

# TLE9263-3BQX

## System Basis Chip

### Mid-Range+ System Basis Chip Family

### Quality Requirement Category: Automotive

#### Features

- Two integrated Low-Drop Voltage Regulators: Main regulator (5 V or 3.3 V up to 250 mA) and auxiliary regulator (5 V up to 100 mA) with off-board usage protection
- Voltage regulator (5 V, 3.3 V or 1.8 V) with external PNP transistor configurable for off-board usage or for load sharing
- 1 high-speed CAN transceiver supporting FD communication up to 5 Mbit/s featuring CAN Partial Networking & CAN FD tolerant mode according to ISO 11898-2:2016 & SAE J2284
- 2 LIN transceivers LIN2.2A/J2602
- 4 high-side outputs 7  $\Omega$  typ., 2 HV GPIOs, 3 HV wake inputs
- Integrated fail-safe and supervision functions, e.g. fail-safe, watchdog, interrupt- and reset outputs
- 16-bit SPI for configuration and diagnostics

#### Applications

- Body Control Modules (BMC), Passive keyless entry and start modules, Gateway applications
- Heating, ventilation and air conditioning (HVAC)
- Seat, roof, tailgate, trailer, door and other closure modules
- Light control modules
- Gear shifters and selectors

#### Description

Body System IC with Integrated Voltage Regulators, Power Management Functions, HS-CAN Transceiver supporting CAN FD featuring Partial Networking (incl. FD Tolerant Mode) and Multiple LIN Transceiver. Featuring Multiple High-Side Switches and High-Voltage Wake Inputs.

| Type         | Package       | Marking      |
|--------------|---------------|--------------|
| TLE9263-3BQX | PG-VQFN-48-31 | TLE9263-3BQX |

**Overview**

## 1 Overview

### Scalable System Basis Chip Family

- Product family with various products for complete scalable application coverage.
- Dedicated Data Sheets are available for the different product variants
- Complete compatibility (hardware and software) across the family
- TLE9263 with 2 LIN transceivers, 3 voltage regulators
- TLE9262 with 1 LIN transceiver, 3 voltage regulators
- TLE9261 without LIN transceivers, 3 voltage regulators
- Product variants for 5V (TLE926xQX) and 3.3V (TLE926xQXV33) output voltage for main voltage regulator
- CAN Partial Networking variants for 5V (TLE926x-3QX) and 3.3V (TLE926x-3QXV33) output voltage

### Device Description

The TLE9263-3BQX is a monolithic integrated circuit in an exposed pad VQFN-48 (7mm x 7mm) power package with Lead Tip Inspection (LTI) feature to support Automatic Optical Inspection (AOI).

The device is designed for various CAN-LIN automotive applications as main supply for the microcontroller and as interface for a LIN and CAN bus network including the CAN Partial Networking feature.

To support these applications, the System Basis Chip (SBC) provides the main functions, such as a 5V low-dropout voltage regulator (LDO) for e.g. a microcontroller supply, another 5V low-dropout voltage regulator with off-board protection for e.g. sensor supply, another 5V/3.3V regulator to drive an external PNP transistor, which can be used as an independent supply for off-board usage or in load sharing configuration with the main regulator VCC1, a HS-CAN transceiver supporting CAN FD and CAN Partial Networking (incl. FD tolerant mode) and LIN transceiver for data transmission, high-side switches with embedded protective functions and a 16-bit Serial Peripheral Interface (SPI) to control and monitor the device. Also implemented are a configurable timeout / window watchdog circuit with a reset feature, three Fail Outputs and an undervoltage reset feature.

The device offers low-power modes in order to minimize current consumption on applications that are connected permanently to the battery. A wake-up from the low-power mode is possible via a message on the buses, via the bi-level sensitive monitoring/wake-up inputs as well as via cyclic wake.

The device is designed to withstand the severe conditions of automotive applications.

---

**Overview****Product Features**

- Very low quiescent current consumption in Stop- and Sleep Mode
- Periodic Cyclic Wake in SBC Normal- and Stop Mode
- Periodic Cyclic Sense in SBC Normal-, Stop- and Sleep Mode
- Low-Drop Voltage Regulator 5V, 250mA
- Low-Drop Voltage Regulator 5V, 100mA, protected features for off-board usage
- Low-Drop Voltage Regulator, driving an external PNP transistor - 5V in load sharing configuration or 5V/3.3V in stand-alone configuration, protected features for off-board usage. Current limitation by shunt resistor (up to 350mA with 470mΩ external shunt resistor) in stand-alone configuration
- High-Speed CAN Transceiver:
  - fully compliant to HS-CAN standard ISO 11898-2:2016
  - fully compliant to CAN Partial Networking including CAN FD tolerant feature (acc. ISO 11898-2:2016)
  - supporting CAN FD communication up to 5 Mbps
- Two LIN Transceivers LIN 2.2a, J2602 with configurable TXD timeout feature and LIN Flash Mode
- Fully compliant to “Hardware Requirements for LIN, CAN and FlexRay Interfaces in Automotive Applications” Revision 1.3, 2012-05-04
- Four High-Side Outputs 7Ω typ.
- Dedicated supply pin for High-Side Outputs
- Two General Purpose High-Voltage In- and Outputs (GPIOs) configurable as add. Fail Outputs, Wake Inputs, Low-Side switches or High-Side switches
- Three universal High-Voltage Wake Inputs for voltage level monitoring
- Alternate High-Voltage Measurement Function, e.g. for battery voltage sensing
- Configurable wake-up sources
- Reset Output
- Configurable timeout and window watchdog
- Up to three Fail Outputs (depending on configuration)
- Overtemperature and short circuit protection feature
- Wide supply input voltage and temperature range
- Software compatible to all SBC families TLE926x and TLE927x
- Green Product (RoHS compliant) & AEC Qualified
- PG-VQFN-48 leadless exposed-pad power package with Lead Tip Inspection (LTI) feature to support Automatic Optical Inspection (AOI)

| 47          | FO2      | <b>Fail Output 2</b> - Side Indicator; Side indicators 1.25Hz 50% duty cycle output; Open drain. Active LOW.<br><b>Alternative Function: GPIO1</b> ; configurable pin as WK, or LS, or HS supplied by VSHS (default is FO2, see also <a href="#">Chapter 14.1.1</a> )                                                                                                                                                                            |
| 48          | FO3/TEST | <b>Fail Output 3</b> - Pulsed Light Output; Break/rear light 100Hz 20% duty cycle output; Open drain. Active LOW<br><b>TEST</b> ; Connect to GND to activate SBC Development Mode; Integrated pull-up resistor. Connect to VS with pull-up resistor or leave open for normal operation.<br><b>Alternative Function: GPIO2</b> ; configurable pin as WK, or LS, or HS supplied by VSHS (default is FO3, see also <a href="#">Chapter 14.1.1</a> ) |
| Cooling Tab | GND      | Cooling Tab - Exposed Die Pad; For cooling purposes only, do not use as an electrical ground. <sup>1)</sup>                                                                                                                                                                                                                                                                                                                                      |

- 1) The exposed die pad at the bottom of the package allows better power dissipation of heat from the SBC via the PCB. The exposed die pad is not connected to any active part of the IC and can be left floating or it can be connected to GND (recommended) for the best EMC performance.

**Note:** *all VS Pins must be connected to battery potential or insert a reverse polarity diodes where required;  
all GND pins as well as the Cooling Tab must be connected to one common GND potential;  
note that the tie bars at each package corner are connected to the cooling tab (see also [Chapter 18](#))*

## Pin Configuration

### 3.3 Hints for Unused Pins

It must be ensured that the correct configurations are also selected, i.e. in case functions are not used that they are disabled via SPI:

- WK1/2/3: connect to GND and disable WK inputs via SPI
- HSx: leave open
- LINx, RXDLINx, TXDLINx, CANH/L, RXDCAN, TXDCAN: leave all pins open
- RO / FOx: leave open
- INT: leave open
- TEST: connect to GND during power-up to activate SBC Development Mode; connect to VS or leave open for normal user mode operation
- VCC2: leave open and keep disabled
- VCC3: See [Chapter 8.5](#)
- VCAN: connect to VCC1
- n.c.: not connected; internally not bonded; connect to GND
- If unused pins are routed to an external connector which leaves the ECU, then these pins should have provision for a zero ohm jumper (depopulated if unused) or ESD protection.

### 3.4 Hints for Alternate Pin Functions

In case of alternate pin functions, selectable via SPI, it must be ensured that the correct configurations are also selected via SPI, in case it is not done automatically. Please consult the respective chapter. In addition, following topics shall be considered:

- WK1..2: The pins can be either used as HV wake / voltage monitoring inputs or for a voltage measurement function (via bit [WK\\_MEAS](#)). In the second case, the WK1..2 pins shall not be used / assigned for any wake detection nor cyclic sense functionality, i.e. WK1 and WK2 must be disabled in the register [WK\\_CTRL\\_2](#) and the level information is to be ignored in the register [WK\\_LVL\\_STAT](#).
- FO2..3: The pins can also be configured as GPIOs in the [GPIO\\_CTRL](#) register. In this case, the pins shall not be used for any fail output functionality. The default function after Power on Reset (POR) is FOx.

## 4 General Product Characteristics

### 4.1 Absolute Maximum Ratings

**Table 1 Absolute Maximum Ratings<sup>1)</sup>**

$T_j = -40\text{ °C to }+150\text{ °C}$ ; all voltages with respect to ground, positive current flowing into pin (unless otherwise specified)

| ESD Resistivity to GND                                                 | $V_{\text{ESD},21}$ | -500   | –    | 500  | V    | CDM <sup>5)</sup>        | P_4.1.20 |
| ESD Resistivity Pin 1,<br>12,13,24,25,36,37,48 (corner<br>pins) to GND | $V_{\text{ESD},22}$ | -750   | –    | 750  | V    | CDM <sup>5)</sup>        | P_4.1.21 |

1) Not subject to production test, specified by design.

2) Applies only if WK1 and WK2 are configured as alternative HV-measurement function

3) ESD susceptibility, HBM according to ANSI/ESDA/JEDEC JS-001 (1.5 kΩ, 100 pF)

4) For ESD "GUN" Resistivity 6kV (according to IEC61000-4-2 "gun test" (150pF, 330Ω)), will be shown in Application Information and test report will be provided from IBEE

5) ESD susceptibility, Charged Device Model "CDM" EIA/JESD22-C101 or ESDA STM5.3.1

**Notes**

1. Stresses above the ones listed here may cause permanent damage to the device. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.
2. Integrated protection functions are designed to prevent IC destruction under fault conditions described in the data sheet. Fault conditions are considered as "outside" normal operating range. Protection functions are not designed for continuous repetitive operation.

## 4.2 Functional Range

**Table 2 Functional Range**

| Parameter            | Symbol           | Values    |      |      | Unit | Note / Test Condition                                             | Number  |
|----------------------|------------------|-----------|------|------|------|-------------------------------------------------------------------|---------|
|                      |                  | Min.      | Typ. | Max. |      |                                                                   |         |
| Supply Voltage       | $V_{S,func}$     | $V_{POR}$ | –    | 28   | V    | <sup>1)</sup> $V_{POR}$ see section <a href="#">Chapter 15.10</a> | P_4.2.1 |
| LIN Bus Voltage      | $V_{S,LIN,func}$ | 6         | –    | 18   | V    | <sup>2)</sup>                                                     | P_4.2.2 |
| CAN Supply Voltage   | $V_{CAN,func}$   | 4.75      | –    | 5.25 | V    | –                                                                 | P_4.2.3 |
| SPI frequency        | $f_{SPI}$        | –         | –    | 4    | MHz  | see <a href="#">Chapter 16.7</a> for $f_{SPI,max}$                | P_4.2.4 |
| Junction Temperature | $T_j$            | -40       | –    | 150  | °C   | –                                                                 | P_4.2.5 |

1) Including Power-On Reset, Over- and Undervoltage Protection

2) Parameter Specification according to LIN 2.2 standard

*Note: Within the functional range the IC operates as described in the circuit description. The electrical characteristics are specified within the conditions given in the related electrical characteristics table.*

Device Behavior Outside of Specified Functional Range:

- $28V < V_{S,func} < 40V$ : Device will still be functional including the state machine; the specified electrical characteristics might not be ensured anymore. The regulators VCC1/2/3 are working properly, however, a thermal shutdown might occur due to high power dissipation. HSx switches might be turned OFF depending on VSHS\_OV configurations. The specified SPI communication speed is ensured; the absolute maximum ratings are not violated, however the device is not intended for continuous operation of  $V_S > 28V$ . The device operation at high junction temperatures for long periods might reduce the operating life time;
- $18V < V_{S,LIN} < 28V$ : The LIN transceiver is still functional. However, the communication might fail due to out-of-LIN-spec operation;
- $V_{SHS,UVD} < V_{S,LIN} < 6V$ : The LIN transceiver is still functional. However, the communication might fail due to out-of-LIN-spec operation;
- $V_{CAN} < 4.75V$ : The undervoltage bit **VCAN\_UV** will be set in the SPI register **BUS\_STAT\_1** and the transmitter will be disabled as long as the UV condition is present;
- $5.25V < V_{CAN} < 5.50V$ : CAN transceiver still functional. However, the communication might fail due to out-of-spec operation;
- $V_{POR,f} < V_S < 5.5V$ : Device will still be functional; the specified electrical characteristics might not be ensured anymore.
  - The voltage regulators will enter the low-drop operation mode (applies for VCC3 only if bit **VCC3\_VS\_UV\_OFF** is set),
  - A VCC1\_UV reset could be triggered depending on the Vrtx settings,
  - The LIN transmitter will be disabled if  $V_{SHS,UVD}$  is reached,
  - HSx switch behavior will depend on the respective configuration:
    - **HS\_UV\_SD\_EN** = '0' (default): HSx will be turned OFF for  $VSHS < VSHS_{UV}$  and will stay OFF;
    - **HS\_UV\_SD\_EN** = '1': HSx stays on as long as possible. An unwanted overcurrent shut down may occur. OC shut down bit set and the respective HSx switch will stay OFF;
  - FOx outputs will remain ON if they were enabled before  $V_S > 5.5V$ ,
  - The specified SPI communication speed is ensured.

### 4.3 Thermal Resistance

**Table 3 Thermal Resistance<sup>1)</sup>**

| Parameter                   | Symbol      | Values |      |      | Unit | Note / Test Condition | Number  |
|-----------------------------|-------------|--------|------|------|------|-----------------------|---------|
|                             |             | Min.   | Typ. | Max. |      |                       |         |
| Junction to Soldering Point | $R_{thJSP}$ | –      | 6    | –    | K/W  | Exposed Pad           | P_4.3.1 |
| Junction to Ambient         | $R_{thJA}$  | –      | 33   | –    | K/W  | <sup>2)</sup>         | P_4.3.2 |

1) Not subject to production test, specified by design.

2) According to Jedec JESD51-2,-5,-7 at natural convection on FR4 2s2p board for 1.5W. Board: 76.2x114.3x1.5mm<sup>3</sup> with 2 inner copper layers (35µm thick), with thermal via array under the exposed pad contacting the first inner copper layer and 300mm<sup>2</sup> cooling area on the bottom layer (70µm).

## 4.4 Current Consumption

**Table 4 Current Consumption**

Current consumption values are specified at  $T_j = 25^\circ\text{C}$ ,  $V_S = 13.5\text{V}$ , all outputs open (unless otherwise specified)

| Parameter                                                     | Symbol                   | Values |      |      | Unit | Note / Test Condition                                                                                                                                                                              | Number   |

| Current consumption for active fail outputs (FO1..3)                        | $I_{\text{Stop,FOx}}$      | —      | 1.0  | 2.0  | $\text{mA}$   | <sup>3)</sup> all SBC Modes; $T_j = 25^\circ\text{C}$ ; FOx = ON (no load);                                                   | P_4.4.24 |

- 1) If the load current on VCC1 will exceed the configured VCC1 active peak threshold  $I_{\text{VCC1,peak1,r}}$  or  $I_{\text{VCC1,peak2,r}}$ , the current consumption will increase by typ. 2.9mA to ensure optimum dynamic load behavior. Same applies to VCC2. For VCC3 the current consumption will increase by typ. 1.4mA. See also [Chapter 6](#), [Chapter 7](#), [Chapter 8](#).
- 2) CAN not configured in selective wake mode.
- 3) Not subject to production test, specified by design.
- 4) Current consumption adder also applies for during WUF detection (frame detect mode) when CAN Partial Networking is activated.
- 5) Current consumption adders of features defined for SBC Sleep Mode also apply for SBC Stop Mode and vice versa (unless otherwise specified).

---

**General Product Characteristics**

- 6) No pull-up or pull-down configuration selected.
- 7) The specified WKx current consumption adder for wake capability applies regardless how many WK inputs are activated.
- 8) A typ. 75µA / max 125µA ( $T_j = 85^\circ\text{C}$ ) adder applies for every additionally activated HSx switch in SBC Stop Mode;  
In SBC Normal Mode every HSx switch consumes the typ. 75µA / max 125µA ( $T_j = 85^\circ\text{C}$ ) without the initial adder because the biasing is already enabled.
- 9) HS1 used for cyclic sense, Timer 2, 20ms period, 0.1ms on-time, no load on HS1.

In general the current consumption adder for cyclic sense in SBC Stop Mode can be calculated with below equation:  
 $I_{\text{Stop,CS}} = 18\mu\text{A} + (525\mu\text{A} \cdot t_{\text{ON}}/T_{\text{Per}})$

- 10) Also applies to Cyclic Wake

*Note: There is no additional current consumption contribution due to PWM generators.*

## System Features

# 5 System Features

This chapter describes the system features and behavior of the TLE9263-3BQX:

- State machine
- SBC mode control
- Device configuration
- State of supply and peripherals
- System functions such as cyclic sense or cyclic wake
- Supervision and diagnosis functions

The System Basis Chip (SBC) offers six operating modes:

- SBC Init Mode: Power-up of the device and after a soft reset,
- SBC Normal Mode: The main operating mode of the device,
- SBC Stop Mode: The first-level power saving mode with the main voltage regulator VCC1 enabled,
- SBC Sleep Mode: The second-level power saving mode with VCC1 disabled,
- SBC Restart Mode: An intermediate mode after a wake event from SBC Sleep or Fail-Safe Mode or after a failure (e.g. WD failure, VCC1 undervoltage reset) to bring the microcontroller into a defined state via a reset. Once the failure condition is not present anymore the device will automatically change to SBC Normal Mode after a delay time ( $t_{RD1}$ ).
- SBC Fail-Safe Mode: A safe-state mode after critical failures (e.g. WD failure, VCC1 undervoltage reset) to bring the system into a safe state and to ensure a proper restart of the system. VCC1 is disabled. It is a permanent state until either a wake event (via CAN, LINx or WKx) occurs or the overtemperature condition is not present anymore.

A special mode, called SBC Development Mode, is available during software development or debugging of the system. All above mentioned operating modes can be accessed in this mode. However, the watchdog counter is stopped and does not need to be triggered. This mode can be accessed by setting the TEST pin to GND during SBC Init Mode.

The device can be configured via hardware (external component) to determine the device behavior after a watchdog trigger failure. See [Chapter 5.1.1](#) for further information.

The System Basis Chip is controlled via a 16-bit SPI interface. A detailed description can be found in [Chapter 16](#). The configuration as well as the diagnosis is handled via the SPI. The SPI mapping of the TLE9263-3BQX is compatible to other devices of the TLE926x and TLE927x families.

## System Features

### 5.1 Block Description of State Machine

The different SBC Modes are selected via SPI by setting the respective SBC **MODE** bits in the register **M\_S\_CTRL**. The SBC **MODE** bits are cleared when going through SBC Restart Mode and thus always show the current SBC mode.

**Figure 3 State Diagram showing the SBC Operating Modes including CAN Partial Networking**

## System Features

### 5.1.1 Device Configuration and SBC Init Mode

The SBC starts up in SBC Init Mode after crossing the power-on reset  $V_{POR,r}$  threshold (see also [Chapter 15.3](#)) and the watchdog will start with a long open window ( $t_{LW}$ ).

During this power-on phase following configurations are stored in the device:

- The device behavior regarding a watchdog trigger failure and a VCC1 overvoltage condition is determined by the external circuitry on the INT pin (see below)
- The selection of the normal device operation or the SBC Development Mode (watchdog disabled for debugging purposes) will be set depending on the voltage level of the FO3/TEST pin (see also [Chapter 5.1.7](#)).

#### 5.1.1.1 Device Configuration

The configuration selection is intended to select the SBC behavior regarding a watchdog trigger failure. Depending on the requirements of the application, the VCC1 output shall be switched OFF and the device shall go to SBC Fail-Safe Mode in case of a watchdog failure (1 or 2 fails). To set this configuration (Config 2/4), the INT pin does not need an external pull-up resistor. In case VCC1 should not be switched OFF (Config 1/3), the INT pin needs to have an external pull-up resistor connected to VCC1 (see application diagram in [Chapter 17.1](#)).

[Figure 5](#) shows the timing diagram of the hardware configuration selection. The hardware configuration is defined during SBC Init Mode. The INT pin is internally pulled LOW with a weak pull-down resistor during the reset delay time  $t_{RD1}$ , i.e. after VCC1 crosses the reset threshold VRT1 and before the RO pin goes HIGH. The INT pin is monitored during this time (with a continuous filter time of  $t_{CFG_F}$ ) and the configuration (depending on the voltage level at INT) is stored at the rising edge of RO.

