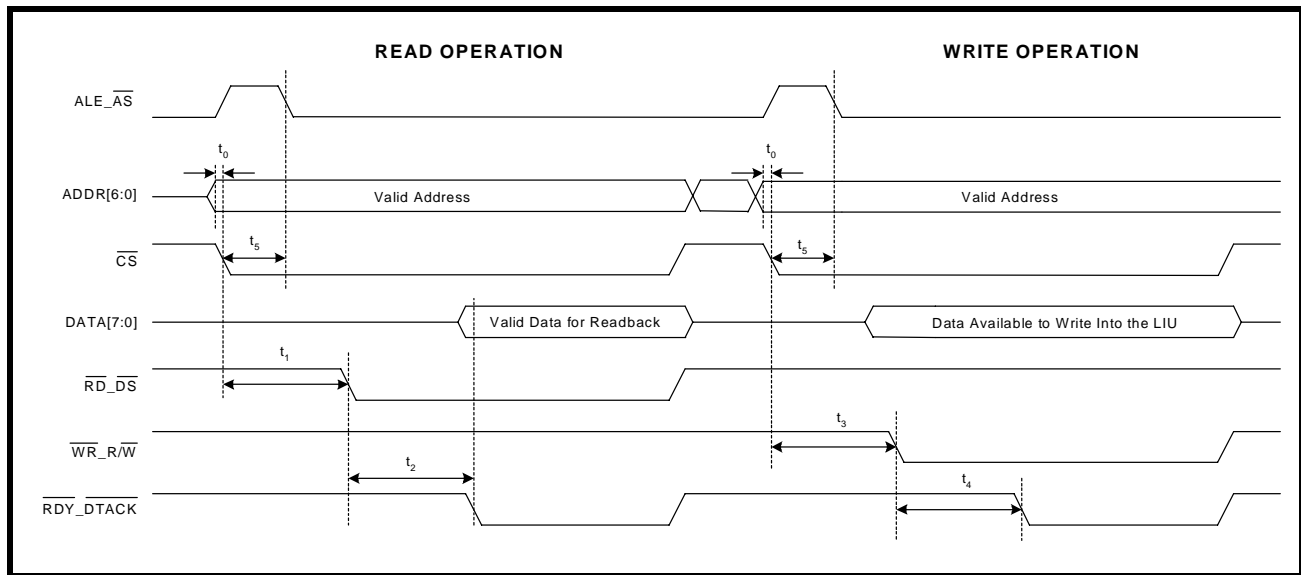

**FIGURE 26. RECEIVE CLOCK AND OUTPUT DATA TIMING**

**MICROPROCESSOR INTERFACE I/O TIMING**

**INTEL INTERFACE TIMING - ASYNCHRONOUS**

The signals used for the Intel microprocessor interface are: Address Latch Enable (ALE), Read Enable ( $\overline{RD}$ ), Write Enable ( $\overline{WR}$ ), Chip Select ( $\overline{CS}$ ), Address and Data bits. The microprocessor interface uses minimum external glue logic and is compatible with the timings of the 8051 or 80C188 with an 8-16 MHz clock frequency, and with the timings of x86 or i960 family or microprocessors. The interface timing shown in **Figure 27** and **Figure 29** is described in **Table 51**.

**FIGURE 27. INTEL ASYNCHRONOUS PROGRAMMED I/O INTERFACE TIMING**

**TABLE 51: ASYNCHRONOUS MODE 1 - INTEL 8051 AND 80188 INTERFACE TIMING**

SYMBOL	PARAMETER	MIN	MAX	UNITS
t <sub>0</sub>	Valid Address to $\overline{CS}$ Falling Edge	0	-	ns
t <sub>1</sub>	$\overline{CS}$ Falling Edge to $\overline{RD}$ Assert	20	-	ns
t <sub>2</sub>	$\overline{RD}$ Assert to $\overline{RDY}$ Assert	-	135	ns
NA	$\overline{RD}$ Pulse Width (t <sub>2</sub> )	135	-	ns
t <sub>3</sub>	$\overline{CS}$ Falling Edge to $\overline{WR}$ Assert	20	-	ns
t <sub>4</sub>	$\overline{WR}$ Assert to $\overline{RDY}$ Assert	-	135	ns
NA	$\overline{WR}$ Pulse Width (t <sub>2</sub> )	135	-	ns
t <sub>5</sub>	$\overline{CS}$ Falling Edge to $\overline{AS}$ Falling Edge	0	-	ns
<b>Reset pulse width - both Motorola and Intel Operations (see Figure 29)</b>				
t <sub>9</sub>	Reset pulse width	10		μs

**MOTOROLA ASYNCHRONOUS INTERFACE TIMING**

The signals used in the Motorola microprocessor interface mode are: Address Strobe (AS), Data Strobe ( $\overline{DS}$ ), Read/Write Enable ( $\overline{R/W}$ ), Chip Select ( $\overline{CS}$ ), Address and Data bits. The interface is compatible with the timing of a Motorola 68000 microprocessor family with up to 16.67 MHz clock frequency. The interface timing is shown in Figure 28 and Figure 29. The I/O specifications are shown in Table 52.

