MC100EP40

3.3V / 5V ECL Differential Phase-Frequency Detector

ON Semiconductor®

http://onsemi.com

Description

The MC100EP40 is a three−state phase−frequency detector intended for phase−locked loop applications which require a minimum amount of phase and frequency difference at lock. Advanced design significantly reduces the dead zone of the detector. For proper operation, the input edge rate of the R and V inputs should be less than 5 ns. The device is designed to work with a 3.3 V / 5 V power supply.

When Reference (R) and Feedback (FB) inputs are unequal in frequency and/or phase the differential UP (U) and DOWN (D) outputs will provide pulse streams which when subtracted and integrated provide an error voltage for control of a VCO.

When Reference (R) and Feedback (FB) inputs are 80 ps or less in phase difference, the Phase Lock Detect pin will indicate lock by a high state (V_{OH}). The V_{TX} (V_{TR}, $\overline{V_{TR}}$, V_{TFB}, $\overline{V_{TFB}}$) pins offer an internal termination network for 50 Ω line impedance environment shown in Figure 2. An external sinking supply of V_{CC}−2 V is required on V_{TX} pin(s). If you short the two differential V_{TR} and $\overline{V_{TR}}$ (or V_{TFB} and $\overline{V_{TFB}}$) together, you provide a 100 Ω termination resistance that is compatible with LVDS signal receiver termination. For more information on termination of logic devices, see AND8020.

The V_{BB} pin, an internally generated voltage supply, is available to this device only. For single-ended input conditions, the unused differential input is connected to V_{BB} as a switching reference voltage. V_{BB} may also rebias AC coupled inputs. When used, decouple V_{BB} and V_{CC} via a 0.01 μF capacitor and limit current sourcing or sinking to 0.5 mA. When not used, V_{BB} should be left open.

For more information on Phase Lock Loop operation, refer to AND8040.

Special considerations are required for differential inputs under No Signal conditions to prevent instability.