**Note:** *If the **POR** bit is not cleared then the internal pull-down resistor will be reactivated every time RO is pulled LOW the configuration will be updated at the rising edge of RO. Therefore it is recommended to clear the **POR** bit right after initialization. In case there is no stable signal at INT, then the default value '0' will be taken as the config select value = SBC Fail-Safe Mode.*

## System Features

**Figure 4** Hardware Configuration Selection Timing Diagram

There are four different device configurations ([Table 5](#)) available defining the watchdog failure and the VCC1 overvoltage behavior. The configurations can be selected via the external connection on the INT pin and the SPI bit **CFG** in the **HW\_CTRL** register (see also [Chapter 16.4](#)):

- **CFG** = '1': Config 1 and Config 3:
  - A watchdog trigger failure leads to SBC Restart Mode and depending on **CFG** the Fail Outputs (FOx) are activated after the 1st (Config 1) or 2nd (Config 3) watchdog trigger failure;
  - A VCC1 overvoltage detection will lead to SBC Restart Mode if **VCC1\_OV\_RST** is set. **VCC1\_OV** will be set and the Fail Outputs are activated;
- **CFG** = '0': Config 2 and Config 4:
  - A watchdog trigger failure leads to SBC Fail-Safe Mode and depending on **CFG** the Fail Outputs (FOx) are activated after the 1st (Config 2) or 2nd (Config 4) watchdog trigger failure. The first watchdog trigger failure in Config 4 will lead to SBC Restart Mode;
  - A VCC1 overvoltage detection will lead to SBC Fail-Safe Mode if **VCC1\_OV\_RST** is set. **VCC1\_OV** will be set and the Fail Outputs are activated;

The respective device configuration can be identified by reading the SPI bit **CFG** in the **HW\_CTRL** register and the **CFG** bit in the **WK\_LVL\_STAT** register.

[Table 5](#) shows the configurations and the device behavior in case of a watchdog trigger failure:

**Table 5** Watchdog Trigger Failure Configuration

| Config | INT Pin ( <b>CFG</b> ) | SPI Bit <b>CFG</b> | Event                | FOx Activation       | SBC Mode Entry     |
|--------|------------------------|--------------------|----------------------|----------------------|--------------------|
| 1      | External pull-up       | 1                  | 1 x Watchdog Failure | after 1st WD Failure | SBC Restart Mode   |
| 2      | No ext. pull-up        | 1                  | 1 x Watchdog Failure | after 1st WD Failure | SBC Fail-Safe Mode |
| 3      | External pull-up       | 0                  | 2 x Watchdog Failure | after 2nd WD Failure | SBC Restart Mode   |
| 4      | No ext. pull-up        | 0                  | 2 x Watchdog Failure | after 2nd WD Failure | SBC Fail-Safe Mode |

## System Features

**Table 6** shows the configurations and the device behavior in case of a VCC1 overvoltage detection when **VCC1\_OV\_RST** is set:

**Table 6 Device Behavior in Case of VCC1 Overvoltage Detection**

| Config | INT Pin (CFG_P)  | CFG Bit | VCC1_OV_RST | Event       | VCC1_OV | FOx Activation    | SBC Mode Entry     |
|--------|------------------|---------|-------------|-------------|---------|-------------------|--------------------|
| 1-4    | any value        | x       | 0           | 1 x VCC1 OV | 1       | no FOx activation | unchanged          |
| 1      | External pull-up | 1       | 1           | 1 x VCC1 OV | 1       | after 1st VCC1 OV | SBC Restart Mode   |
| 2      | No ext. pull-up  | 1       | 1           | 1 x VCC1 OV | 1       | after 1st VCC1 OV | SBC Fail-Safe Mode |
| 3      | External pull-up | 0       | 1           | 1 x VCC1 OV | 1       | after 1st VCC1 OV | SBC Restart Mode   |
| 4      | No ext. pull-up  | 0       | 1           | 1 x VCC1 OV | 1       | after 1st VCC1 OV | SBC Fail-Safe Mode |

The respective configuration will be stored for all conditions and can only be changed by powering down the device ( $V_S < V_{POR,f}$ ).

## System Features

### 5.1.1.2 SBC Init Mode

In SBC Init Mode, the device waits for the microcontroller to finish its startup and initialization sequence. In the SBC Init Mode any valid SPI command will bring the SBC to SBC Normal Mode. During the long open window the watchdog has to be triggered. Thereby the watchdog will be automatically configured.

A missing watchdog trigger during the long open window will cause a watchdog failure and the device will enter SBC Restart Mode.

Wake events are ignored during SBC Init Mode and will therefore be lost.

*Note:* Any SPI command will bring the SBC to SBC Normal Mode even if it is a illegal SPI command (see [Chapter 16.2](#)).

*Note:* For a safe start-up, it is recommended to use the first SPI command to trigger and to configure the watchdog (see [Chapter 15.2](#)).

*Note:* At power up no **VCC1\_UV** will be issued nor will FOx be triggered as long as VCC1 is below the  $V_{RT,x}$  threshold and if VS is below the VCC1 short circuit detection threshold **V<sub>s,uv</sub>**. The RO pin will be kept low as long as VCC1 is below the selected  $V_{RT,x}$  threshold.

## System Features

### 5.1.2 SBC Normal Mode

The SBC Normal Mode is the standard operating mode for the SBC. All configurations have to be done in SBC Normal Mode before entering a low-power mode (see also [Chapter 5.1.6](#) for the device configuration defining the Fail-Safe Mode behavior). A wake-up event on CAN, LINx and WKx will create an interrupt on pin INT - however, no change of the SBC mode will occur. The configuration options are listed below:

- VCC1 is active
- VCC2 can be switched ON or OFF (default = OFF)
- VCC3 is configurable (OFF coming from SBC Init Mode; as previously programmed coming from SBC Restart Mode)
- CAN is configurable (OFF coming from SBC Init Mode; OFF or wake capable coming from SBC Restart Mode, see also [Chapter 5.1.5](#))
- LIN is configurable (OFF coming from SBC Init Mode; OFF or wake capable coming from SBC Restart Mode, see also [Chapter 5.1.5](#))
- HS Outputs can be switched ON or OFF (default = OFF) or can be controlled by PWM; HS Outputs are OFF coming from SBC Restart Mode
- Wake pins show the input level and can be selected to be wake capable (interrupt)
- Cyclic sense can be configured with HS1...4 and Timer1 or Timer 2
- Cyclic wake can be configured with Timer1 or Timer2
- Watchdog is configurable
- All FOx outputs are OFF by default. Coming from SBC Restart Mode FOx can be active (due to a failure event, e.g. watchdog trigger failure, VCC1 short circuit, etc.) or inactive (no failure occurred)

In SBC Normal Mode, there is the possibility of testing the FO outputs, i.e. to verify if setting the FO pin to low will create the intended behavior within the system. The FO output can be enabled and then disabled again by the microcontroller by setting the **FO\_ON** SPI bit. This feature is only intended for testing purposes.

## System Features

### 5.1.3 SBC Stop Mode

The SBC Stop Mode is the first level technique to reduce the overall current consumption by setting the voltage regulators VCC1, VCC2 and VCC3 into a low-power mode. In this mode VCC1 is still active and supplying the microcontroller, which can enter a power down mode. The VCC2 supply, CAN & LIN mode as well as the HSx outputs can be configured to stay enabled. All kind of settings have to be done before entering SBC Stop Mode. In SBC Stop Mode any kind of SPI WRITE commands are ignored and the **SPI\_FAIL** bit is set, except for changing to SBC Normal Mode, triggering a SBC Soft Reset, refreshing the watchdog as well as for reading and clearing the SPI status registers. A wake-up event on CAN, LINx and WKx will create an interrupt on pin INT - however, no change of the SBC mode will occur. The configuration options are listed below:

- VCC1 is ON
- VCC2 is fixed as configured in SBC Normal Mode
- VCC3 is fixed as configured in SBC Normal Mode
- CAN mode is fixed as configured in SBC Normal Mode
- LIN mode is fixed as configured in SBC Normal Mode
- WK pins are fixed as configured in SBC Normal Mode
- HS Outputs are fixed as configured in SBC Normal Mode
- Cyclic sense is fixed as configured in SBC Normal Mode
- Cyclic wake is fixed as configured in SBC Normal Mode
- Watchdog is fixed as configured in SBC Normal Mode
- SBC Soft Reset can be triggered
- FOx outputs are fixed, i.e. the state from SBC Normal Mode is maintained

An interrupt is triggered on the pin INT when SBC Stop Mode is entered and not all wake source signalization flags from **WK\_STAT\_1** and **WK\_STAT\_2** were cleared.

*Note: If switches are enabled during SBC Stop Mode, e.g. HSx on with or without PWM, then the SBC current consumption will increase (see **Chapter 4.4**).*

*Note: It is not possible to switch directly from SBC Stop Mode to SBC Sleep Mode. Doing so will also set the **SPI\_FAIL** flag and will bring the SBC into Restart Mode.*

*Note: When WK1 and WK2 are configured for the alternate measurement function (**WK\_MEAS** = 1) then the wake inputs cannot be selected as wake input sources.*

## System Features

### 5.1.4 SBC Sleep Mode

The SBC Sleep Mode is the second level technique to reduce the overall current consumption to a minimum needed to react on wake-up events or for the SBC to perform autonomous actions (e.g. cyclic sense). In this mode, VCC1 is OFF and not supplying the microcontroller anymore. The VCC2 supply as well as the HSx outputs can be configured to stay enabled. The settings have to be done before entering SBC Sleep Mode. A wake-up event on CAN, LINx or WKx will bring the device via SBC Restart Mode into SBC Normal Mode again and signal the wake source. The configuration options are listed below:

- VCC1 is OFF
- VCC2 is fixed as configured in SBC Normal Mode
- VCC3 is fixed or OFF as configured in SBC Normal Mode
- CAN mode changes automatically from ON or Receive Only Mode to wake capable mode or can be selected to be OFF
- LIN mode changes automatically from ON or Receive Only Mode to wake capable mode or can be selected to be OFF
- WK pins are fixed as configured in SBC Normal Mode
- HS Outputs are fixed as configured in SBC Normal Mode
- Cyclic sense is fixed as configured in SBC Normal Mode
- Cyclic wake is not available
- Watchdog is OFF
- FOx outputs are fixed, i.e. the state from SBC Normal Mode is maintained
- As VCC1 is OFF during SBC Sleep Mode, no SPI communication is possible;
- The Sleep Mode entry is signalled in the SPI register **DEV\_STAT** with the bit **DEV\_STAT**

It is not possible to switch all wake sources off in SBC Sleep Mode. Doing so will set the **SPI\_FAIL** flag and will bring the SBC into SBC Restart Mode.

In order to enter SBC Sleep Mode successfully, all wake source signalization flags from **WK\_STAT\_1** and **WK\_STAT\_2** need to be cleared. A failure to do so will result in an immediate wake-up from SBC Sleep Mode by going via SBC Restart to Normal Mode.

All settings must be done before entering SBC Sleep Mode.

*Note: If switches are enabled during SBC Sleep mode, e.g. HSx on with or without PWM, then the SBC current consumption will increase (see **Chapter 4.4**).*

*Note: Cyclic Sense function will not work properly anymore in case of an overcurrent, overtemperature, under- or overvoltage (in case function is selected) event because the respective HS switch will be disabled.*

*Note: When WK1 and WK2 are configured for the alternate measurement function (**WK\_MEAS** = 1) then the wake inputs cannot be selected as wake input sources.*

## System Features

### 5.1.5 SBC Restart Mode

There are multiple reasons to enter the SBC Restart Mode. The purpose of the SBC Restart Mode is to reset the microcontroller:

- in case of undervoltage on VCC1 in SBC Normal and in SBC Stop Mode,
- in case of overvoltage on VCC1 if the bit **VCC1\_OV\_RST** is set and if **CFGP** = '1',
- due to 1st incorrect Watchdog triggering (only if Config1, Config3 or Config 4 is selected, otherwise SBC Fail-Safe Mode is immediately entered),
- In case of a wake event from SBC Sleep or SBC Fail-Safe Mode or a release of overtemperature shutdown (TSD2) out of SBC Fail-Safe Mode this transition is used to ramp up VCC1 after a wake in a defined way.

From SBC Restart Mode, the SBC goes automatically to SBC Normal Mode, i.e the mode is left automatically by the SBC without any microcontroller influence. The SBC **MODE** bits are cleared. As shown in **Figure 52** the Reset Output (RO) is pulled low when entering Restart Mode and is released at the transition to Normal Mode after the reset delay time ( $t_{RD1}$ ). The watchdog timer will start with a long open window starting from the moment of the rising edge of RO and the watchdog period setting in the register **WD\_CTRL** will be changed to the respective default value '100'.

Leaving the SBC Restart Mode will not result in changing / deactivating the Fail outputs.

The behavior of the blocks is listed below:

- All FOx outputs are activated in case of a 1st watchdog trigger failure (if Config1 or Config2 is selected) or in case of VCC1 overvoltage detection (if **VCC1\_OV\_RST** is set)
- VCC1 is ON or ramping up
- VCC2 will be disabled if it was activated before
- VCC3 is fixed or ramping as configured in SBC Normal Mode
- CAN is "woken" due to a wake event or OFF depending on previous SBC and transceiver mode (see also **Chapter 10**). It is wake capable when it was in CAN Normal-, Receive Only or wake capable mode before SBC Restart Mode
- LIN is "woken" or OFF depending on previous SBC and transceiver mode (see also **Chapter 11**). It is wake capable when it was in LIN Normal-, Receive Only or wake capable mode before SBC Restart Mode.
- HS Outputs will be disabled if they were activated before
- RO is pulled low during SBC Restart Mode
- SPI communication is ignored by the SBC, i.e. it is not interpreted
- The Restart Mode entry is signalled in the SPI register **DEV\_STAT** with the bits **DEV\_STAT**

**Table 7 Reasons for Restart - State of SPI Status Bits after Return to Normal Mode**

| Prev. SBC Mode | Event                   | DEV_STAT | WD_FAIL                                      | VCC1_UV | VCC1_OV | VCC1_SC |
|----------------|-------------------------|----------|----------------------------------------------|---------|---------|---------|
| Normal         | 1x Watchdog Failure     | 01       | 01                                           | x       | x       | x       |
| Normal         | 2x Watchdog Failure     | 01       | 10                                           | x       | x       | x       |
| Normal         | VCC1 undervoltage reset | 01       | xx                                           | 1       | x       | x       |
| Normal         | VCC1 overvoltage reset  | 01       | xx                                           | x       | 1       | x       |
| Stop           | 1x Watchdog Failure     | 01       | 01                                           | x       | x       | x       |
| Stop           | 2x Watchdog Failure     | 01       | 10                                           | x       | x       | x       |
| Stop           | VCC1 undervoltage reset | 01       | xx                                           | 1       | x       | x       |
| Stop           | VCC1 overvoltage reset  | 01       | xx                                           | x       | 1       | x       |
| Sleep          | Wake-up event           | 10       | xx                                           | x       | x       | x       |
| Fail-Safe      | Wake-up event           | 01       | see "Reasons for Fail Safe, <b>Table 8</b> " |         |         |         |

## System Features

*Note:* An overvoltage event on VCC1 will only lead to SBC Restart Mode if the bit VCC1\_OV\_RST is set and if **CFGP** = '1' (Config 1/3).

*Note:* The content of the WD\_FAIL bits will depend on the device configuration, e.g. 1 or 2 watchdog failures.

### 5.1.6 SBC Fail-Safe Mode

The purpose of this mode is to bring the system in a safe status after a failure condition by turning off the VCC1 supply and powering off the microcontroller. After a wake event the system is then able to restart again.

The Fail-Safe Mode is automatically reached for following events:

- after an SBC thermal shutdown (TSD2) (see also [Chapter 15.9.3](#)),
- in case of overvoltage on VCC1 if the bit **VCC1\_OV\_RST** is set and if **CFGP** = '0',
- after a 1st incorrect watchdog trigger in Config2 (**CFG** = 1) and after a 2nd incorrect watchdog trigger in Config4 (**CFG** = 0) (see also [Chapter 5.1.1](#)),
- if VCC1 is shorted to GND (see also [Chapter 15.7](#)),
- After 4 consecutive VCC1 undervoltage events (only if  $V_S > V_{S,UV}$ , see [Chapter 15.6](#)).

In this case, the default wake sources (CAN, LINx, WK1...3, see also registers **WK\_CTRL\_2**, **BUS\_CTRL\_1** and **BUS\_CTRL\_2**) are activated, the wake events are cleared in the register **WK\_STAT\_1**, and all output drivers and all voltage regulators are switched off. When WK1 and WK2 are configured for the alternate measurement function (**WK\_MEAS** = 1) then WK1 and WK2 will stay configured for the measurement function when SBC Fail-Safe Mode is entered, i.e. they will not be activated as wake sources.

The SBC Fail-Safe Mode will be maintained until a wake event on the default wake sources occurs. To avoid any fast toggling behavior a filter time of typ. 100ms (**t<sub>FS,min</sub>**) is implemented. Wake events during this time will be stored and will automatically lead to entering SBC Restart Mode after the filter time.

In case of an VCC1 overtemperature shutdown (TSD2) the SBC Restart Mode will be reached automatically after a filter time of typ. 1s (**t<sub>TSD2</sub>**) without the need of a wake event.

Leaving the SBC Fail-Safe Mode will not result in deactivation of the Fail Output pins.

The following functions are influenced during SBC Fail-Safe Mode:

- All FOx outputs are activated (see also [Chapter 14](#))
- VCC1 is OFF
- VCC2 is OFF
- VCC3 is OFF
- CAN is wake capable
- LINx is wake capable
- HS Outputs are OFF
- WK pins are wake capable through static sense (with default 16µs filter time)
- Cyclic sense and Cyclic wake is disabled
- SPI communication is disabled because VCC1 is OFF
- The Fail-Safe Mode activation is signalled in the SPI register **DEV\_STAT** with the bits **FAILURE** and **DEV\_STAT**

## System Features

**Table 8 Reasons for Fail-Safe - State of SPI Status Bits after Return to Normal Mode**

| Prev. SBC Mode | Failure Event        | DEV_STAT | TSD2 | WD_FAIL | VCC1_UV | VCC1_UV_FS | VCC1_OV | VCC1_SC |
|----------------|----------------------|----------|------|---------|---------|------------|---------|---------|
| Normal         | 1 x Watchdog Failure | 01       | x    | 01      | x       | x          | x       | x       |
| Normal         | 2 x Watchdog Failure | 01       | x    | 10      | x       | x          | x       | x       |
| Normal         | TSD2                 | 01       | 1    | xx      | x       | x          | x       | x       |
| Normal         | VCC1 short to GND    | 01       | x    | xx      | 1       | x          | x       | 1       |
| Normal         | 4x VCC1 UV           | 01       | x    | xx      | 1       | 1          | x       | x       |
| Normal         | VCC1 overvoltage     | 01       | x    | xx      | x       | x          | 1       | x       |
| Stop           | 1 x Watchdog Failure | 01       | x    | 01      | x       | x          | x       | x       |
| Stop           | 2 x Watchdog Failure | 01       | x    | 10      | x       | x          | x       | x       |
| Stop           | TSD2                 | 01       | 1    | xx      | x       | x          | x       | x       |
| Stop           | VCC1 short to GND    | 01       | x    | xx      | 1       | x          | x       | 1       |
| Stop           | 4x VCC1 UV           | 01       | x    | xx      | 1       | 1          | x       | x       |
| Stop           | VCC1 overvoltage     | 01       | x    | xx      | x       | x          | 1       | x       |

*Note:* An overvoltage event on VCC1 will only lead to SBC Fail-Safe Mode if the bit VCC1\_OV\_RST is set and if **CFGP** = '0' (Config 2/4).

*Note:* The content of the WD\_FAIL bits will depend on the device configuration, e.g. 1 or 2 watchdog failures.

*Note:* See [Chapter 15.6.1](#) for detailed description of the 4x VCC1 undervoltage behavior.

### 5.1.7 SBC Development Mode

The SBC Development Mode is used during the development phase of the module. It is especially useful for software development.

Compared to the default SBC user mode operation, this mode is a super set of the state machine. The device will start also in SBC Init Mode and it is possible to use all the SBC Modes and functions with following differences:

- Watchdog is stopped and does not need to be triggered. Therefore no reset is triggered due to watchdog failure
- SBC Fail-Safe and SBC Restart Mode are not reached due to watchdog failure but the other reasons to enter these modes are still valid
- LINx, CAN and VCC2 default value in SBC INIT MODE and entering SBC Normal Mode from SBC Init Mode is ON instead of OFF

The SBC Development Mode is reached automatically if the FO3/TEST pin is set and kept LOW during SBC Init Mode. The voltage level monitoring is started as soon as  $VS > V_{POR,f}$ . The Development Mode is configured and maintained if SBC Init Mode is left by sending any SPI command while FO3/TEST is LOW. In case the FO3/TEST level will be HIGH for longer than  $t_{TEST}$  during the monitoring period then the SBC Development Mode is not reached.

The SBC will remain in this mode for all conditions and can only be left by powering down the device ( $VS < V_{POR,f}$ ).