**FIGURE 28. MOTOROLA 68K ASYNCHRONOUS PROGRAMMED I/O INTERFACE TIMING**

**TABLE 52: ASYNCHRONOUS - MOTOROLA 68K - INTERFACE TIMING SPECIFICATION**

SYMBOL	PARAMETER	MIN	MAX	UNITS
$t_0$	Valid Address to $\overline{CS}$ Falling Edge	0	-	ns
$t_1$	$\overline{CS}$ Falling Edge to $\overline{DS}$ Assert	20	-	ns
$t_2$	$\overline{DS}$ Assert to $\overline{DTACK}$ Assert	-	135	ns
NA	$\overline{DS}$ Pulse Width ( $t_2$ )	135	-	ns
$t_3$	$\overline{CS}$ Falling Edge to $\overline{AS}$ Falling Edge	0	-	ns
<b>Reset pulse width - both Motorola and Intel Operations (see Figure 29)</b>				
$t_9$	$\overline{Reset}$ pulse width	10		$\mu$ s

**XRT83SL38**

**REV. 1.0.2 OCTAL T1/E1/J1 SH TRANSCEIVER WITH CLOCK RECOVERY AND JITTER ATTENUATOR**

**ORDERING INFORMATION**

PART NUMBER	PACKAGE	OPERATING TEMPERATURE RANGE
XRT83SL38IB	225 Ball BGA	-40°C to +85°C

**REVISIONS**

REV #	DESCRIPTION
P1.0.0	Initial data sheet
P101	Edits
P102	Reformatted columns.
P1.0.3	corrected microprocessor timing information and edited Redundancy section.
P1.0.4	Made edits to RLOS section. Table 4, EQC4 and EQC3 changed. RX transformer changed from 2:1 to 1:1. Removed references to 1:2.42 transformer ratio.
P1.0.5	Definition of TXON_n pin changed. Added detailed explanation of LOS operation. Added description of arbitrary pulse. Added description of the operation of the TRATIO bit. Added description of Gap Clock Support.
P1.0.6	Changed issue date to November 2002. Corrected BGA pinout.
P1.0.7	Swapped the function of $\mu$ PTS1 and $\mu$ PTS2. Replaced $\mu$ Processor timing diagrams and timing information, (Figures 27 and 28 -- Tables 50 and 51).
P1.0.8	Removed EXT_VCM_[0-7] and made them No Connect pins. MCLKT1 changed to pin K1, TGND_0 changed to pin D3 and D3 made NC. SR_DR moved to pin K4.
P1.0.9	Added RXON_n to bit 5 Control register 0.
P1.1.0	Added new E1 arbitrary pulse feature. Added description to the global registers.
1.0.0	Final release.
1.0.1	Added (Exar recommends initiating a HW reset upon power up.) to the Hardware rest pin description. In figure 30 and in tables 51 and 52 changed t9 to 10 ( $\mu$ s). Changed format to add new logo.
1.0.2	Remove XRT83SL38IV product info.

**NOTICE**

EXAR Corporation reserves the right to make changes to the products contained in this publication in order to improve design, performance or reliability. EXAR Corporation assumes no responsibility for the use of any circuits described herein, conveys no license under any patent or other right, and makes no representation that the circuits are free of patent infringement. Charts and schedules contained here in are only for illustration purposes and may vary depending upon a user's specific application. While the information in this publication has been carefully checked; no responsibility, however, is assumed for inaccuracies.

EXAR Corporation does not recommend the use of any of its products in life support applications where the failure or malfunction of the product can reasonably be expected to cause failure of the life support system or to significantly affect its safety or effectiveness. Products are not authorized for use in such applications unless EXAR Corporation receives, in writing, assurances to its satisfaction that: (a) the risk of injury or damage has been minimized; (b) the user assumes all such risks; (c) potential liability of EXAR Corporation is adequately protected under the circumstances.

Компания «Океан Электроники» предлагает заключение долгосрочных отношений при поставках импортных электронных компонентов на взаимовыгодных условиях!

Наши преимущества:

- Поставка оригинальных импортных электронных компонентов напрямую с производств Америки, Европы и Азии, а так же с крупнейших складов мира;
- Широкая линейка поставок активных и пассивных импортных электронных компонентов (более 30 млн. наименований);
- Поставка сложных, дефицитных, либо снятых с производства позиций;
- Оперативные сроки поставки под заказ (от 5 рабочих дней);
- Экспресс доставка в любую точку России;
- Помощь Конструкторского Отдела и консультации квалифицированных инженеров;
- Техническая поддержка проекта, помощь в подборе аналогов, поставка прототипов;
- Поставка электронных компонентов под контролем ВП;
- Система менеджмента качества сертифицирована по Международному стандарту ISO 9001;
- При необходимости вся продукция военного и аэрокосмического назначения проходит испытания и сертификацию в лаборатории (по согласованию с заказчиком);
- Поставка специализированных компонентов военного и аэрокосмического уровня качества (Xilinx, Altera, Analog Devices, Intersil, Interpoint, Microsemi, Actel, Aeroflex, Peregrine, VPT, Syfer, Eurofarad, Texas Instruments, MS Kennedy, Miteq, Cobham, E2V, MA-COM, Hittite, Mini-Circuits, General Dynamics и др.);

Компания «Океан Электроники» является официальным дистрибьютором и эксклюзивным представителем в России одного из крупнейших производителей разъемов военного и аэрокосмического назначения «JONHON», а так же официальным дистрибьютором и эксклюзивным представителем в России производителя высокотехнологичных и надежных решений для передачи СВЧ сигналов «FORSTAR».

## JONHON

«JONHON» (основан в 1970 г.)

Разъемы специального, военного и аэрокосмического назначения:

(Применяются в военной, авиационной, аэрокосмической, морской, железнодорожной, горно- и нефтедобывающей отраслях промышленности)

«FORSTAR» (основан в 1998 г.)

ВЧ соединители, коаксиальные кабели, кабельные сборки и микроволновые компоненты:

(Применяются в телекоммуникациях гражданского и специального назначения, в средствах связи, РЛС, а так же военной, авиационной и аэрокосмической отраслях промышленности).