---

## System Features

*Note: The absolute maximum ratings of the pin FO3/TEST must be observed. To increase the robustness of this pin during debugging or programming a series resistor between FO3/TEST and the connector can be added (see [Figure 66](#)).*

## System Features

### 5.2 Wake Features

Following wake sources are implemented in the device:

- Static Sense: WK inputs are permanently active (see [Chapter 12](#))
- Cyclic Sense: WK inputs only active during on-time of cyclic sense period (see below)
- Cyclic Wake: internal wake source controlled via internal timer (see below)
- CAN wake: Wake-up via CAN message (see [Chapter 10](#))
- LIN wake: Wake-up via LIN message (see [Chapter 11](#))

#### 5.2.1 Cyclic Sense

The cyclic sense feature is intended to reduce the quiescent current of the device and the application. In the cyclic sense configuration, one or more high-side drivers are switched on periodically controlled by [TIMER1\\_CTRL](#) and [TIMER2\\_CTRL](#). The respective high-side drivers supply external circuitries e.g. switches and/or resistor arrays, which are connected to one or more wake inputs (see [Figure 5](#)). Any edge change of the WKx input signal during the on-time of the cyclic sense period causes a wake. Depending on the SBC mode, either the INT is pulled low (SBC Normal Mode and Stop Mode) or the SBC is woken enabling the VCC1 (after SBC Sleep and SBC Fail-Safe Mode).

**Figure 5 Cyclic Sense Working Principle**

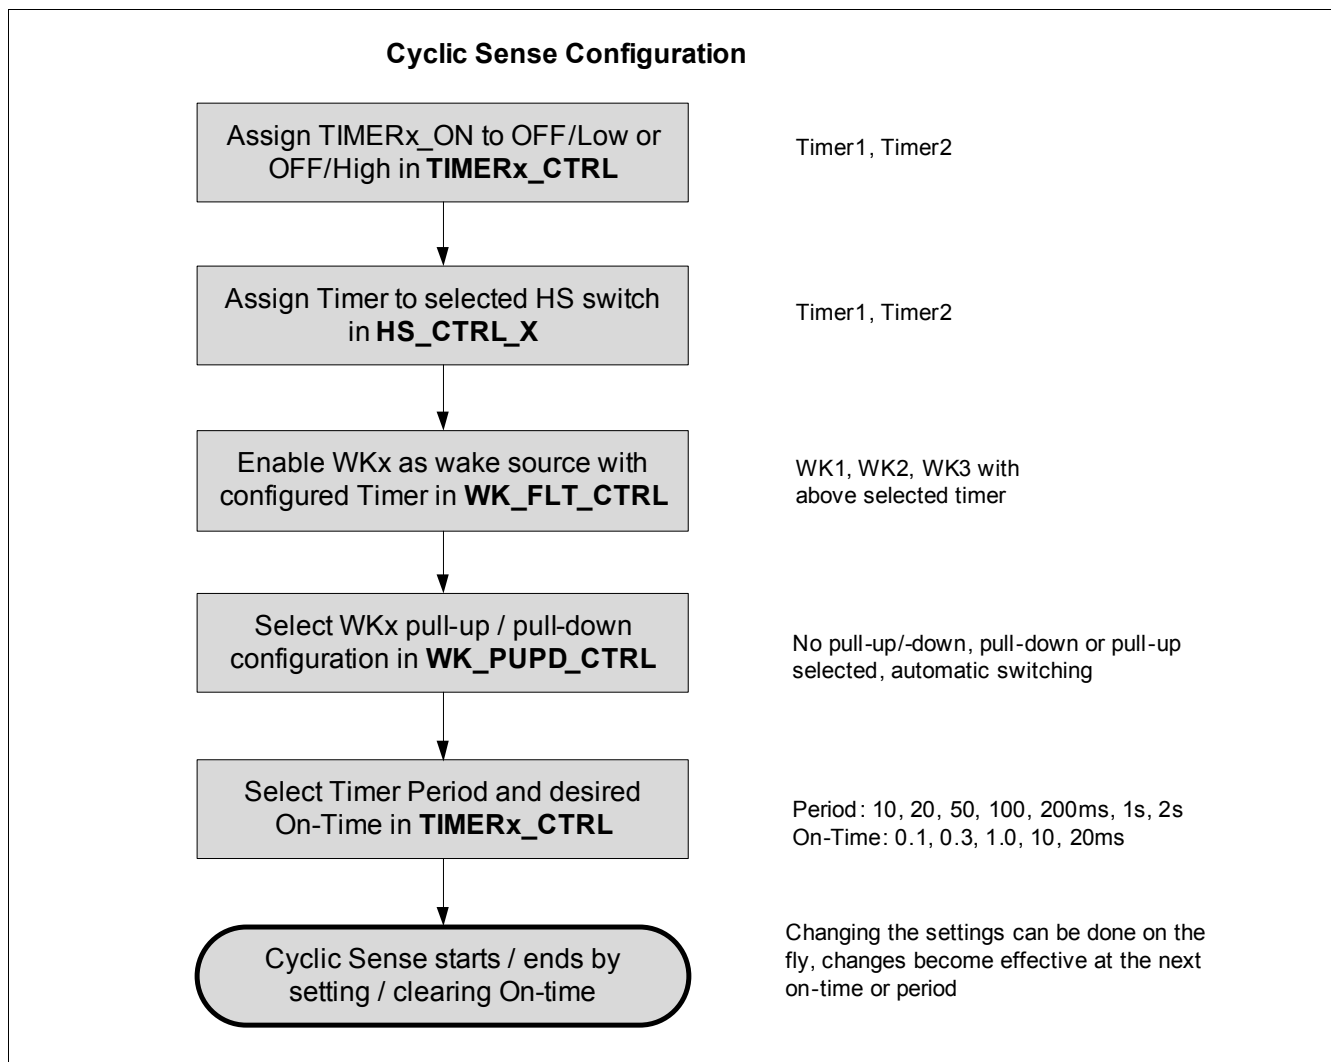

## System Features

### 5.2.1.1 Configuration and Operation of Cyclic Sense

The correct sequence to configure the cyclic sense is shown in [Figure 6](#). All the configurations have to be performed before the on-time is set in the `TIMERx_CTRL` registers. The settings “OFF / LOW” and “OFF / HIGH” define the voltage level of the respective HS driver before the start of the cyclic sense. The intention of this selection is to avoid an unintentional wake due to a voltage level change at the start of the cyclic sense.

Cyclic Sense (=TimerX) will start as soon as the respective on-time has been selected independently from the assignment of the HS and filter configuration. The selection of the respective timer (Config C/D see [Chapter 12.2.1](#)) must therefore be done before starting the timer. The correct configuration sequence is as follows:

- Configure the initial level
- Mapping of a Timer to the respective HSx outputs
- Configuring the respective filter timing and WK pins
- Configuring the timer period and on-time

**Figure 6 Cyclic Sense: Configuration and Sequence**

**Note:** All configurations of period and on-time can be selected. However, recommended on-times for cyclic sense are 0.1ms, 0.3ms and 1ms. The `SPI_FAIL` will be set if the on-time is longer than the period.

---

## System Features

The first sample of the WK input value (HIGH or LOW) is taken as the reference for the next cycle. A change of the WK input value between the first and second cycle recognized during the on-time of the second cycle will cause a wake from SBC Sleep Mode or an interrupt during SBC Normal or SBC Stop Mode.

A filter time of 16µs is implemented to avoid a parasitic wake-up due to transients or EMC disturbances. The filter time  $t_{FWK1}$  is triggered right at the end of the selected on-time and a wake signal is recognized if:

- the input level will not cross the switching threshold level of typ. 3V during the selected filter time (i.e. if the signal will keep the HIGH or LOW level) and
- there was an input level change between the current and previous cycle

## System Features

A wake event due to cyclic sense will set the respective bit WK1\_WU, WK2\_WU, or WK3\_WU.

During Cyclic Sense, **WK\_LVL\_STAT** is updated only with the sampled voltage levels of the WKx pins in SBC Normal or SBC Stop Mode.

The functionality of the sampling and different scenarios are depicted in **Figure 7** to **Figure 9**. The behavior in SBC Stop and SBC Sleep Mode is identical except that in Stop Mode INT will be triggered to signal a change of WK input levels and in SBC Sleep Mode, VCC1 will power-up instead.

**Figure 7** Wake Input Timing

**Figure 8** Cyclic Sense Example in SBC Stop Mode, HSx starts “OFF”/LOW, GND based WKx input

## System Features

**Figure 9** Cyclic Sense Example in SBC Sleep Mode, HSx starts “OFF”/HIGH, GND based WKx input

The cyclic sense function will not work properly anymore in case of following conditions:

- in case SBC Fail-Safe Mode is entered: The respective HS Switch will be disabled and the respective wake pin will be changed to static sensing
- In SBC Normal, Stop, or Sleep Mode in case of an overcurrent, overtemperature, under- or overvoltage (in case function is selected) event: the respective HS switch will be disabled

**Note:** The internal timers for cyclic sense are not disabled automatically in case the HS switch is turned off due to above mentioned failures. This must be considered to avoid loss of wake events.

### 5.2.1.2 Cyclic Sense in Low Power Mode

If cyclic sense is intended for SBC Stop or SBC Sleep Mode mode, it is necessary to activate the cyclic sense in SBC Normal Mode before going to the low power mode. A wake event due to cyclic sense will set the respective bit WK1\_WU, WK2\_WU or WK3\_WU. In Stop Mode the wake event will trigger an interrupt, in Sleep Mode the wake event will send the device via Restart Mode to Normal Mode. Before returning to SBC Sleep Mode, the wake status register **WK\_STAT\_1** and **WK\_STAT\_2** needs to be cleared. Trying to go to SBC Sleep mode with uncleared wake flags, such as WKx\_WU the SBC will directly wake-up from Sleep Mode by going via Restart Mode to Normal Mode, a reset is issued. The WKx\_WU bit is seen as source for the wake. This is implemented in order not to loose an wake event during the transition.

## System Features

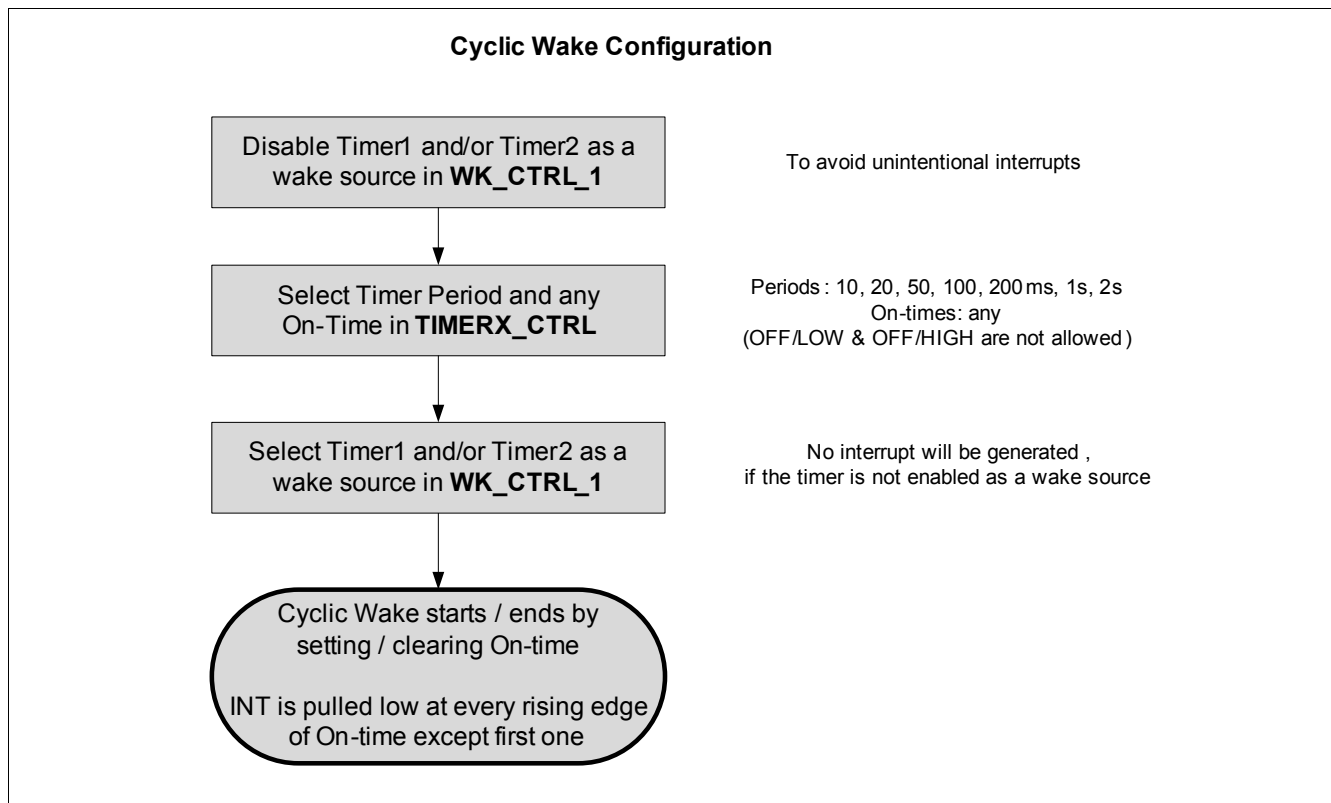

### 5.2.2 Cyclic Wake

The cyclic wake feature is intended to reduce the quiescent current of the device and application.

For the cyclic wake feature one or both timers are configured as internal wake-up source and will periodically trigger an interrupt in SBC Normal and SBC Stop Mode.

The correct sequence to configure the cyclic wake is shown in **Figure 10**. The sequence is as follows:

- First, disable the timers to ensure that there is not unintentional interrupt when activating cyclic wake,
- Enable Timer1 and/or Timer2 as a wake-up source in the register **WK\_CTRL\_1**,
- Configure the respective period Timer1 and/or Timer2. Also an on-time (any value) must be selected to start the cyclic wake even if the value is ignored.

**Figure 10 Cyclic Wake: Configuration and Sequence**

As in cyclic sense, the cyclic wake function will start as soon as the on-time is configured. An interrupt is generated for every start of the on time except for the very first time when the timer is started

---

## System Features

### 5.2.3 Internal Timer

The integrated Timer1 and Timer2 are typically used to wake up the microcontroller periodically (cyclic wake) or to perform cyclic sense on the wake inputs. Therefore, the timers can be mapped to the dedicated HS switches by SPI (via [HS\\_CTRL1...2](#)).

Following periods and on-times can be selected via the register [TIMER1\\_CTRL](#) and [TIMER2\\_CTRL](#) respectively:

- Period: 10ms / 20ms / 50ms / 100ms / 200ms / 1s / 2s
- On time: 0.1ms / 0.3ms / 1.0ms / 10ms / 20ms / OFF at HIGH or LOW

### 5.3 Supervision Features

The device offers various supervision features to support functional safety requirements. Please see [Chapter 15](#) for more information.

## 5.4 Partial Networking on CAN

### 5.4.1 CAN Partial Networking - Selective Wake Feature

The CAN Partial Networking feature can be activated for SBC Normal Mode, in SBC Sleep Mode and in SBC Stop Mode. For SBC Sleep Mode the Partial Networking has to be activated before sending the SBC to Sleep Mode. For SBC Stop Mode the Partial Networking has to be activated before going to SBC Stop Mode.

There are 2 detection mechanism available

- WUP (Wake-Up Pattern) this is a CAN wake, that reacts on the CAN dominant time, with 2 dominant signals as defined in ISO 11898-2:2016.
- WUF (Wake-Up frame) this is the wake-up on a CAN frame that matches the programmed message filter configured in the SBC via SPI.

The default baudrate is set to 500kBaud. Besides the commonly used baudrates of 125kBaud and 250kBaud, other baudrates up to 1MBaud can be selected (see [Chapter 16.5.2](#) and [Chapter 16.5.3](#) for more details).

5.4.2 SBC Partial Networking Function

The CAN Partial Networking Modes are shown in this figure.

Figure 11 CAN Selective Wake State Diagram

### 5.4.2.1 Activation of SWK

Below figure shows the principal of the SWK activation.

**Figure 12** Flow for activation of SWK

### 5.4.2.2 Wake-up Pattern (WUP)

A WUP is signaled on the bus by two consecutive dominant bus levels for at least  $t_{Wake1}$ , each separated by a recessive bus level.

**Figure 13 WUP detection following the definition in ISO 11898-2:2016**

### 5.4.2.3 Wake-up Frame (WUF)

The wake-up frame detection is implemented as defined in ISO 11898-2:2016.

Only CAN frames according ISO11899-1 are considered as potential wake-up frames.

A bus wake-up shall be performed, if selective wake-up function is enabled and a "valid WUF" has been received. The transceiver may ignore up to four consecutive CAN data frames that start after switching on the bias.

A received frame is a "valid WUF" in case all of the following conditions are met:

- The ID of the received frame is exactly matching a configured ID in the relevant bit positions. The relevant bit positions are given by an ID mask. The ID and the ID mask might have either 11 bits or 29 bits.
- The DLC of the received frame is exactly matching the configured DLC.

- In case DLC is greater than 0, the data field of the received frame has at least one bit set in a bit position, where also in the configured data mask in the corresponding bit position the bit is set.
- No error exists according to ISO 11898-1 excepting errors which are signalled in the ACK field and EOF field.

#### 5.4.2.4 CAN Protocol Error Counter

The counter is incremented, when a bit stuffing, CRC or form error according to ISO11898-1 is detected. If a frame has been received that is valid up to the end of the CRC field and the counter is not zero, the counter is decremented.

If the counter has reached a value of 31, the following actions is performed on the next increment of this counter:

- The selective wake function is disabled,
- the CAN transceiver is woken,
- SYSERR is set and the error counter value = 32 can be read.

On each increment or decrement of the counter the decoder unit waits for at least 6 and most 10 recessive bits before considering a dominant bit as new start of frame.

The error counter is enabled:

- whenever the CAN is in Normal Mode, Receive Only Mode or in WUF detection state.

The error counter is cleared under the following conditions:

- at the transition from WUF detection to WUP detection 1 (after  $t_{\text{SILENCE}}$  expiration, while SWK is correctly enabled)
- When WUF detection state is entered (in this way the counter will start from 0 when SWK is enabled)
- At SBC or CAN rearming (when exiting the woken state)
- When the CAN Mode bits are selected '000', '100' (CAN OFF) or 0'01' (Wake capable without SWK function enabled)
- While CAN\_FD\_EN = '1' and DIS\_ERR\_CNT = '1'  
(the counter is cleared and stays cleared when these two bits are set in the SPI registers)

The Error Counter is frozen:

- after a wake-up being in woken state

The counter value can be read out of the bits **ECNT**.

### 5.4.3 Diagnoses Flags

#### 5.4.3.1 PWRON/RESET-FLAG

The power-on reset can be detected and read by the **POR** bit in the SBC Status register. The VS power on resets all register in the SBC to reset value. SWK is not configured.

#### 5.4.3.2 BUSERR-Flag

Bus Dominant Time-out detection is implemented and signaled by CAN\_Fail\_x in register **BUS\_STAT\_1**.

#### 5.4.3.3 TXD Dominant Time-out flag

TXD Dominant timeout is shown in the SPI bit CAN\_FAIL\_x in register **BUS\_STAT\_1**.

#### 5.4.3.4 WUP Flag

The WUP bit in the **SWK\_STAT** register shows that a Wake-Up Pattern (WUP) has caused a wake of the CAN transceiver. It can also indicate an internal mode change from WUP detection 1 state to WUF detection after a valid WUP.

In the following case the bit is set:

- SWK is activated: due to  $t_{\text{SILENCE}}$ , the CAN changes into the state WUP detection 1. If a WUP is detected in this state, then the **WUP** bit is set
- SWK is deactivated: the **WUP** bit is set if a WUP wakes up the CAN. In addition, the **CAN\_WU** bit is set.
- in case WUP is detected during WUP detection 2 state (after a SYSERR) the bits **WUP** and **CAN\_WU** are set

The **WUP** bit is cleared automatically by the SBC at the next rearming of the CAN transceiver.

*Note: It is possible that WUF and WUP bit are set at the same time if a WUF causes a wake out of SWK, by setting the interrupt or by restart out of SBC Sleep Mode. The reason is because the CAN has been in WUP detection 1 state during the time of SWK mode (because of  $t_{\text{SILENCE}}$ ). See also **Figure 11**.*

#### 5.4.3.5 WUF Flag (WUF)

The WUF bit in the **SWK\_STAT** register shows that a Wake-Up frame (WUF) has caused a wake of the CAN block. In SBC Sleep Mode this wake causes a transition to SBC Restart Mode, in SBC Normal Mode and in SBC Stop Mode it causes an interrupt. Also in case of this wake the bit **CAN\_WU** in the register **WK\_STAT\_1** is set.

The **WUF** bit is cleared automatically by the SBC at the next rearming of the CAN SWK function.

#### 5.4.3.6 SYSERR Flag (SYSERR)

The bit SYSERR is set in case of an configuration error and in case of an error counter overflow. The bit is only updated (set to '1') if a CAN mode with SWK is enabled via CAN\_x. If **INT\_GLOBAL** is set, then an interrupt is triggered on INTN every time **SYSERR** is set.

When programming selective wake via CAN\_x, SYSERR = '0' signals that the SWK function has been enabled. The bit can be cleared via SPI. The bit is '0' after Power on Reset of the SBC.

#### 5.4.3.7 Configuration Error

A configuration error sets the SYSERR bit to '1'. When enabling SWK via the bits CAN\_x a config check is done. If the check is successful SWK is enabled, the bit SYSERR is set to '0'. In SBC Normal Mode it is also possible to

detect a Configuration Error while SWK is enabled. This will occur if the **CFG\_VAL** bit is cleared, e.g. by changing the SWK registers (from address 010 0001 to address 011 0011). In SBC Stop Mode and SBC Sleep Mode this is not possible as the SWK registers can not be changed.

Configuration Check:

in SBC Restart Mode, the **CFG\_VAL** bit is cleared by the SBC. If the SBC Restart Mode was not triggered by a WUF wake up from SBC Sleep Mode and the CAN was with SWK enabled, then the **SYSERR** bit will be set.

The **SYSERR** bit has to be cleared by the microcontroller.

The **SYSERR** bit cannot be cleared when **CAN\_2** is '1' and below conditions occur:

- Data valid bit not set by microcontroller, i.e. **CFG\_VAL** is not set to '1'. The **CFG\_VAL** bit is reset after SWK wake and needs to be set by the microcontroller before activation SWK again.
- **CFG\_VAL** bit reset by the SBC when data are changed via SPI programming. (Only possible in SBC Normal Mode)

*Note: The SWK configuration is still valid if only the **SWK\_CTRL** register is modified.*

#### 5.4.3.8 CAN Bus Timeout-Flag (**CANTO**)

In CAN WUF detection and CAN WUP detection 2 state the bit **CANTO** is set to '1' if the time  $t_{\text{SILENCE}}$  expires. The bit can be cleared by the microcontroller. If the interrupt function for **CANTO** is enabled then an interrupt is generated in SBC Stop or SBC Normal Mode when the **CANTO** set to '1'. The interrupt is enabled by setting the bit **CANTO\_MASK** to '1'. Each **CANTO** event will trigger a interrupt even if the **CANTO** bit is not cleared.

There is no wake out of SBC Sleep Mode because of CAN time-out.

#### 5.4.3.9 CAN Bus Silence-Flag (**CANSIL**)

In CAN WUF detection and CAN WUP detection 2 state the bit **CANSIL** is set to '1' if the time  $t_{\text{SILENCE}}$  expires. The **CANSIL** bit is set back to '0' with a WUP. With this bit the microcontroller can monitor if there is activity on the CAN bus while being in SWK Mode. The bit can be read in SBC Stop and SBC Normal Mode.

#### 5.4.3.10 SYNC-FLAG (**SYNC**)

The bit **SYNC** shows that SWK is working and synchronous to the CAN bus. To get a **SYNC** bit set it is required to enable the CAN to CAN Normal or in Receive Only Mode or in WUF detection. It is not required to enable the CAN SWK Mode.

The bit is set to '1' if a valid CAN frame has been received (no CRC error and no stuffing error). It is set back to '0' if a CAN protocol error is detected. When switching into SWK mode the **SYNC** bit indicates to the microcontroller that the frame detection is running and the next CAN frame can be detected as a WUF, CAN wake-up can now be handled by the SBC. It is possible to enter a SBC low-power mode with SWK even if the bit is not set to '1', as this is necessary in case of a silent bus.

#### 5.4.3.11 SWK\_SET FLAG (**SWK\_SET**)

The **SWK\_SET** bit is set to signalize the following states (see also **Figure 11**):

- when SWK was correctly enabled in WUF Detection state,
- when SWK was correctly enabled when in WUP Detection 1 state,
- after a **SYSERR** before a wake event in WUP Detection 2 state,

The bit is cleared under following conditions:

- after a wake-up (ECNT overflow, WUP in WUP detection 2, WUF in WUF detection)
- if CAN\_2 is cleared

#### 5.4.4 SBC Modes for Selective Wake (SWK)

The SBC mode is selected via the **MODE** bits as described in [Chapter 5.1](#).

The mode of the CAN transceiver needs to be selected in SBC Normal Mode. The CAN mode is programmed the bits CAN\_0, CAN\_1 and CAN\_2. In the low-power modes (SBC Stop, SBC Sleep) the CAN mode can not be changed via SPI.

The detailed SBC state machine diagram including the CAN selective wake feature is shown in [Figure 6](#).

The application must now distinguish between the normal CAN operation and the selective wake function:

- WK Mode: This is the normal CAN wake capable mode without the selective wake function
- SWK Mode: This is the CAN wake capable mode with the selective wake function enabled

[Figure 14](#) shows the possible CAN transceiver modes.

**Figure 14** CAN SWK State Diagram

##### 5.4.4.1 SBC Normal Mode with SWK

In SBC Normal Mode the CAN Transceiver can be switched into the following CAN Modes

- CAN OFF
- CAN WK Mode (without SWK)
- CAN SWK Mode
- CAN Receive Only (No SWK activated)
- CAN Receive Only Mode with SWK
- CAN Normal Mode (No SWK activated)
- CAN Normal Mode with SWK

In the CAN Normal Mode with SWK the CAN Transceiver works as in SBC Normal Mode, so bus data is received through RXD, data is transmitted through TXD and sent to the bus. In addition the SWK block is active. It

monitors the data on the CAN bus, updates the error counter and sets the **CANSIL** flag if there is no communication on the bus.

It will generate an CAN Wake interrupt in case a WUF is detected (RXD is not pulled to LOW in this configuration).

In CAN Receive Only Mode with SWK, CAN data can be received on RXD and SWK is active, no data can be sent to the bus.

The bit **SYSERR** = '0' indicates that the SWK function is enabled, and no frame error counter overflow is detected.

**Table 9 CAN Modes selected via SPI in SBC Normal Mode**

| CAN Mode                  | CAN_2 | CAN_1 | CAN_0 |
|---------------------------|-------|-------|-------|
| CAN OFF                   | 0     | 0     | 0     |
| CAN WK Mode (no SWK)      | 0     | 0     | 1     |
| CAN Receive Only (no SWK) | 0     | 1     | 0x    |
| CAN Normal Mode (no SWK)  | 0     | 1     | 1     |
| CAN OFF                   | 1     | 0     | 0     |
| CAN SWK Mode              | 1     | 0     | 1     |
| CAN Receive Only with SWK | 1     | 1     | 0     |
| CAN Normal Mode with SWK  | 1     | 1     | 1     |

When reading back CAN\_x the programmed mode is shown in SBC Normal Mode. To read the real CAN mode the bits **SYSERR**, **SWK\_SET** and **CAN** have to be evaluated. A change out of SBC Normal Mode can change the CAN\_0 and CAN\_1 bits.

#### 5.4.4.2 SBC Stop Mode with SWK

In SBC Stop Mode the CAN Transceiver can be operated with the following CAN Modes

- CAN OFF
- CAN WK Mode (no SWK)
- CAN SWK Mode
- CAN Receive Only (no SWK)
- CAN Receive Only with SWK
- CAN Normal Mode (no SWK)
- CAN Normal Mode with SWK

To enable CAN SWK Mode the CAN has to be switched to "CAN Normal Mode with SWK", "CAN Receive Only Mode with SWK" or to "CAN SWK Mode" in SBC Normal Mode before sending the SBC to SBC Stop Mode. The bit **SYSERR** = '0' indicates that the SWK function is enabled. The table shows the change of CAN Mode when switching from SBC Normal Mode to SBC Stop Mode.

*Note: CAN Receive Only Mode in SBC Stop Mode is implemented to also enable pretended networking (Partial networking done in the microcontroller).*

**Table 10** CAN Modes change when switching from SBC Normal Mode to SBC Stop Mode

| Programmed CAN Mode in SBC Normal Mode | CAN_x bits | SYSERR bit | CAN Mode in SBC Stop Mode | CAN_x bits |
|----------------------------------------|------------|------------|---------------------------|------------|
| CAN OFF                                | 000        | 0          | CAN OFF                   | 000        |
| CAN WK Mode (no SWK)                   | 001        | 0          | CAN WK Mode (no SWK)      | 001        |
| CAN Receive Only (no SWK)              | 010        | 0          | CAN Receive Only (no SWK) | 010        |
| CAN Normal Mode (no SWK)               | 011        | 0          | CAN WK Mode (no SWK)      | 011        |
| CAN OFF                                | 100        | 0          | CAN OFF                   | 100        |
| CAN SWK Mode                           | 101        | 0          | CAN SWK Mode              | 101        |
| CAN SWK Mode                           | 101        | 1          | CAN WK Mode (no SWK)      | 101        |
| CAN Receive Only with SWK              | 110        | 0          | CAN Receive Only with SWK | 110        |
| CAN Receive Only with SWK              | 110        | 1          | CAN Receive Only (no SWK) | 110        |
| CAN Normal Mode with SWK               | 111        | 0          | CAN Normal Mode with SWK  | 111        |
| CAN Normal Mode with SWK               | 111        | 1          | CAN Normal Mode (no SWK)  | 111        |

*Note:* When SYSERR is set then WUF frames will not be detected, i.e. the selective wake function is not activated (no SWK), but the MSB of CAN mode is not changed in the register.

#### 5.4.4.3 SBC Sleep Mode with SWK

In SBC Sleep Mode the CAN Transceiver can be switched into the following CAN Modes

- CAN OFF
- CAN WK Mode (without SWK)
- CAN SWK Mode

To enable “CAN SWK Mode” the CAN has to be switched to “CAN Normal Mode with SWK”, “CAN Receive Only Mode with SWK” or to “CAN SWK Mode” in SBC Normal Mode before sending the device to SBC Sleep Mode. The table shows the change of CAN mode when switching from SBC Normal Mode to Sleep Mode.

A wake from Sleep Mode with Selective Wake (Valid WUF) leads to Restart Mode. In Restart Mode the CFG\_VAL bit will be cleared by the SBC, the SYSERR bit is not set. In the register CAN\_x the programmed CAN SWK Mode (101) can be read.

To enable the CAN SWK Mode again and to enter SBC Sleep Mode the following sequence can be used; Program a CAN Mode different from CAN SWK Mode (101, 110, 111), set the CFG\_VAL, CLEAR SYSERR bit, Set CAN\_x bits to CAN SWK Mode (101), switch SBC to Sleep Mode.

To enable the CAN WK Mode or CAN SWK Mode again after a wake on CAN a rearming is required for the CAN transceiver to be wake capable again. The rearming is done by programming the CAN into a different mode with the CAN\_x bit and back into the CAN WK Mode or CAN SWK Mode. To avoid lock-up when switching the SBC into Sleep Mode with an already woken CAN transceiver, the SBC does an automatic rearming of the CAN transceiver when switching into Sleep Mode. So after switching into Sleep Mode the CAN transceiver is either in CAN SWK Mode or CAN WK Mode depending on CAN\_x setting and SYSERR bit (If CAN is switched to OFF Mode it is also OFF in Sleep Mode)

**Table 11** CAN Modes change when switching to SBC Sleep Mode

| Programmed CAN Mode in SBC Normal Mode | CAN_x bits | SYSERR bit | CAN Mode in SBC Sleep Mode | CAN_x bits |
|----------------------------------------|------------|------------|----------------------------|------------|
| CAN OFF                                | 000        | 0          | CAN OFF                    | 000        |
| CAN WK Mode (no SWK)                   | 001        | 0          | CAN WK Mode (no SWK)       | 001        |
| CAN Receive Only (no SWK)              | 010        | 0          | CAN WK Mode (no SWK)       | 001        |
| CAN Normal Mode (no SWK)               | 011        | 0          | CAN WK Mode (no SWK)       | 001        |
| CAN OFF                                | 100        | 0          | CAN OFF                    | 100        |
| CAN SWK Mode                           | 101        | 0          | CAN SWK Mode               | 101        |
| CAN SWK Mode                           | 101        | 1          | CAN WK Mode (no SWK)       | 101        |
| CAN Receive Only with SWK              | 110        | 0          | CAN SWK Mode               | 101        |
| CAN Receive Only with SWK              | 110        | 1          | CAN WK Mode (no SWK)       | 101        |
| CAN Normal Mode with SWK               | 111        | 0          | CAN SWK Mode               | 101        |
| CAN Normal Mode with SWK               | 111        | 1          | CAN WK Mode (no SWK)       | 101        |

#### 5.4.4.4 SBC Restart Mode with SWK

If SBC Restart Mode is entered the transceiver can change the CAN mode. During Restart or after Restart the following modes are possible

- CAN OFF
- CAN WK Mode (either still wake cable or already woken up)
- CAN SWK Mode (WUF Wake from Sleep)

**Table 12** CAN Modes change in case of Restart out of SBC Normal Mode

| Programmed CAN Mode in SBC Normal Mode | CAN_x bits | SYSERR bit | CAN Mode in and after SBC Restart Mode | CAN_x bits | SYSERR bit |
|----------------------------------------|------------|------------|----------------------------------------|------------|------------|
| CAN OFF                                | 000        | 0          | CAN OFF                                | 000        | 0          |
| CAN WK Mode (no SWK)                   | 001        | 0          | CAN WK Mode (no SWK)                   | 001        | 0          |
| CAN Receive Only (no SWK)              | 010        | 0          | CAN WK Mode (no SWK)                   | 001        | 0          |
| CAN Normal Mode (no SWK)               | 011        | 0          | CAN WK Mode (no SWK)                   | 001        | 0          |
| CAN OFF                                | 100        | 0          | CAN OFF                                | 100        | 0          |
| CAN SWK Mode                           | 101        | 0          | CAN WK Mode (no SWK)                   | 101        | 1          |
| CAN SWK Mode                           | 101        | 1          | CAN WK Mode (no SWK)                   | 101        | 1          |
| CAN Receive Only with SWK              | 110        | 0          | CAN WK Mode (no SWK)                   | 101        | 1          |
| CAN Receive Only with SWK              | 110        | 1          | CAN WK Mode (no SWK)                   | 101        | 1          |
| CAN Normal Mode with SWK               | 111        | 0          | CAN WK Mode (no SWK)                   | 101        | 1          |
| CAN Normal Mode with SWK               | 111        | 1          | CAN WK Mode (no SWK)                   | 101        | 1          |

The various reasons for entering SBC Restart Mode and the respective status flag settings are shown in [Table 13](#).

**Table 13 CAN Modes change in case of Restart out of SBC Sleep Mode**

| CAN Mode in SBC Sleep Mode      | CAN Mode in and after SBC Restart Mode | CAN_x | SYS ERR | CAN_WU | WUP               | WUF | ECNT_x | Reason for Restart                           |
|---------------------------------|----------------------------------------|-------|---------|--------|-------------------|-----|--------|----------------------------------------------|
| CAN OFF                         | CAN OFF                                | 000   | 0       | 0      | 0                 | 0   | 0      | Wake on other wake source                    |
| CAN WK Mode                     | CAN woken up                           | 001   | 0       | 1      | 1                 | 0   | 0      | Wake (WUP) on CAN                            |
| CAN WK Mode                     | CAN WK Mode                            | 001   | 0       | 0      | 0                 | 0   | 0      | Wake on other wake source                    |
| CAN SWK Mode                    | CAN woken up                           | 101   | 0       | 1      | 0/1 <sup>1)</sup> | 1   | x      | Wake (WUF) on CAN                            |
| CAN SWK Mode,                   | CAN woken up                           | 101   | 1       | 1      | 0/1 <sup>2)</sup> | 0   | 100000 | Wake due to error counter overflow           |
| CAN SWK selected, CAN WK active | CAN woken up.                          | 101   | 1       | 1      | 1                 | 0   | 0      | Wake (WUP) on CAN, config check was not pass |
| CAN SWK Mode                    | CAN WK Mode                            | 101   | 1       | 0      | 0/1               | 0   | x      | Wake on other wake source                    |

- 1) In case there is a WUF detection within  $t_{\text{SILENCE}}$  then the WUP bit will not be set. Otherwise it will always be set together with the WUF bit.
- 2) In some cases the WUP bit might stay cleared even after  $t_{\text{SILENCE}}$ , e.g. when the error counter expires without detecting a wake up pattern

#### 5.4.4.5 SBC Fail-Safe Mode with SWK

When SBC Fail-Safe Mode is entered the CAN transceiver is automatically set into WK Mode (wake capable) without the selective wake function.

#### 5.4.5 Wake-up

A wake-up via CAN leads to a restart out of SBC Sleep Mode and to an interrupt in SBC Normal Mode, and in SBC Stop Mode. After the wake event the bit CAN\_WU is set, and the details about the wake can be read out of the bits WUP, WUF, SYSERR, and ECNT.

#### 5.4.6 Configuration for SWK

The CAN protocol handler settings can be configured in following registers:

- **SWK\_BTL1\_CTRL** defines the number of time quanta in a bit time. This number depends also on the internal clock settings performed in the register **SWK\_CDR\_CTRL2**;
- **SWK\_BTL2\_CTRL** defines the sampling point position;
- The respective receiver during frame detection mode can be selected via the bit **RX\_WK\_SEL**;
- The clock and data recovery (see also **Chapter 5.4.8**) can be configured in the registers **SWK\_CDR\_CTRL1**, **SWK\_CDR\_CTRL2**, **SWK\_CDR\_LIMIT\_HIGH\_CTRL** and **SWK\_CDR\_LIMIT\_LOW\_CTRL**;

The actual configuration for selective wake is done via the Selective Wake Control Registers SWK\_IDx\_CTRL, SWK\_MASK\_IDx\_CTRL, SWK\_DLC\_CTRL, SWK\_DATAx\_CTRL.

The oscillator has the option to be trimmed by the microcontroller. To measure the oscillator, the SPI bit OSC\_CAL needs to be set to 1 and a defined pulse needs to be given to the TXDCAN pin by the microcontroller (e.g. 1µs pulse, CAN needs to be switched off before). The SBC measures the length of the pulse by counting the time with the integrated oscillator. The counter value can be read out of the register SWK\_OSC\_CAL\_H\_STATE and SWK\_OSC\_CAL\_L\_STATE. To change the oscillator the trimming function needs to be enabled by setting the bits TRIM\_EN\_x = 11 (and OSC\_CAL = 1). The oscillator can then be adjusted by writing into the registers **SWK\_OSC\_TRIM\_CTRL** and **SWK\_OPT\_CTRL**. To finish the trimming, the bits TRIM\_EN\_x need to be set back to "00".

### 5.4.7 CAN Flexible Data Rate (CAN FD) Tolerant Mode

The CAN FD tolerant mode can be activated by setting the bit **CAN\_FD\_EN** = '1' in the register **SWK\_CAN\_FD\_CTRL**. With this mode the internal CAN frame decoding will be stopped for CAN FD frame formats:

- The high baudrate part of a CAN FD frame will be ignored,
- No Error Handling (Bit Stuffing, CRC checking, Form Errors) will be applied to remaining CAN frame fields (Data Field, CRC Field, ...),
- No wake up is done on CAN FD frames.

The internal CAN frame decoder will be ready for new CAN frame reception when the End of frame (EOF) of a CAN FD frame is detected. The identification for a CAN FD frame is based on the EDL Bit, which is sent in the Control Field of a CAN FD frame:

- EDL Bit = 1 identifies the current frame as an CAN FD frame and will stop further decoding on it.
- EDL Bit = 0 identifies the current frame as CAN 2.0 frame and processing of the frame will be continued

In this way it is possible to send mixed CAN frame formats without affecting the selective wake functionality by error counter increment and subsequent misleading wake up. In addition to the **CAN\_FD\_EN** bit also a filter setting must be provided for the CAN FD tolerant mode. This filter setting defines the minimum dominant time for a CAN FD dominant bit which will be considered as a dominant bit from the CAN FD frame decoder. This value must be aligned with the selected high baudrate of the data field in the CAN network.

To support programming via CAN during CAN FD mode a dedicated SPI bit **DIS\_ERR\_CNT** is available to avoid an overflow of the implemented error counter (see also **Chapter 5.4.2.4**).

The behavior of the error counter depends on the setting of the bits **DIS\_ERR\_CNT** and **CAN\_FD\_EN** and is shown in the table below:

**Table 14 Error Counter Behavior**

| <b>DIS_ERR_CNT</b> setting | <b>CAN_FD_EN</b> setting | <b>Error Counter Behavior</b>                                                                                                                                                     |
|----------------------------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                          | 0                        | Error Counter counts up when a CAN FD frame or an incorrect/corrupted CAN frame is received; counts down when a CAN frame is received properly (as specified in ISO 11898-2:2016) |
| 1                          | 0                        | Error Counter counts up when a CAN FD frame or an incorrect/corrupted CAN frame is received; counts down when a CAN frame is received properly (as specified in ISO 11898-2:2016) |
| 0                          | 1                        | Error Counter counts down when correct CAN (incl. CAN FD) frame is received                                                                                                       |
| 1                          | 1                        | Error Counter is and stays cleared to avoid an overflow during programming via CAN                                                                                                |

The **DIS\_ERR\_CNT** bit is automatically cleared at  $t_{\text{SILENCE}}$  expiration.

### 5.4.8 Clock and Data Recovery

In order to compensate possible deviations on the CAN oscillator frequency caused by assembly and lifetime effects, the device features an integrated clock and data recovery (CDR).

It is recommended to always enable the CDR feature during SWK operation.

#### 5.4.8.1 Configuring the Clock Data Recovery for SWK

The Clock and Data Recovery can be optionally enabled or disabled with the **CDR\_EN** bit in the **SWK\_CDR\_CTRL1** SPI register. In case the feature is enabled, the CAN bit stream will be measured and the internal clock used for the CAN frame decoding will be updated accordingly.

Before the Clock and Data Recovery can be used it must be configured properly related to the used baud rate and filtering characteristics (see [Chapter 5.4.8.2](#)).

It is strongly recommended not to enable/disable the Clock Recovery during a active CAN Communication.

To ensure this, it is recommended to enable/disable it during CAN OFF (**BUS\_CTRL\_1**; CAN[2:0] = 000).

**Figure 15** Clock and Data Recovery Block Diagram

#### 5.4.8.2 Setup of Clock and Data Recovery

It is strongly recommended to enable the clock and data recovery feature only when the setup of the clock and data recovery is finished.

The following sequence should be followed for enabling the clock and data recovery feature:

- Step 1: Switch CAN to OFF and **CDR\_EN** to OFF  
Write SPI Register **BUS\_CTRL\_1** (CAN[2:0] = 000).
- Step 2: Configure CDR Input clock frequency  
Write SPI Register **SWK\_CDR\_CTRL2** (SEL\_OSC\_CLK[1:0]).
- Step 3: Configure Bit timing Logic  
Write SPI Register **SWK\_BTL1\_CTRL** and adjust **SWK\_CDR\_LIMIT\_HIGH\_CTRL** and **SWK\_CDR\_LIMIT\_LOW\_CTRL** according to **Table 38**.
- Step 4: Enable Clock and Data Recovery  
Choose filter settings for Clock and Data recovery. Write SPI Register **SWK\_CDR\_CTRL1** with **CDR\_EN** = 1

Additional hints for the CDR configuration and operation:

- Even if the CDR is disabled, when the baud rate is changed, the settings of **SEL\_OSC\_CLK** in the register **SWK\_CDR\_CTRL1** and **SWK\_BTL1\_CTRL** have to be updated accordingly,
- The **SWK\_CDR\_LIMIT\_HIGH\_CTRL** and **SWK\_CDR\_LIMIT\_LOW\_CTRL** registers have to be also updated when the baud rate or clock frequency is changed (the CDR is discarding all the acquisitions and loses all acquired information, if the limits are reached - the **SWK\_BTL1\_CTRL** value is reloaded as starting point for the next acquisitions)
- When updating the CDR registers, it is recommended to disable the CDR and to enable it again only after the new settings are updated,
- The **SWK\_BTL2\_CTRL** register represents the sampling point position. It is recommended to be used at default value: 11 0011 (~80%)

## 5.4.9 Electrical Characteristics

**Table 15 Electrical Characteristics**

$V_S = 5.5 \text{ V to } 28 \text{ V}$ ;  $T_j = -40 \text{ }^\circ\text{C to } +150 \text{ }^\circ\text{C}$ ;  $4.75 \text{ V} < \text{VCAN} < 5.25 \text{ V}$ ;  $R_L = 60\Omega$ ; CAN Normal Mode; all voltages with respect to ground, positive current flowing into pin (unless otherwise specified)

| Parameter                                                                                              | Symbol                      | Values |      |      | Unit | Note or Test Condition                                                                                         | Number  |

1) Not subject to production test, tolerance defined by internal oscillator tolerance

2) Wake-up signaled via INT pin activation in SBC Stop Mode and via VCC1 ramping up with wake from SBC Sleep Mode.

3) WUP: time starts with end of last dominant phase of WUP; WUF: time starts with end of CRC delimiter of the WUF.

4) The minimum bit time corresponds to a maximum bit rate of 1 Mbit/s. The lower end of the bit rate depends on the protocol IC or the permanent dominant detection circuitry preventing a permanently dominant clamped bus.

5) Applies for an arbitration rate of up to 500kbps until the FDF bit is detected.

6) Not subject to production test; specified by design.

7) A data phase bit rate less or equal to four times of the arbitration bit rate or 2 Mbit/s, whichever is lower.

8) A data phase bit rate less or equal to ten times of the arbitration bit rate or 5 Mbit/s, whichever is lower.

## Voltage Regulator 1

## 6 Voltage Regulator 1

### 6.1 Block Description

**Figure 16** Module Block Diagram

#### Functional Features

- 5V low-drop voltage regulator
- Undervoltage monitoring with adjustable reset level, VCC1 prewarning and VCC1 short circuit detection ( $V_{RT1/2/3/4}$ ,  $V_{PW,f}$ ). Please refer to [Chapter 15.6](#) and [Chapter 15.7](#) for more information.
- Short circuit detection and switch off with undervoltage fail threshold, device enters SBC Fail-Safe Mode
- $\geq 470\text{nF}$  ceramic capacitor at voltage output for stability, with  $\text{ESR} < 1\Omega$  @  $f = 10\text{ kHz}$ , to achieve the voltage regulator control loop stability based on the safe phase margin (bode diagram).
- Output current capability up to  $I_{VCC1,lim}$ .

## Voltage Regulator 1

### 6.2 Functional Description

The Voltage Regulator 1 (=VCC1) is “ON” in SBC Normal and SBC Stop Mode and is disabled in SBC Sleep and in SBC Fail-Safe Mode. The regulator can provide an output current up to  $I_{VCC1,lim}$ .

For low-quiescent current reasons, the output voltage tolerance is decreased in SBC Stop Mode because only a low-power mode regulator with a lower accuracy ( $V_{CC1,out41}$ ) will be active for small loads. If the load current on VCC1 exceeds the selected threshold ( $I_{VCC1,peak1,r}$  or  $I_{VCC1,peak2,r}$ ) then the high-power mode regulator will be also activated to support an optimum dynamic load behavior. The current consumption will then increase by typ. 2.9mA.

If the load current on VCC1 falls below the selected threshold ( $I_{VCC1,peak1,f}$  or  $I_{VCC1,peak2,f}$ ), then the low-quiescent current mode is resumed again by disabling the high-power mode regulator.

Both regulators (low-power mode and high-power mode) are active in SBC Normal Mode.

Two different active peak thresholds can be selected via SPI:

- **I\_PEAK\_TH** = ‘0’ (default): the lower VCC1 active peak threshold 1 is selected with lowest quiescent current consumption in SBC Stop Mode (**I<sub>Stop\_1,25</sub>**, **I<sub>Stop\_1,85</sub>**);
- **I\_PEAK\_TH** = ‘1’: the higher VCC1 active peak threshold 2 is selected with an increased quiescent current consumption in SBC Stop Mode (**I<sub>Stop\_2,25</sub>**, **I<sub>Stop\_2,85</sub>**);

## Voltage Regulator 2

## 7 Voltage Regulator 2

## 7.1 Block Description

### Figure 19 Module Block Diagram

## Functional Features

- 5 V low-drop voltage regulator
- Protected against short to battery voltage, e.g. for off-board sensor supply
- Can also be used for CAN supply
- VCC2 undervoltage monitoring. Please refer to **Chapter 15.8** for more information
- Can be active in SBC Normal, SBC Stop, and SBC Sleep Mode (not SBC Fail-Safe Mode)
- VCC2 switch off after entering SBC Restart Mode. Switch off is latched, LDO must be enabled via SPI after shutdown.
- Overtemperature protection
- $\geq 470\text{nF}$  ceramic capacitor at output voltage for stability, with  $\text{ESR} < 1\Omega$  @  $f = 10\text{ kHz}$ , to achieve the voltage regulator control loop stability based on the safe phase margin (bode diagram).
- Output current capability up to  $I_{\text{VCC2,lim}}$ .

## Voltage Regulator 2

### 7.2 Functional Description

In SBC Normal Mode VCC2 can be switched on or off via SPI.

For SBC Stop- or Sleep Mode, the VCC2 has to be switched on or off before entering the respective SBC mode.

The regulator can provide an output current up to  $I_{VCC2,lim}$ .

For low-quiescent current reasons, the output voltage tolerance is decreased in SBC Stop Mode because only a low-power mode regulator with a lower accuracy ( $V_{CC2,out5}$ ) will be active for small loads. If the load current on VCC2 exceeds  $I_{VCC2} > I_{VCC2,lpeak,r}$  then the high-power mode regulator will also be enabled to support an optimum dynamic load behavior. The current consumption will then increase by typ. 2.9mA.

If the load current on VCC2 falls below the threshold ( $I_{VCC2} < I_{VCC2,lpeak,f}$ ), then the low-quiescent current mode is resumed again by disabling the high-power mode regulator.

Both regulators are active in SBC Normal Mode.

*Note: If the VCC2 output voltage is supplying external off-board loads, the application must consider the series resonance circuit built by cable inductance and decoupling capacitor at the load. Sufficient damping must be provided.*

#### 7.2.1 Short to Battery Protection

The output stage is protected for short to VBAT.

## External Voltage Regulator 3

## 8 External Voltage Regulator 3

### 8.1 Block Description

**Figure 22 Functional Block Diagram**

#### Functional Features

- Low-drop voltage regulator with external PNP transistor (up to 350mA with 470mΩ shunt resistor)
- Four high-voltage pins are used: VS, VCC3B, VCC3SH, VCC3REF
- Configurable as stand-alone regulator (5V or 3.3V output voltage selectable via SPI) or in load-sharing mode with VCC1 (5V output voltage)
- $\geq 4.7\mu\text{F}$  ceramic capacitor at output voltage for stability, with  $\text{ESR} < 150\text{m}\Omega$  @  $f = 10\text{ kHz}$  to achieve the voltage regulator control loop stability based on the safe phase margin (bode diagram).
- Overcurrent limitation with external shunt in stand-alone configuration
- Adjustable load current sharing ratio between VCC1 and VCC3 for load-sharing configuration
- Undervoltage shutdown in stand-alone configuration only

**Table 18** <sup>1)</sup>External Voltage Regulator Configurations depending on VCC1 output voltage

| VCC1 configuration | VCC3 voltage for <b>VCC3_V_CFG = 0</b> | VCC3 voltage for <b>VCC3_V_CFG = 1</b> |
|--------------------|----------------------------------------|----------------------------------------|
| VCC1 = 5.0V        | VCC3 = 5.0V                            | VCC3 = 3.3V                            |

1) This settings are valid only for the VCC3 stand-alone configuration. The bit **VCC3\_V\_CFG** is ignored for VCC3 load sharing configuration

## External Voltage Regulator 3

### 8.2 Functional Description

The external voltage regulator can be used as an independent voltage regulator or in load-sharing mode with VCC1. Setting **VCC3\_ON** in the **M\_S\_CTRL** register in SBC Normal Mode sets the stand-alone configuration of VCC3 as an independent voltage regulator. The load sharing configuration is set via the SPI bit **VCC3\_LS** in the **HW\_CTRL** register.

**Figure 23** Selecting the Configuration of the VCC3 Regulator

Depending on the configuration the regulator will act in the respective SBC Mode as described in [Table 19](#). After the VCC3 configuration has been selected, it cannot be changed anymore.

In stand-alone configuration the maximum current  $I_{CC3max}$  is defined by the current limitation determined by the used shunt. In load sharing configuration, the shunt is used to determine the current ratio between VCC1 and VCC3. Since the junction temperature of the external PNP transistor cannot be sensed by the SBC, it cannot be protected against overtemperature by the SBC. Therefore the thermal behavior has to be analyzed by the application.

For low-quiescent current reasons, the output voltage tolerance is decreased in SBC Stop Mode because a low-power mode regulator with a lower accuracy will be active for small loads. If the base current on VCC3 exceeds  $I_{VCC3base} > I_{VCC3base,peak,r}$  then the high-power mode regulator is enabled additionally to support an optimum dynamic load behavior. If the base current on VCC3 falls below the threshold ( $I_{VCC3base} < I_{VCC3base,peak,r}$ ), then the low-quiescent current consumption is resumed again by disabling the high-power mode regulator.

Only the high-power mode regulator is active in SBC Normal Mode.

The status of VCC3 is reported in the **SUP\_STAT\_2** SPI register. The regulator will switch OFF in case of VS dropping below **VS\_UV** regardless of the VCC3 configuration and will be automatically enabled again when exceeding this threshold voltage unless the control bit **VCC3\_VS\_UV\_OFF** is set, i.e. in order to keep VCC3 enabled below **VS\_UV** the bit **VCC3\_VS\_UV\_OFF** must be set. VCC3 will also stay active in SBC Stop Mode

## External Voltage Regulator 3

when the bit **VCC3\_LS\_STP\_ON** is set and when load sharing is configured (for detailed protection features see [Chapter 15.7](#) and [Chapter 16.3](#)).

**Table 19 External Voltage Regulator State by SBC Mode**

| SBC Mode       | Load Sharing Mode <sup>1)</sup> | Independent Voltage Regulator |
|----------------|---------------------------------|-------------------------------|
| INIT Mode      | OFF                             | OFF                           |
| Normal Mode    | Configurable                    | Configurable                  |
| Stop Mode      | OFF/Fixed <sup>2)</sup>         | Fixed                         |
| Sleep Mode     | OFF                             | Fixed                         |
| Restart Mode   | ON or ramping                   | Fixed                         |
| Fail-Safe Mode | OFF                             | OFF                           |

1) Behaves as VCC1 and has to be configured in SBC Normal Mode

2) Load Sharing operation in SBC Stop Mode is by default disabled for power saving reasons but **VCC3\_LS** bit will stay set. However, it can be also configured via the SPI bit **VCC3\_LS\_STP\_ON** to stay enabled in SBC Stop Mode.

*Note: The configuration of the VCC3 voltage regulator behavior must be done immediately after power-up of the device and cannot be changed afterwards as long as the device is supplied.*

*Note: As soon as the bit **VCC3\_ON** or **VCC3\_LS** is set for the first time, the configuration for VCC3 cannot be changed anymore. This configuration is valid - also after a SBC Soft Reset - as long as the SBC is powered.*

*Note: If the VCC3 output voltage is supplying external off-board loads, the application must consider the series resonance circuit built by cable inductance and decoupling capacitor at the load. Sufficient damping must be provided (e.g. a 100Ohm resistor between the PNP collector and VCC3REF with 10uF capacitor on collector - see also [Figure 24](#)).*

### 8.2.1 External Voltage Regulator as Independent Voltage Regulator

Configured as an independent voltage regulator the SBC offers with VCC3 a third supply which could be used as off-board supply e.g. for sensors due to the integrated HV pins VCC3B, VCC3SH, VCC3REF.

This configuration is set and locked by enabling **VCC3\_ON** while keeping **VCC3\_LS** = 0. VCC3 can be switched ON or OFF but the configuration cannot be changed anymore. However, the **SPI\_FAIL** is not set while trying to change the configuration.

An overcurrent limitation function is realized with the external shunt (see [Chapter 8.4](#) for calculating the desired shunt value) and the output current shunt voltage threshold ( $V_{shunt\_threshold}$ ). If this threshold is reached, then ICC3 is limited and only the current limitation bit **VCC3\_OC** is set (no other reaction) and can be cleared via SPI once the overcurrent condition is not present anymore. If the overcurrent limitation feature is not needed, then connect the pins VCC3SH and VS together.

In this configuration VCC3 has the undervoltage signalization enabled and an undervoltage event is signaled with the bit **VCC3\_UV** in the **SUP\_STAT\_2** SPI register.

*Note: To avoid undesired current consumption increase of the device it must be ensured that VCC3 is not connected to VCC1 in this configuration.*

## External Voltage Regulator 3

**Figure 24** Protecting the VCC3 against inductive short circuits when configured as an independent voltage regulator for off-board supply

### 8.2.2 External Voltage Regulator in Load Sharing Mode

The purpose of the load sharing mode is to increase the total current capability of VCC1 without increase of the power dissipation within the SBC. The load current is shared between the VCC1 internal regulator and the external PNP transistor of VCC3. **Figure 25** shows the setup for Load Sharing. Load Sharing is active in SBC Normal Mode. It can also be configured via SPI to stay active in SBC Stop Mode.

An input voltage up to  $V_{Sx,MAX}$  is regulated to  $V_{CC3,nom} = 5.0\text{ V}$  with a precision of  $\pm 2\%$  when used in the load sharing configuration in SBC Normal Mode.

This configuration is set and locked by enabling **VCC3\_LS** for the first time while **VCC3\_ON** has no function, i.e. keep **VCC3\_ON** = 0. Trying to change the VCC3 configuration after **VCC3\_LS** has been set will result in the **SPI\_FAIL** bit being set and keeping the VCC3 configurations unchanged. Load sharing will be automatically disabled (only if **VCC3\_LS\_STP\_ON** = 0) during SBC Stop Mode due to power saving reasons but the bit will remain set to automatically switch back on after returning to SBC Normal Mode. It must be ensured that the same VCC3 output voltage level is selected as for VCC1.

In this configuration VCC3 has no undervoltage signalization. VCC3 shuts down if Fail-Safe Mode is reached, e.g. due to undervoltage shutdown ( $V_{S,UV}$  monitoring).

VCC3 has no overcurrent limitation in this configuration and the shunt resistor is defining the load sharing ratio between the VCC1 and VCC3 load currents (see **Equation (8.2)** in **Chapter 8.4**). Thus, no overcurrent condition **VCC3\_OC** will be signaled in this configuration.

### External Voltage Regulator 3

### Figure 25 VCC3 in Load Sharing Configuration

### 8.3 External Components

Characterization is performed with the BCP52-16 from Infineon ( $I_{CC3} < 200$  mA) and with MJD253. Other PNP transistors can be used. However, the functionality must be checked in the application.

**Figure 25** shows one hardware set up used.

**Table 20 Bill of Materials for the  $V_{CC3}$  Function with and without load sharing configuration**

| Device | Vendor   | Reference / Value                 |
|--------|----------|-----------------------------------|
| C2     | Murata   | 10 $\mu$ F/10 V GCM31CR71A106K64L |
| RSHUNT | -        | 1 $\Omega$ (with / without LS)    |
| T1     | Infineon | BCP52-16                          |

*Note: The SBC is not able to ensure a thermal protection of the external PNP transistor. The power handling capabilities for the application must therefore be chosen according to the selected PNP device, the PCB layout and properties of the application to prevent thermal damage, e.g. via the shunt current limitation in stand alone configuration or by selecting the proper ICC1/ICC3 ratio in load-sharing configuration.*

**Note:** *To ensure an optimum EMC behavior of the VCC3 regulator when the VCC3 output is leaving the PCB, it is necessary to optimize the PCB layout to have the PNP very close to the SBC. If this is not sufficient or possible, an external capacitance should be placed to the off-board connector (see also [Chapter 17.1](#)).*

## External Voltage Regulator 3

### 8.4 Calculation of $R_{SHUNT}$

As a independent regulator, the maximum current  $I_{CC3max}$  where the limit starts and the bit  $I_{CC3} > I_{CC3max}$  is set is determined by the shunt resistor  $R_{SHUNT}$  and the Output Current Shunt Voltage Threshold  $V_{shunt\_threshold}$ .

The resistor can be calculated as following:

$$R_{SHUNT} = \frac{U_{shunt\_threshold}}{I_{CC3\ max}} \quad (8.1)$$

If VCC3 is configured for load sharing, then the shunt resistor determines the load sharing ratio between VCC1 and VCC3. The ratio can be calculated as following:

$$\frac{I_{CC\ 3}}{I_{CC\ 1}} = \frac{110\ \Omega / 105 - 15\ mV}{R_{SHUNT}} / I_{CC\ 1} \quad (a) \quad (8.2)$$

$$I_{CC\ 3} = \frac{I_{CC\ 1} \cdot 110\ \Omega / 105 - 15\ mV}{R_{SHUNT}} \quad (b)$$

Example: A shunt resistor with 470mΩ and a load current of 100mA out of VCC1 would result in  $I_{CC3} = 191mA$ .

### 8.5 Unused Pins

In case the VCC3 is not used in the application, it is recommended to connect the unused pins of VCC3 as followed:

- Connect VCC3SH to VS or leave open;
- Leave VCC3B open;
- Leave VCC3REF open
- Do not enable the VCC3 via SPI as this leads to increased current consumption

## External Voltage Regulator 3

### 8.6 Electrical Characteristics

$V_S = 5.5 \text{ V to } 28 \text{ V}$ ;  $T_j = -40^\circ\text{C to } +150^\circ\text{C}$ ; SBC Normal Mode; all outputs open; all voltages with respect to ground; positive current defined flowing into pin; unless otherwise specified.

**Table 21 Electrical Characteristics**

| Parameter                                                                                         | Symbol                 | Values |      |      | Unit          | Note or Test Condition                                                                                                                                  | Number   |

1) Threshold at which the current limitation starts to operate. This threshold is only active when VCC3 is configured for stand-alone configuration.

2) Tolerance includes load regulation and line regulation.

3)  $I_{VCC3\_peak}$  refers to the load current out of the collector of the external PNP device. This value can be calculated by multiplying the VCC3base active peak threshold ( $I_{VCC3base,peak}$ ) with the current gain of the PNP

## External Voltage Regulator 3

- 4) At  $T_j > 125^\circ\text{C}$ , the power transistor leakage could be increased, which has to be added to the quiescent current of the application independently if the regulator is turned on/off. To prevent an overvoltage condition at no load due to this increased leakage, an internal clamping structure will automatically turn on at typ. 200mV above the upper limit of the programmed output voltage.
- 5) Not subject to production test, specified by design.
- 6) a) Ratio will change depending on the chosen shunt resistor which value is correlating to the maximum power dissipation of the PNP pass device. See [Chapter 8.4](#) for the ratio calculation. The ratio will also change at low-drop operation.  
For supply voltages of  $5.5\text{V} < V_S < 6\text{V}$  the accuracy applies only for a total load current of 250mA.  
The load sharing ratio in SBC Stop Mode has +/-10% wider limits than specified.  
  
b) The output voltage precision in load sharing in SBC Stop Mode is according to  $V_{CC1} \pm 4\%$  or better for loads up to 20mA and +/-2% with loads greater than 20mA.  
In SBC Normal the +/-2% precision for 5V/3.3V tolerance is valid regardless of the applied load.

**Note:** *There is no thermal protection available for the external PNP transistor. Therefore, the application must be designed to avoid overheating of the PNP via the shunt current limitation in stand alone configuration and by selecting the proper  $ICC1/ICC3$  ratio in load-sharing configuration.*

**Note:** *In SBC Stop Mode, the same output voltage tolerance applies as in SBC Normal Mode when  $I_{VCC3}$  has exceeded the selected active peak threshold ( $I_{VCC3base, I_{peak}}$ ) but with increased current consumption.*

## High-Side Switch

# 9 High-Side Switch

## 9.1 Block Description

**Figure 29 High-Side Module Block Diagram**

### Features

- Dedicated supply pin VSHS for high-side outputs
- Overvoltage and undervoltage switch off - configurable via SPI
- Overcurrent detection and switch off
- Open load detection in ON-state
- PWM capability with internal timer configurable via SPI
- Switch recovery after removal of OV or UV condition configurable via SPI

## 9.2 Functional Description

The High-Side switches can be used for control of LEDs, as supply for the wake inputs and for other loads. The High-Side outputs can be controlled either directly via SPI by ([HS\\_CTRL1](#), [HS\\_CTRL2](#)), by the integrated timers or by the integrated PWM generators.

The high-side outputs are supplied by a dedicated supply pin VSHS (different to VS). The topology supports improved cranking condition behavior.

The configuration of the High-Side (Permanent On, PWM, cyclic sense, etc.) drivers must be done in SBC Normal Mode. The configuration is taken over in SBC Stop- or SBC Sleep Mode and cannot be modified. When entering SBC Restart Mode or SBC Fail-Safe Mode the HSx outputs are disabled.

## High-Side Switch

### 9.2.1 Over- and Undervoltage Switch Off

All HS drivers in on-state are switched off in case of overvoltage on VSHS ( $V_{SHS,OVD}$ ). If the voltage drops below the overvoltage threshold the HS drivers are activated again. The feature can be disabled by setting the SPI bit **HS\_OV\_SD\_EN**.

The HS drivers are switched off in case of undervoltage on VSHS ( $V_{SHS,UVD}$ ). If the voltage rises above the undervoltage threshold the HS drivers are activated again. The feature can be disabled by setting the SPI bit **HS\_UV\_SD\_EN**.

So after release of undervoltage or overvoltage condition the HS switch goes back to programmed state in which it was configured via SPI. This behavior is only valid if the bit **HS\_OV\_UV\_REC** is set to '1'. Otherwise the switches will stay off and the respective SPI control bits are cleared.

The overvoltage and undervoltage is signaled in the bits **VSHS\_OV** and **VSHS\_UV**, no other error bits are set.

### 9.2.2 Overcurrent Detection and Switch Off

If the load current exceeds the overcurrent shutdown threshold for a time longer then the overcurrent shutdown filter time the output is switched off.

The overcurrent condition and the switch off is signaled with the respective HSx\_OC\_OT bit in the register **HS\_OC\_OT\_STAT**. The HSx configuration is then reset to 000 by the SBC. To activate the High-Side again the HSx configuration has to be set to ON (001) or be programmed to a timer function. It is recommended to clear the overcurrent bit before activation the High-Side switch, as the bits are not cleared automatically by the SBC.

### 9.2.3 Open Load Detection

Open load detection on the High-Side outputs is done during on state of the output. If the current in the activated output falls below then Open Load Detection current, the open load is detected and signaled via the respective bit HS1\_OL, HS2\_OL, HS3\_OL, or HS4\_OL in the register **HS\_OL\_STAT**. The High-Side output stays activated. If the open load condition disappears the Open Load bit in the SPI can be cleared. The bits are not cleared automatically by the SBC.

### 9.2.4 HSx Operation in Different SBC Modes

- During SBC Stop and SBC Sleep Mode the HSx outputs can be used for the cyclic sense feature. The open-load detection, overcurrent shut down as well as overvoltage and undervoltage shutdown are available. The overcurrent shutdown protection feature may influence the wake-up behavior<sup>1)</sup>.
- the HSx output can also be enabled for SBC Stop and SBC Sleep Mode as well as controlled by the PWMx generator. The HSx outputs must be configured in SBC Normal Mode before entering a low-power mode.
- The HSx outputs are switched off during SBC Restart or SBC Fail-Safe Mode. They can be enabled via SPI if the failure condition is removed.

1) For the wake feature, the forced overcurrent shut down case must be considered in the user software for all SBC Modes, i.e. due to disabled HSx switches a level change might not be detected anymore at WKx pins.

## High-Side Switch

### 9.2.5 PWM and Timer Function

Two 8-bit PWM generators are dedicated to generate a PWM signal on the HS outputs, e.g. for brightness adjustment or compensation of supply voltage fluctuation. The PWM generators are mapped to the dedicated HS outputs, and the duty cycle can be independently configured with a 8bit resolution via SPI (**PWM1\_CTRL**, **PWM2\_CTRL**). Two different frequencies (200Hz, 400Hz) can be selected independently for every PWM generator in the register **PWM\_FREQ\_CTRL**.

#### **PWM Assignment and Configuration:**

- Configure duty cycle and frequency for respective PWM generator in **PWM1\_CTRL/PWM2\_CTRL** and **PWM\_FREQ\_CTRL**
- Assign PWM generator to respective HS switch(es) in **HSx\_CTRL**
- The PWM generation will start right after the HSx is assigned to the PWM generator (**HS\_CTRL1**, **HS\_CTRL2**)

#### **Assignment options of HS1... HS4**

- Timer 1
- Timer 2
- PWM 1
- PWM 2

#### **Minimum On-time during PWM Operation**

The min. on-time during PWM is limited by the actual on- and off-time of the respective HS switch, e.g. the PWM setting '0000 0001' could not be realized.

#### **Reliable Open-Load Detection during PWM Operation**

The minimum PWM setting for a reliable open-load detection is 3digits for a period of 400Hz and >2 digits for the frequency setting of 200Hz, i.e. the high-side on-time must be longer than  $t_{OL,HS}$ .

#### **Reliable Overcurrent Detection during PWM Operation**

The minimum PWM setting for a reliable overcurrent detection is >1 digit for a period of 400Hz and 1 digit for the frequency setting of 200Hz, i.e. the high-side on-time must be longer than  $t_{SD,HS}$ .

1) Not subject to production test, specified by design.

2) Not subject to production test, tolerance defined by internal oscillator tolerance.

3) Configure proper minimum PWM settings for reliable detection of overcurrent and open load measurement (see also [Chapter 9.2.5](#)).

## 10 High Speed CAN Transceiver

### 10.1 Block Description

**Figure 30 Functional Block Diagram**

### 10.2 Functional Description

The Controller Area Network (CAN) transceiver part of the SBC provides high-speed (HS) differential mode data transmission (up to 2 Mbaud) and reception in automotive and industrial applications. It works as an interface between the CAN protocol controller and the physical bus lines compatible to ISO 11898-2:2016 and SAE J2284.

The CAN transceiver offers low power modes to reduce current consumption. This supports networks with partially powered down nodes. To support software diagnostic functions, a CAN Receive-only Mode is implemented.

It is designed to provide excellent passive behavior when the transceiver is switched off (mixed networks, clamp15/30 applications).

A wake-up from the CAN wake capable mode is possible via a message on the bus. Thus, the microcontroller can be powered down or idled and will be woken up by the CAN bus activities.

The CAN transceiver is designed to withstand the severe conditions of automotive applications and to support 12 V applications.

High Speed CAN Transceiver

The different transceiver modes can be controlled via the SPI CAN bits.

Figure 31 shows the possible transceiver mode transitions when changing the SBC mode.

Figure 31 CAN Mode Control Diagram

CAN FD Support

CAN FD stands for ‘CAN with Flexible Data Rate’. It is based on the well established CAN protocol as specified in ISO 11898-1. CAN FD still uses the CAN bus arbitration method. The benefit is that the bit rate can be increased by switching to a shorter bit time at the end of the arbitration process and then to return to the longer bit time at the CRC delimiter, before the receivers transmit their acknowledge bits. See also Figure 32. In addition, the effective data rate is increased by allowing longer data fields. CAN FD allows the transmission of up to 64 data bytes compared to the 8 data bytes from the standard CAN.

Figure 32 Bite Rate Increase with CAN FD vs. Standard CAN

Not only the physical layer must support CAN FD but also the CAN controller. In case the CAN controller is not able to support CAN FD then the respective CAN node must at least tolerate CAN FD communication. This CAN FD tolerant mode is realized in the physical layer in combination with CAN Partial Networking. The TLE926x-

## High Speed CAN Transceiver

3QX variants of this family also support the CAN FD tolerant mode. See also [Chapter 5.4.7](#) for more detailed information on how to enable the CAN FD tolerant mode.

### 10.2.1 CAN OFF Mode

The CAN OFF Mode is the default mode after power-up of the SBC. It is available in all SBC Modes and is intended to completely stop CAN activities or when CAN communication is not needed. The CANH/L bus interface acts as a high impedance input with a very small leakage current. In CAN OFF Mode, a wake-up event on the bus will be ignored.

### 10.2.2 CAN Normal Mode

The CAN Transceiver is enabled via SPI in SBC Normal Mode. CAN Normal Mode is designed for normal data transmission/reception within the HS-CAN network. The Mode is available in SBC Normal Mode and in SBC Stop Mode. The bus biasing is set to  $V_{CAN}/2$ .

#### Transmission

The signal from the microcontroller is applied to the TXDCAN input of the SBC. The bus driver switches the CANH/L output stages to transfer this input signal to the CAN bus lines.

#### Enabling sequence

The CAN transceiver requires an enabling time  $t_{CAN,EN}$  before a message can be sent on the bus. This means that the TXDCAN signal can only be pulled LOW after the enabling time. If this is not ensured, then the TXDCAN needs to be set back to HIGH (=recessive) until the enabling time is completed.

Only the next dominant bit will be transmitted on the bus.

**Figure 33** shows different scenarios and explanations for CAN enabling.

**Figure 33** CAN Transceiver Enabling Sequence

#### Reduced Electromagnetic Emission

To reduce electromagnetic emissions (EME), the bus driver controls CANH/L slopes symmetrically.

#### Reception

Analog CAN bus signals are converted into digital signals at RXD via the differential input receiver.

---

**High Speed CAN Transceiver****10.2.3 CAN Receive Only Mode**

In CAN Receive Only Mode (RXD only), the driver stage is de-activated but reception is still operational. This mode is accessible by an SPI command in Normal Mode and in Stop Mode. The bus biasing is set to VCAN/2.

**10.2.4 CAN Wake Capable Mode**

This mode can be used in SBC Stop, Sleep, Restart and Normal Mode and it is used to monitor bus activities. It is automatically accessed in SBC Fail-Safe Mode. Both bus pins CANH/L are connected to GND via the input resistors.

A wake-up signal on the bus results in a change of behavior of the SBC, as described in [Table 23](#). The pins CANH/L are terminated to typ. 2.5V through the input resistors. As a wake-up signalization to the microcontroller, the RXD\_CAN pin is set LOW and will stay LOW until the CAN transceiver is changed to any other mode. After a wake-up event, the transceiver can be switched to CAN Normal Mode for communication via SPI.

As shown in [Figure 34](#), a wake-up pattern (WUP) is signaled on the bus by two consecutive dominant bus levels for at least  $t_{Wake1}$  (filter time  $t > t_{Wake1}$ ) and shorter than  $t_{Wake2}$ , each separated by a recessive bus level of greater than  $t_{Wake1}$  and shorter than  $t_{Wake2}$ .

## High Speed CAN Transceiver

**Figure 34 WUP detection following the definition in ISO 11898-2:2016**

### Rearming the Transceiver for Wake Capability

After a BUS wake-up event, the transceiver is woken. However, the **CAN** transceiver mode bits will still show wake capable (=‘01’) so that the RXD signal will be pulled low. There are two possibilities how the CAN transceiver’s wake capable mode is enabled again after a wake event:

- The CAN transceiver mode must be toggled, i.e. switched from Wake Capable Mode to CAN Normal Mode, CAN Receive Only Mode or CAN Off, before switching to CAN Wake Capable Mode again.
- Rearming is done automatically when the SBC is changed to SBC Stop, SBC Sleep, or SBC Fail-Safe Mode to ensure wake-up capability.

*Note: It is not necessary to clear the CAN wake-up bit **CAN\_WU** to become wake capable again. It is sufficient to toggle the CAN mode.*

*Note: The CAN module is supplied by an internal voltage when in CAN Wake Capable Mode, i.e. the module must not be supplied through the VCAN pin during this time. Before changing the CAN Mode to Normal Mode, the supply of VCAN has to be activated first.*

## High Speed CAN Transceiver

### Wake-Up in SBC Stop and Normal Mode

In SBC Stop Mode, if a wake-up is detected, it is always signaled by the INT output and in the **WK\_STAT\_1** SPI register. It is also signaled by RXDCAN pulled to low. The same applies for the SBC Normal Mode. The microcontroller should set the device from SBC Stop Mode to SBC Normal Mode, there is no automatic transition to Normal Mode.

For functional safety reasons, the watchdog will be automatically enabled in SBC Stop Mode after a Bus wake event in case it was disabled before (if bit **WD\_EN\_WK\_BUS** was configured to HIGH before).

### Wake-Up in SBC Sleep Mode

Wake-up is possible via a CAN message (filter time  $t > t_{Wake1}$ ). The wake-up automatically transfers the SBC into the SBC Restart Mode and from there to Normal Mode the corresponding RXD pin is set to LOW. The microcontroller is able to detect the low signal on RXD and to read the wake source out of the **WK\_STAT\_1** register via SPI. No interrupt is generated when coming out of Sleep Mode. The microcontroller can now for example switch the CAN transceiver into CAN Normal Mode via SPI to start communication.

**Table 23 Action due to CAN Bus Wake-Up**

| SBC Mode       | SBC Mode after Wake | VCC1       | INT  | RXD |
|----------------|---------------------|------------|------|-----|
| Normal Mode    | Normal Mode         | ON         | LOW  | LOW |
| Stop Mode      | Stop Mode           | ON         | LOW  | LOW |
| Sleep Mode     | Restart Mode        | Ramping Up | HIGH | LOW |
| Restart Mode   | Restart Mode        | ON         | HIGH | LOW |
| Fail-Safe Mode | Restart Mode        | Ramping up | HIGH | LOW |

---

**High Speed CAN Transceiver****10.2.5 TXD Time-out Feature**

If the TXD signal is dominant for a time  $t > t_{\text{TXD\_CAN\_TO}}$ , in CAN Normal Mode, the TXD time-out function deactivates the transmission of the signal at the bus. This is implemented to prevent the bus from being blocked permanently due to an error. The transmitter is disabled and the transceiver is switched to Receive Only Mode. The failure is stored in the SPI flag **CAN\_FAIL**. The CAN transmitter stage is activated again after the dominant time-out condition is removed and the transceiver is automatically switched back to CAN Normal Mode. The transceiver configuration stays unchanged.

**10.2.6 Bus Dominant Clamping**

If the HS CAN bus signal is dominant for a time  $t > t_{\text{BUS\_CAN\_TO}}$  in CAN Normal and Receive Only Mode a bus dominant clamping is detected and the SPI bit **CAN\_FAIL** is set. The transceiver configuration stays unchanged.

**10.2.7 Undervoltage Detection**

The voltage at the CAN supply pin is monitored only in CAN Normal and Receive Only Mode for SBC Normal and Stop Mode. In case of VCAN undervoltage a signalization via SPI bit **VCAN\_UV** is triggered and the SBC disables the transmitter stage. If the CAN supply reaches a higher level than the undervoltage detection threshold ( $\text{VCAN} > V_{\text{CAN\_UV}}$ ), the transceiver is automatically switched back to CAN Normal Mode. The transceiver configuration stays unchanged.

## High Speed CAN Transceiver

## High Speed CAN Transceiver

- 1) Not subject to production test, specified by design.
- 2)  $V_{SYM}$  shall be observed during dominant and recessive state and also during the transition dominant to recessive and vice versa while TXD is simulated by a square signal (50% duty cycle) with a frequency of up to 1 MHz (2 MBit/s);
- 3)  $R_{test}$  between supply (VS / VCAN) and 0V (GND);
- 4) Not subject to production test, tolerance defined by internal oscillator tolerance;
- 5) Wake-up is signaled via INT pin activation in SBC Stop Mode and via VCC1 ramping up with wake from SBC Sleep Mode;
- 6) Time starts with end of last dominant phase of WUP;

## 11 LIN Transceiver

### 11.1 Block Description

**Figure 37** Block Diagram

#### 11.1.1 LIN Specifications

The LIN network is standardized by international regulations. The device is compliant to the specification LIN 2.2. The physical layer specification LIN 2.2a is a super set of the previous LIN specifications, like LIN 2.0 or LIN 1.3. The integrated LIN transceivers are according to the LIN 2.2 standard.

The device is compliant to the physical layer standard SAE-J2602-2. The SAE-J2602-2 standard differs from the LIN 2.2 standard mainly by the lower data rate (10.4 kbit/s).

LIN Transceiver

11.2 Functional Description

The LIN Bus is a single wire, bi-directional bus, used for in-vehicle networks. The LIN transceivers implemented inside the TLE9263-3BQX are the interface between the micro controller and the physical LIN Bus. The digital output data from the micro controller are driven to the LIN bus via the TXD input pin on the TLE9263-3BQX. The transmit data stream on the TXD input is converted to a LIN bus signal with optimized slew rate to minimize the EME level of the LIN network. The RXD output sends back the information from the LIN bus to the micro controller. The receiver has an integrated filter network to suppress noise on the LIN Bus and to increase the EMI (Electro Magnetic Immunity) level of the transceiver.

Two logical states are possible on the LIN Bus according to the LIN Specification 2.2.

Every LIN network consists of a master node and one or more slave nodes. To configure the TLE9263-3BQX for master node applications, a resistor in the range of 1 kΩ and a reverse diode must be connected between the LIN bus and the power supply VSHS.

The different transceiver modes can be controlled via the SPI LIN1 and LIN2 bits.

Figure 38 shows the possible transceiver mode transitions when changing the SBC mode.

Figure 38 LIN Mode Control Diagram

11.2.1 LIN OFF Mode

The LIN OFF Mode is the default mode after power-up of the SBC. It is available in all SBC Modes and is intended to completely stop LIN activities or when LIN communication is not needed. In LIN OFF Mode, a wake-up event on the bus will be ignored.

## LIN Transceiver

### 11.2.2 LIN Normal Mode

The LIN Transceiver is enabled via SPI in SBC Normal Mode. LIN Normal Mode is designed for normal data transmission/reception within the LIN network. The Mode is available in SBC Normal Mode and in SBC Stop Mode.

#### Transmission

The signal from the microcontroller is applied to the TXDLIN input of the SBC. The bus driver switches the LIN output stage to transfer this input signal to the LIN bus line.

#### Enabling Sequence

The LIN transceiver requires an enabling time  $t_{LIN,EN}$  before a message can be sent on the bus. This means that the TXDLIN signal can only be pulled LOW after the enabling time. If this is not ensured, then the TXDLIN needs to be set back to high (=recessive) until the enabling time is completed.

Only the next dominant bit will be transmitted on the bus.

**Figure 39** shows different scenarios and explanations for LIN enabling.

**Figure 39** LIN Transceiver Enabling Sequence

#### Reduced Electromagnetic Emission

To reduce electromagnetic emissions (EME), the bus driver controls LIN slopes symmetrically. The configuration of the different slopes is described in [Chapter 11.2.8](#).

#### Reception

Analog LIN bus signals are converted into digital signals at RXD via the differential input receiver.

### 11.2.3 LIN Receive Only Mode

In LIN Receive Only Mode (RXD only), the driver stage is de-activated but reception is still possible. This mode is accessible by an SPI command and is available in SBC Normal and SBC Stop Mode.

## LIN Transceiver

### 11.2.4 LIN Wake Capable Mode

This mode can be used in SBC Stop, Sleep, Restart and Normal Mode by programming via SPI and it is used to monitor bus activities. It is automatically accessed in SBC Fail-Safe Mode. A wake up is detected, if a recessive to dominant transition on the LIN bus is followed by a dominant level of longer than  $t_{WK,BUS}$ , followed by a dominant to recessive transition. The dominant to recessive transition will cause a wake up of the LIN transceiver. A wake-up results in a different behavior of the SBC, as described in below [Table 25](#). As a signalization to the microcontroller, the RXD\_LIN pin is set LOW and will stay LOW until the LIN transceiver is changed to any other mode. After a wake-up event the transceiver can be switched to LIN Normal Mode for communication.

#### Rearming the transceiver for wake capability

After a BUS wake-up event, the transceiver is woken. However, the [LIN1](#) and [LIN2](#) transceiver mode bits will still show wake capable (=‘01’) so that the RXD signal will be pulled low. There are two possibilities how the LIN transceiver’s wake capable mode is enabled again after a wake event:

- The LIN transceiver mode must be toggled, i.e. switched to LIN Normal Mode, LIN Receive Only Mode or LIN Off, before switching to LIN Wake Capable Mode again.
- Rearming is done automatically when the SBC is changed to SBC Stop, SBC Sleep, or SBC Fail-Safe Mode to ensure wake-up capability.

#### Wake-Up in SBC Stop and SBC Normal Mode

In SBC Stop Mode, if a wake-up is detected, it is signaled by the INT output and in the [WK\\_STAT\\_1](#) SPI register. It is also signaled by RXDLIN put to LOW. The same applies for the SBC Normal Mode. The microcontroller should set the device to SBC Normal Mode, there is no automatic transition to Normal Mode.

For functional safety reasons, the watchdog will be automatically enabled in SBC Stop Mode after a Bus wake event in case it was disabled before (if bit [WD\\_EN\\_WK\\_BUS](#) was configured to HIGH before).

#### Wake-Up in SBC Sleep Mode

Wake-up is possible via a LIN message (filter time  $t > t_{WK,BUS}$ ). The wake-up automatically transfers the SBC into the SBC Restart Mode and from there to Normal Mode the corresponding RXD pin in set to LOW. The microcontroller is able to detect the low signal on RXD and to read the wake source out of the [WK\\_STAT\\_1](#) register via SPI. No interrupt is generated when coming out of Sleep Mode. The microcontroller can now switch the LIN transceiver into LIN Normal Mode via SPI to start communication.

**Table 25 Action due to a LIN BUS Wake-up**

| SBC Mode       | SBC Mode after Wake | VCC1       | INT  | RXD |
|----------------|---------------------|------------|------|-----|
| Normal Mode    | Normal Mode         | ON         | LOW  | LOW |
| Stop Mode      | Stop Mode           | ON         | LOW  | LOW |
| Sleep Mode     | Restart Mode        | Ramping Up | HIGH | LOW |
| Restart Mode   | Restart Mode        | ON         | HIGH | LOW |
| Fail-Safe Mode | Restart Mode        | Ramping up | HIGH | LOW |

## LIN Transceiver

### 11.2.5 TXD Time-out Feature

If the TXD signal is dominant for the time  $t > t_{\text{TXD\_LIN\_TO}}$ , the TXD time-out function deactivates the LIN transmitter output stage temporarily. The transceiver remains in recessive state. The TXD time-out functions prevents the LIN bus from being blocked by a permanent LOW signal on the TXD pin, caused by a failure. The failure is stored in the SPI flag **LIN1\_FAIL** and **LIN2\_FAIL**. The LIN transmitter stage is activated again after the dominant time-out condition is removed. The transceiver configuration stays unchanged.

**Figure 40 TXD Time-Out Function**

### 11.2.6 Bus Dominant Clamping

If the LIN bus signal is dominant for a time  $t > t_{\text{BUS\_LIN\_TO}}$  in LIN Normal and Receive Only Mode, then a bus dominant clamping is detected and the SPI bit **LIN1\_FAIL** and **LIN2\_FAIL** is set. The transceiver configuration stays unchanged.

### 11.2.7 Undervoltage Detection

In case the supply voltage is dropping below the VSHS undervoltage detection threshold ( $V_{\text{SHS}} < V_{\text{SHS\_UVD}}$ ), the TLE9263-3BQX disables the output and receiver stages. If the power supply reaches a higher level than the undervoltage detection threshold ( $V_{\text{SHS}} > V_{\text{SHS\_UVD}}$ ), the TLE9263-3BQX continues with normal operation. The transceiver configuration stays unchanged.

---

**LIN Transceiver****11.2.8 Slope Selection**

The LIN transceiver offers a LIN Low-Slope Mode for 10.4 kBaud communication and a LIN Normal-Slope Mode for 20 kBaud communication. The only difference is the behavior of the transmitter. In LIN Low-Slope Mode, the

transmitter uses a lower slew rate to further reduce the EME compared to Normal-Slope Mode. This complies with SAE J2602 requirements. By default, the device works in LIN Normal-Slope Mode. The selection of LIN Low-Slope Mode is done by an SPI bit **LIN\_LSM** and will become effective as soon as CSN goes 'HIGH'. Only the LIN Slope is changed. The selection is accessible in SBC Normal Mode only.

**11.2.9 Flash Programming via LIN**

The device allows LIN flash programming, e.g. of another LIN Slave with a communication of up to 115 kBaud. This feature is enabled by de-activating the slope control mechanism via a SPI command (bit LIN\_FLASH) and will become effective as soon as CSN goes 'HIGH'. The SPI bit can be set in SBC Normal Mode.

*Note: It is recommended to perform flash programming only at nominal supply voltage  $V_{SHS} = 13.5V$  to ensure stable data communication.*

## LIN Transceiver

## 11.3 Electrical Characteristics

Table 26 Electrical Characteristics

$V_{SHS} = 5.5 \text{ V to } 18 \text{ V}$ ,  $T_j = -40 \text{ }^{\circ}\text{C to } +150 \text{ }^{\circ}\text{C}$ ,  $R_L = 500 \text{ } \Omega$ , all voltages with respect to ground, positive current flowing into pin (unless otherwise specified)

## LIN Transceiver

**Figure 42** Timing Diagram for Dynamic Characteristics

## Wake and Voltage Monitoring Inputs

# 12 Wake and Voltage Monitoring Inputs

## 12.1 Block Description

**Figure 43 Wake Input Block Diagram**

### Features

- Three High-Voltage inputs with a 3V (typ.) threshold voltage
- Alternate Measurement function for high-voltage sensing via WK1 and WK2
- Wake-up capability for power saving modes
- Edge sensitive wake feature LOW to HIGH and HIGH to LOW
- Pull-up and Pull-down current sources, configurable via SPI
- Selectable configuration for static sense or cyclic sense working with TIMER1, TIMER2
- In SBC Normal and SBC Stop Mode the level of the WK pin can be read via SPI even if the respective WK is not enabled as a wake source.

## Wake and Voltage Monitoring Inputs

### 12.2 Functional Description

The wake input pins are edge-sensitive inputs with a switching threshold of typically 3V. This means that both transitions, HIGH to LOW and LOW to HIGH, result in a signalization by the SBC. The signalization occurs either in triggering the interrupt in SBC Normal Mode and SBC Stop Mode or by a wake up of the device in SBC Sleep and SBC Fail-Safe Mode.

Two different wake detection modes can be selected via SPI:

- Static sense: WK inputs are always active
- Cyclic sense: WK inputs are only active for a certain time period (see [Chapter 5.2.1](#))

Two different filter times of 16μs or 64μs can be selected to avoid a parasitic wake-up due to transients or EMC disturbances in static sense configuration.

The filter time ( $t_{FWK1}$ ,  $t_{FWK2}$ ) is triggered by a level change crossing the switching threshold and a wake signal is recognized if the input level will not cross again the threshold during the selected filter time.

**Figure 44** shows a typical wake-up timing and parasitic filter.

**Figure 44** Wake-up Filter Timing for Static Sense

The wake-up capability for each WK pin can be enabled or disabled via SPI command in the [WK\\_CTRL\\_2](#) register.

The wake source for a wake via a WKx pin can always be read in the register [WK\\_STAT\\_1](#) at the bits WK1\_WU, WK2\_WU, and WK3\_WU.

The actual voltage level of the WK pin (LOW or HIGH) can always be read in SBC Normal and SBC Stop Mode in the register [WK\\_LVL\\_STAT](#). During Cyclic Sense, the register shows the sampled levels of the respective WK pin.

If FO2...3 are configured as WK inputs in its alternative function (16μs static filter time), then the wake events will be signalled in the register [WK\\_STAT\\_2](#).

## Wake and Voltage Monitoring Inputs

### 12.2.1 Wake Input Configuration

To ensure a defined and stable voltage levels at the internal comparator input it is possible to configure integrated current sources via the SPI register **WK\_PUPD\_CTRL**. In addition, the wake detection modes (including the filter time) can be configured via the SPI register **WK\_FLT\_CTRL**. An example illustration for the automatic switching configuration is shown in **Figure 45**.

**Table 27 Pull-Up / Pull-Down Resistor**

| WKx_PUPD_1 | WKx_PUPD_0 | Current Sources     | Note                                                                                                                               |
|------------|------------|---------------------|------------------------------------------------------------------------------------------------------------------------------------|
| 0          | 0          | no current source   | WKx input is floating if left open (default setting)                                                                               |
| 0          | 1          | pull-down           | WKx input internally pulled to GND                                                                                                 |
| 1          | 0          | pull-up             | WKx input internally pulled to internal 5V supply                                                                                  |
| 1          | 1          | Automatic switching | If a high level is detected at the WKx input the pull-up source is activated, if low level is detected the pull down is activated. |

**Note:** If there is no pull-up or pull-down configured on the WK input, then the respective input should be tied to GND or VS on board to avoid unintended floating of the pin and subsequent wake events.

**Figure 45 Illustration for Pull-Up / Down Current Sources with Automatic Switching Configuration**

**Table 28 Wake Detection Configuration and Filter Time**

| WKx_FLT_1 | WKx_FLT_0 | Filter Time | Description                                                                                          |
|-----------|-----------|-------------|------------------------------------------------------------------------------------------------------|
| 0         | 0         | Config A    | static sense, 16μs filter time                                                                       |
| 0         | 1         | Config B    | static sense, 64μs filter time                                                                       |
| 1         | 0         | Config C    | Cyclic sense, Timer 1, 16μs filter time. Period, On-time configurable in register <b>TIMER1_CTRL</b> |
| 1         | 1         | Config D    | Cyclic sense, Timer 2, 16μs filter time. Period, On-time configurable in register <b>TIMER2_CTRL</b> |

Config A and B are intended for static sense with two different filter times.

---

### Wake and Voltage Monitoring Inputs

Config C or D are intended for cyclic sense configuration. With the filter settings, the respective timer needs to be assigned to one or more HS output, which supplies an external circuit connected to the WKx pin, e.g. HS1 controlled by Timer 2 (HS1 = 010) and connected to WK3 via an switch circuitry - see also [Chapter 5.2](#).

## Wake and Voltage Monitoring Inputs

### 12.2.2 Alternate Measurement Function with WK1 and WK2

#### 12.2.2.1 Block Description

This function provides the possibility to measure a voltage, e.g. the unbuffered battery voltage, with the protected WK1 HV-input. The measured voltage is routed out at WK2. It allows for example a voltage compensation for LED lighting by changing the duty cycle of the High-Side outputs. A simple voltage divider needs to be placed externally to provide the correct voltage level to the microcontroller A/D converter input.

The function is available in SBC Normal Mode and it is disabled in all other modes to allow a low-quiescent current operation. The measurement function can be used instead of the WK1 and WK2 wake and level signalling capability.

The benefits of the function is that the signal is measured by a HV-input pin and that there is no current flowing through the resistor divider during low-power modes.

The functionality is shown in a simplified application diagram in [Figure 65](#).

#### 12.2.2.2 Functional Description

This measurement function is by default disabled. In this case, WK1 and WK2 have the regular wake and voltage level signalization functionality. The switch S1 is open for this configuration (see [Figure 65](#)).

The measurement function can be enabled via the SPI bit [WK\\_MEAS](#).

If [WK\\_MEAS](#) is set to '1', then the measurement function is enabled and switch S1 is closed in SBC Normal Mode. S1 is open in all other SBC modes. If this function the pull-up and down currents of WK1 and WK2 are disabled, and the internal WK1 and WK2 signals are gated. In addition, the settings for WK1 and WK2 in the registers [WK\\_PUPD\\_CTRL](#), [WK\\_FLT\\_CTRL](#) and [WK\\_CTRL\\_2](#) are ignored but changing these setting is not prevented. The registers [WK\\_STAT\\_1](#) and [WK\\_LVL\\_STAT](#) are not updated with respect to the inputs WK1 and WK2.

However, if only WK1 or WK2 are set as wake sources and a SBC Sleep Mode command is set, then the [SPI\\_FAIL](#) flag will be set and the SBC will be changed into SBC Restart Mode (see [Chapter 5.1](#) also for wake capability of WK1 and WK2).

**Table 29 Differences between Normal WK Function and Measurement Function**

| Affected Settings/Modules for WK1 and WK2 Inputs | <a href="#">WK_MEAS</a> = 0                                                                                              | <a href="#">WK_MEAS</a> = 1                                                                                                                                                                                                                                |

2) Not subject to production test, tolerance defined by internal oscillator tolerance

Wake and Voltage Monitoring Inputs

Figure 46 Typical Drop Voltage Characteristics of S1 (between WK1 & WK2)

## Interrupt Function

# 13 Interrupt Function

## 13.1 Block and Functional Description

**Figure 47** Interrupt Block Diagram

The interrupt is used to signalize special events in real time to the microcontroller. The interrupt block is designed as a push/pull output stage as shown in **Figure 47**. An interrupt is triggered and the INT pin is pulled low (active low) for  $t_{INT}$  in SBC Normal and Stop Mode and it is released again once  $t_{INT}$  is expired. The minimum HIGH-time of INT between two consecutive interrupts is  $t_{INTD}$ . An interrupt does not cause a SBC mode change. Two different interrupt classes could be selected via the SPI bit **INT\_GLOBAL**:

- Class 1 (wake interrupt - **INT\_GLOBAL**=0): all wake-up events stored in the wake status SPI register (**WK\_STAT\_1** and **WK\_STAT\_2**) cause an interrupt (default setting). An interrupt is only triggered if the respective function is also enabled as a wake source (including GPIOx if configured as a wake input). The CAN time out signalization **CANTO** is also considered as a wake source. Therefore, the interrupt mask bit **CANTO\_MASK** has higher priority than the bit **INT\_GLOBAL**, i.e. Integral is not taken into account for CANTO.
- Class 2 (global interrupt - **INT\_GLOBAL**=1): in addition to the wake-up events, all signalled failures stored in the other status registers cause an interrupt (the register **WK\_LVL\_STAT** is not generating interrupts)

*Note: The errors which will cause SBC Restart or SBC Fail-Safe Mode ( $V_{cc1\_UV}$ ,  $WD\_FAIL$ ,  $V_{CC1\_SC}$ ,  $TSD2$ ,  $FAILURE$ ) are the exceptions of an INT generation on status bits. Also POR and  $DEV\_STAT\_x$  and will not generate interrupts.*

In addition to this behavior, an INT will be triggered when the SBC is sent to SBC Stop Mode and not all bits were cleared in the **WK\_STAT\_1** and **WK\_STAT\_2** register.

The SPI status registers are updated at every falling edge of the INT pulse. All interrupt events are stored in the respective register (except the register **WK\_LVL\_STAT**) until the register is read and cleared via SPI command. A second SPI read after reading out the respective status register is optional but recommended to verify that the interrupt event is not present anymore. The interrupt behavior is shown in **Figure 48** for class 1 interrupts. The behavior for class 2 is identical.

The INT pin is also used during SBC Init Mode to select the hardware configuration of the device. See **Chapter 5.1.1** for further information.

Interrupt Function

1) Output Voltage Value also determines device configuration during SBC Init Mode

2) Not subject to production test, tolerance defined by internal oscillator tolerance.

## Fail Outputs

# 14 Fail Outputs

## 14.1 Block and Functional Description

**Figure 49** Simplified Fail Output Block Diagram for FO1/2 and for FO3/TEST

The fail outputs consist of a failure logic block and three open-drain outputs (FO1, FO2, FO3) with active-low signalization.

The fail outputs are activated due to following failure conditions:

- Watchdog trigger failure (For config 3&4 only after the 2nd watchdog trigger failure and for config 1&2 after 1st watchdog trigger failure)
- Thermal shutdown TSD2
- VCC1 short to GND
- VCC1 overvoltage (only if the SPI bit **VCC1\_OV\_RST** is set)
- After 4 consecutive VCC1 undervoltage event (see [Chapter 15.6](#) for details)

At the same time SBC Fail-Safe Mode is entered (exceptions are watchdog trigger failures depending on selected configurations - see [Chapter 5.1.1](#)).

The fail output activation is signalled in the SPI bit **FAILURE** of the register **DEV\_STAT**.

For testing purposes only the Fail Outputs can also be activated via SPI by setting the bit **FO\_ON**. This bit is independent of the FO failure bits. In case that there is no failure condition, the FO outputs can also be turned off again via SPI, i.e. no successful watchdog trigger is needed.

The entry of SBC Fail-Safe Mode due to a watchdog failure can be configured as described in [Chapter 5.1.1](#).

In order to deactivate the fail outputs in SBC Normal Mode the failure conditions must not be present anymore (e.g. TSD2, VCC1 short circuit, etc) and the bit **FAILURE** needs to be cleared via SPI command.

In case of a watchdog failure the correct procedure to deactivate the fail outputs is:

- a successful WD trigger, i.e. **WD\_FAIL** must be cleared
- clearing of the **FAILURE** bit

**WD\_FAIL** will also be cleared when going to SBC Sleep or SBC Fail-Safe Mode due to another failure (not a WD failure) or if the watchdog is disabled in SBC Stop Mode

## Fail Outputs

**Note:** The Fail output pin is triggered for any of the above described failures. No FAILURE is caused for the 1st watchdog failure if selected for Config2.

The three fail outputs are activated simultaneously with following output functionalities:

- FO1: Static fail output
- FO2: 1.25Hz, 50% (typ.) duty cycle, e.g. to generate an indicator signal
- FO3: 100Hz PWM, 20% (typ.) duty cycle, e.g. to generate a dimmed rear light from a break light.

**Note:** The duty cycle for FO3 can be configured via SPI option to 20%, 10%, 5% or 2.5%. Default value is 20%. See the register **FO\_DC** for configuration.

### 14.1.1 General Purpose I/O Functionality of FO2 and FO3 as Alternate Function

In case that FO2 and FO3 are not used in the application, those pins can also be configured with an alternate function as high-voltage (VSHS related) General Purpose I/O pins.

**Figure 50** Simplified General Purpose I/O block diagram for FO2 and FO3/TEST

The pins are by default configured as FO pins. The configuration is done via the SPI register **GPIO\_CTRL**. The alternate function can be:

- Wake Inputs: The detection threshold  $V_{GPIO,th}$  is similar as for the WK inputs. The wake-up detection behavior is the same as for WKx pins. Wake events are stored and reported in **WK\_STAT\_2**.
- Low-Side Switches: The switch is able to drive currents of up to 10mA (see also  $V_{GPIO,L1}$ ). It is self-protected with regards to current limitation. No other diagnosis is implemented.
- High-Side Switches: The switch is able to drive currents up to 10mA (see also  $V_{GPIO,H1}$ ). It is self-protected with regards to current limitation. No other diagnosis is implemented.
- If configured as GPIO then the respective level at the pin will be shown in **WK\_LVL\_STAT** in SBC Normal and Stop Mode. This is also the case if configured as LS/HS and can serve as a feedback about the respective state. GPIO2 is shared with the TEST level bit.

**Table 32** describes the behavior of the FO/GPIO pins in their different configurations and SBC modes.

## Fail Outputs

**Table 32 Fail-Output and GPIO configuration behavior during the respective SBC Modes**

| FOx Configuration | SBC Normal Mode | SBC Stop Mode | SBC Sleep Mode | SBC Restart Mode | SBC Fail-Safe Mode |
|-------------------|-----------------|---------------|----------------|------------------|--------------------|
| FOx (default)     | configurable    | fixed         | fixed          | active / fixed   | active             |
| OFF               |                 | OFF           | OFF            | OFF              | OFF                |
| Wake Input        |                 | wake capable  | wake capable   | wake capable     | OFF                |
| Low-Side          |                 | fixed         | fixed          | OFF              | OFF                |
| High-Side         |                 | fixed         | fixed          | OFF              | OFF                |

### Explanation of FO/GPIO states:

- configurable: settings can be changed in this SBC mode
- fixed: settings stay as configured in SBC Normal Mode
- active: FOx is activated due to a failure leading to SBC Restart or Fail-Safe Mode.

### Restart Behavior:

The behavior during SBC Restart and Fail-Safe Mode as well as the transition to SBC Normal Mode is as follows:

- if configured as Wake Input: it will stay wake capable during SBC Restart Mode and OFF while in SBC Fail-Safe Mode. It will resume wake capability when leaving SBC Restart Mode (SPI register is not modified)
- if configured as Low-Side or High-Side: They will be disabled during SBC Restart and Fail-Safe Mode. After leaving SBC Restart Mode the previously configured function will be resumed (SPI register is not modified)
- if configured as FO and activated due to a failure: FO will stay activated during SBC Restart Mode and when entering SBC Normal Mode (SPI register is not modified)

*Note: In order to avoid unintentional entry of SBC Development Mode care must be taken that the level of FO3/TEST is HIGH during device power up and SBC Init Mode.*

*Note: The FOx drivers are supplied via VS. However, the GPIO HS switches (FO2, FO3/TEST) are supplied by VSHS*

## Fail Outputs

## 14.2 Electrical Characteristics

**Table 33 Electrical Characteristics**

$V_{SHS} = 5.5\text{ V to }28\text{ V}$ ;  $T_j = -40\text{ °C to }+150\text{ °C}$ ; SBC Normal Mode; all voltages with respect to ground; positive current defined flowing into pin; unless otherwise specified.<sup>1)</sup>

---

## Fail Outputs

- 1) The FOx drivers are supplied via VS. However, the GPIO HS switches (FO2, FO3/TEST) are supplied by VSHS
- 2) The external capacitance on this pin must be limited to less than 10nF to ensure proper detection of SBC Development Mode and SBC User Mode operation.
- 3) Not subject to production test, tolerance defined by internal oscillator tolerance.
- 4) The duty cyclic is adjustable via the SPI bits **FO\_DC**.
- 5) Not subject to production test, specified by design.
- 6) Applies also for TEST voltage input level

## Supervision Functions

## 15 Supervision Functions

### 15.1 Reset Function

**Figure 51** Reset Block Diagram

#### 15.1.1 Reset Output Description

The reset output pin RO provides a reset information to the microcontroller, for example, in the event that the output voltage has fallen below the undervoltage threshold  $V_{RT1/2/3/4}$ . In case of a reset event, the reset output RO is pulled to low after the filter time  $t_{RF}$  and stays low as long as the reset event is present plus a reset delay time  $t_{RD1}$ . When connecting the SBC to battery voltage, the reset signal remains LOW initially. When the output voltage  $V_{CC1}$  has reached the reset default threshold  $V_{RT1,r}$ , the reset output RO is released to HIGH after the reset delay time  $t_{RD1}$ . A reset can also occur due to a watchdog trigger failure. The reset threshold can be adjusted via SPI, the default reset threshold is  $V_{RT1,f}$ . The RO pin has an integrated pull-up resistor. In case reset is triggered, it will be pulled low for  $V_{CC1} \geq 1V$  and for  $VS \geq V_{POR,f}$  (see also [Chapter 15.3](#)).

The timings for the RO triggering regarding VCC1 undervoltage and watchdog trigger is shown in [Figure 52](#).

## Supervision Functions

Figure 52 Reset Timing Diagram

## 15.1.2 Soft Reset Description

In SBC Normal and SBC Stop Mode, it is also possible to trigger a device internal reset via a SPI command in order to bring the SBC into a defined state in case of failures. In this case the microcontroller must send a SPI command and set the **MODE** bits to '11' in the **M\_S\_CTRL** register. As soon as this command becomes valid, the SBC is set back to SBC INIT Mode and all SPI registers are set to their default values (see SPI [Chapter 16.5](#) and [Chapter 16.6](#)).

Two different soft reset configurations are possible via the SPI bit **SOFT\_RESET\_RO**:

- The reset output (RO) is triggered when the soft reset is executed (default setting, the same reset delay time **t<sub>RD1</sub>** applies)
- The reset output (RO) is not triggered when the soft reset is executed

*Note: The device must be in SBC Normal Mode or SBC Stop Mode when sending this command. Otherwise, the command will be ignored.*

## Supervision Functions

### 15.2 Watchdog Function

The watchdog is used to monitor the software execution of the microcontroller and to trigger a reset if the microcontroller stops serving the watchdog due to a lock up in the software.

Two different types of watchdog functions are implemented and can be selected via the bit **WD\_WIN**:

- Time-Out Watchdog (default value)
- Window Watchdog

The respective watchdog functions can be selected and programmed in SBC Normal Mode. The configuration stays unchanged in SBC Stop Mode.

Please refer to **Table 34** to match the SBC Modes with the respective watchdog modes.

**Table 34 Watchdog Functionality by SBC Modes**

| SBC Mode     | Watchdog Mode                | Remarks                                                              |
|--------------|------------------------------|----------------------------------------------------------------------|
| INIT Mode    | Starts with Long Open Window | Watchdog starts with Long Open Window after RO is released           |
| Normal Mode  | WD Programmable              | Window Watchdog, Time-Out watchdog or switched OFF for SBC Stop Mode |
| Stop Mode    | Watchdog is fixed or OFF     |                                                                      |
| Sleep Mode   | OFF                          | SBC will start with Long Open Window when entering SBC Normal Mode.  |
| Restart Mode | OFF                          | SBC will start with Long Open Window when entering SBC Normal Mode.  |

The watchdog timing is programmed via SPI command. As soon as the watchdog is programmed, the timer starts with the new setting and the watchdog must be served. The watchdog is triggered by sending a valid SPI-write command to the watchdog configuration register. The trigger SPI command is executed when the Chip Select input (CSN) becomes HIGH.

When coming from SBC Init, SBC Restart Mode or in certain cases from SBC Stop Mode, the watchdog timer is always started with a long open window. The long open window ( $t_{LW} = 200\text{ms}$ ) allows the microcontroller to run its initialization sequences and then to trigger the watchdog via SPI.

The watchdog timer period can be selected via the watchdog timing bit field (**WD\_TIMER**) and is in the range of 10 ms to 1000 ms. This setting is valid for both watchdog types.

The following watchdog timer periods are available:

- WD Setting 1: 10ms
- WD Setting 2: 20ms
- WD Setting 3: 50ms
- WD Setting 4: 100ms
- WD Setting 5: 200ms
- WD Setting 6: 500ms
- WD Setting 7: 1000ms

In case of a watchdog reset, SBC Restart or SBC Fail-Safe Mode is entered according to the configuration and the SPI bits **WD\_FAIL** are set. Once the RO goes HIGH again the watchdog immediately starts with a long open window the SBC enters automatically SBC Normal Mode.

In SBC Development Mode the watchdog is OFF and therefore no reset and interrupt are generated due to a watchdog failure.

## Supervision Functions

Depending on the configuration, the **WD\_FAIL** bits will be set after a watchdog trigger failure as follows:

- In case an incorrect WD trigger is received (triggering in the closed watchdog window or when the watchdog counter expires without a valid trigger) then the **WD\_FAIL** bits will be increased (showing the number of incorrect WD triggers)
- For config 2: the bits can have the maximum value of '01'
- For config 1, 3 and 4: the bits can have the maximum value of '10'

The **WD\_FAIL** bits are cleared automatically when following conditions apply:

- After a successful watchdog trigger
- When the watchdog is OFF: in SBC Stop Mode after successfully disabling it, in SBC Sleep Mode, or in SBC Fail-Safe Mode (except for a watchdog failure)

### 15.2.1 Time-Out Watchdog

The time-out watchdog is an easier and less secure watchdog than a window watchdog as the watchdog trigger can be done at any time within the configured watchdog timer period.

A correct watchdog service immediately results in starting a new watchdog timer period. Taking the tolerances of the internal oscillator into account leads to the safe trigger area as defined in **Figure 53**.

If the time-out watchdog period elapses, a watchdog reset is created by setting the reset output RO low and the SBC switches to SBC Restart or SBC Fail-Safe Mode.

**Figure 53 Time-out Watchdog Definition**

## Supervision Functions

### 15.2.2 Window Watchdog

Compared to the time-out watchdog the characteristic of the window watchdog is that the watchdog timer period is divided between an closed and an open window. The watchdog must be triggered within the open window.

A correct watchdog trigger results in starting the window watchdog period by a closed window followed by an open window.

The watchdog timer period is at the same time the typical trigger time and defines the middle of the open window. Taking the oscillator tolerances into account leads to a safe trigger area of:

$$t_{WD} \times 0.72 < \text{safe trigger area} < t_{WD} \times 1.20.$$

The typical closed window is defined to a width of 60% of the selected window watchdog timer period. Taking the tolerances of the internal oscillator into account leads to the timings as defined in **Figure 54**.

A correct watchdog service immediately results in starting the next closed window.

Should the trigger signal meet the closed window or should the watchdog timer period elapse, then a watchdog reset is created by setting the reset output RO low and the SBC switches to SBC Restart or SBC Fail-Safe Mode.

**Figure 54 Window Watchdog Definition**

---

**Supervision Functions****15.2.3 Watchdog Setting Check Sum**

A check sum bit is part of the SPI command to trigger the watchdog and to set the watchdog setting.

The sum of the 8 data bits in the register WWD\_CTRL needs to have even parity (see [Equation \(15.1\)](#)). This is realized by either setting the bit **CHECKSUM** to 0 or 1. If the check sum is wrong, then the SPI command is ignored, i.e. the watchdog is not triggered or the settings are not changed and the bit SPI\_FAIL is set.

The checksum is calculated by taking all 8 data bits into account. The written value of the reserved bit 3 of the WWD\_CTRL register is considered (even if read as '0' in the SPI output) for checksum calculation, i.e. if a 1 is written on the reserved bit position, then a 1 will be used in the checksum calculation.

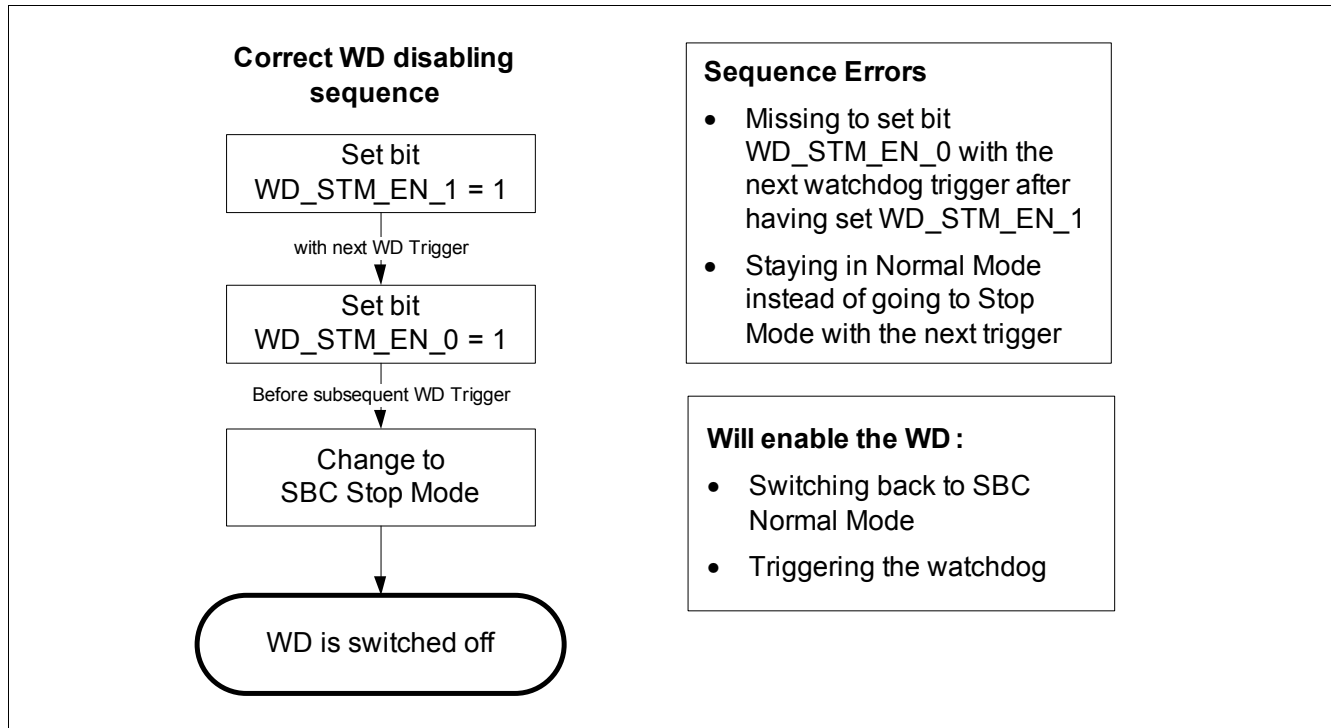

(15.1)

$$\text{CHKSUM} = \text{Bit15} \oplus \dots \oplus \text{Bit8}$$

## Supervision Functions

## 15.2.4 Watchdog during SBC Stop Mode

The watchdog can be disabled for SBC Stop Mode in SBC Normal Mode. For safety reasons, there is a special sequence to be followed in order to disable the watchdog as described in [Figure 55](#). Two different SPI bits (**WD\_STM\_EN\_0**, **WD\_STM\_EN\_1**) in the registers **WK\_CTRL\_1** and **WD\_CTRL** need to be set.

**Figure 55** Watchdog disabling sequence in SBC Stop Mode

If a sequence error occurs, then the bit **WD\_STM\_EN\_1** will be cleared and the sequence has to be started again.

The watchdog can be enabled by triggering the watchdog in SBC Stop Mode or by switching back to SBC Normal Mode via SPI command. In both cases the watchdog will start with a long open window and the bits **WD\_STM\_EN\_1** and **WD\_STM\_EN\_0** are cleared. After the long open window the watchdog has to be served as configured in the **WD\_CTRL** register.

*Note:* The bit **WD\_STM\_EN\_0** will be cleared automatically when the sequence is started and it was 1 before.

---

**Supervision Functions****15.2.5 Watchdog Start in SBC Stop Mode due to Bus Wake**

In SBC Stop Mode the Watchdog can be disabled. In addition a feature is available which will start the watchdog with any BUS wake (CAN or LIN) during SBC Stop Mode. The feature is enabled by setting the bit **WD\_EN\_WK\_BUS** = 1

(= default value after POR). The bit can only be changed in SBC Normal Mode and needs to be programmed before starting the watchdog disable sequence.

A wake on CAN and LINx will generate an interrupt and the RXD pin for LINx or CAN is pulled to low. By these signals the microcontroller is informed that the watchdog is started with a long open window. After the long open window the watchdog has to be served as configured in the **WD\_CTRL** register.

To disable the watchdog again, the SBC needs to be switched to Normal Mode and the sequence needs to be sent again.

## Supervision Functions

## 15.3 VS Power On Reset

At power up of the device, the VS Power on Reset is detected when  $V_S > V_{POR,r}$  and the SPI bit **POR** is set to indicate that all SPI registers are set to POR default settings. VCC1 is starting up and the reset output will be kept LOW and will only be released once VCC1 has crossed  $V_{RT1,r}$  and after  $t_{RD1}$  has elapsed.

In case  $V_S < V_{POR,f}$  an device internal reset will be generated and the SBC is switched OFF and will restart in INIT mode at the next VS rising. This is shown in **Figure 56**.

**Figure 56** Ramp up / down example of Supply Voltage

## Supervision Functions

### 15.4 Undervoltage VS and VSHS

If the supply voltage VS reaches the undervoltage threshold  $V_{S,UV}$  then the SBC does the following measures:

- SPI bit **VS\_UV** is set. No other error bits are set. The bit can be cleared once the condition is not present anymore,
- VCC3 is disabled (see [Chapter 8.2](#)) unless the control bit **VCC3\_VS\_UV\_OFF** is set
- The VCC1 short circuit protection becomes inactive (see [Chapter 15.7](#)). However, the thermal protection of the device remains active.

If the undervoltage threshold is exceeded (VS rising) then functions will be automatically enabled again.

If the supply voltage VSHS passes below the undervoltage threshold ( $V_{SHS,UV}$ ) the SBC does the following measures:

- HS1...4 are acting accordingly to the SPI setting (see [Chapter 9](#))
- LINx: Transmitter and Receiver are disabled during the VSHS undervoltage condition (see [Chapter 11.2.7](#));
- SPI bit **VSHS\_UV** is set. No other error bits are set. The bit can be cleared once the condition is not present anymore,
- VCC1, VCC2, WKx and CAN are not affected by VSHS undervoltage

### 15.5 Overvoltage VSHS

If the supply voltage VSHS reaches the overvoltage threshold ( $V_{SHS,OVD}$ ) the SBC triggers the following measures:

- HS1...4 are acting accordingly to the SPI setting (see [Chapter 9](#))
- SPI bit **VSHS\_OV** is set. No other error bits are set. The bit can be cleared once the condition is not present anymore,
- VCC1, VCC2, VCC3, WKx, LIN and CAN are not affected by VS overvoltage

## 15.6 VCC1 Over-/ Undervoltage and Undervoltage Prewarning

### 15.6.1 VCC1 Undervoltage and Undervoltage Prewarning

A first-level voltage detection threshold is implemented as a prewarning for the microcontroller. The prewarning event is signaled with the bit **VCC1\_WARN**. No other actions are taken.

As described in [Chapter 15.1](#) and [Figure 57](#), a reset will be triggered (RO pulled 'low') when the  $V_{CC1}$  output voltage falls below the selected undervoltage threshold ( $V_{RTX}$ ). The bit **VCC1\_UV** is set and the SBC will enter SBC Restart Mode.

*Note: The **VCC1\_WARN** or **VCC1\_UV** bits are not set in Sleep Mode as  $V_{CC1} = 0V$  in this case*

## Supervision Functions

**Figure 57 VCC1 Undervoltage Timing Diagram**

An additional safety mechanism is implemented to avoid repetitive VCC1 undervoltage resets due to high dynamic loads on VCC1:

- A counter is increased for every consecutive VCC1 undervoltage event (regardless on the selected reset threshold),
- The counter is active in SBC Init-, Normal-, and Stop Mode,
- For  $V_S < V_{S,UV}$  the counter will be stopped in SBC Normal Mode (i.e. the VS UV comparator is always enabled in SBC Normal Mode),
- A 4th consecutive VCC1 undervoltage event will lead to SBC Fail-Safe Mode entry and to setting the bit **VCC1\_UV\_FS**
- This counter is cleared:
  - when SBC Fail-Safe Mode is entered,
  - when the bit **VCC1\_UV** is cleared,
  - when a Soft Reset is triggered.

*Note: It is recommended to clear the VCC1\_UV bit once it was set and detected.*

### 15.6.2 VCC1 Overvoltage

For fail-safe reasons a configurable VCC1 overvoltage detection feature is implemented for SBC Init- and Normal Mode.

In case the  $V_{CC1,OV,r}$  threshold is crossed, the SBC triggers following measures depending on the configuration:

- The bit **VCC1\_OV** is always set;
- If the bit **VCC1\_OV\_RST** is set and **CFG\_P** = '1', then SBC Restart Mode is entered. The FOx outputs are activated. After the reset delay time ( $t_{RD1}$ ), the SBC Restart Mode is left and SBC Normal Mode is resumed even if the VCC1 overvoltage event is still present (see also **Figure 58**). The **VCC1\_OV\_RST** bit is cleared automatically;
- If the bit **VCC1\_OV\_RST** is set and **CFG\_P** = '0', then SBC Fail-Safe Mode is entered and FOx outputs are activated.

*Note: Before entering SBC Stop Mode the bit **VCC1\_OV\_RST** must be set to '0' to avoid unintentional SBC Restart or Fail-Safe Mode entry. The status bit **VCC1\_OV** could be set unintentionally. The reason is*

## Supervision Functions

that external noise could be coupled into the VCC1 supply line. Especially, in case the VCC1 output current in SBC STOP Mode is below the active peak threshold ( $I_{VCC1, I_{peak}}$ ).

Figure 58 VCC1 Overvoltage Timing Diagram

### 15.7 VCC1 Short Circuit and VCC3 Diagnostics

The short circuit protection feature for  $V_{CC1}$  is implemented as follows ( $V_S$  needs to be higher than  $V_{S,UV}$ ):

- If VCC1 is not above the  $V_{RTX}$  within  $t_{VCC1,SC}$  after device power up or after waking from SBC Sleep Mode then the SPI bit **VCC1\_SC** is set, VCC1 is turned OFF, the FOx pins are enabled, **FAILURE** is set and SBC Fail-Safe Mode is entered. The SBC can be activated again via wake on CAN, LINx, WKx.
- The same behavior applies, if  $V_{CC1}$  falls below  $V_{RTX}$  for longer than  $t_{VCC1,SC}$ .

VCC3 diagnosis features are implemented as follows:

- Load Sharing: The external PNP is disabled when  $V_S < V_{S,UV}$  if  $VCC3\_VS\_UV\_OFF = 0$  or when in SBC Stop Mode if **VCC3\_LS\_STP\_ON** = '0'. All other diagnostic features are disabled because they are provided via VCC1.
- Stand-alone configuration: The external PNP is disabled when  $VCC3 < V_{S,UV}$  if  $VCC3\_VS\_UV\_OFF = 0$ . The overcurrent limitation is signalled via the bit **VCC3\_OC** according to the selected shunt resistor, VCC3 undervoltage is signalled via the bit **VCC3\_UV** and the regulator is disabled due to  $V_S$  undervoltage when  $V_{S,UV}$  is reached.

Note: Neither **VCC1\_SC** nor **VCC3\_UV** flags are set during power up of  $V_{CC1}$  or turn on of  $V_{CC3}$  respectively.

### 15.8 VCC2 Undervoltage and VCAN Undervoltage

An undervoltage warning is implemented for VCC2 and VCAN as follows:

- $V_{CC2}$  undervoltage Detection: In case  $V_{CC2}$  will drop below the  $V_{CC2,UV,f}$  threshold, then the SPI bit **VCC2\_UV** is set and can be only cleared via SPI.
- $V_{CAN}$  undervoltage Detection: In case the voltage on  $V_{CAN}$  will drop below the  $V_{CAN\_UV}$  threshold, then the SPI bit **VCAN\_UV** is set and can be only cleared via SPI.

Note: The **VCC2\_UV** flag is not set during turn-on or turn-off of  $V_{CC2}$ .

## Supervision Functions

### 15.9 Thermal Protection

Three independent and different thermal protection features are implemented in the SBC according to the system impact:

- Individual thermal shutdown of specific blocks
- Temperature prewarning of main microcontroller supply VCC1
- SBC thermal shutdown due to VCC1 overtemperature

#### 15.9.1 Individual Thermal Shutdown

As a first-level protection measure the output stages VCC2, CAN, LINx, and HSx are independently switched OFF if the respective block reaches the temperature threshold  $T_{jTSD1}$ . Then the **TSD1** bit is set. This bit can only be cleared via SPI once the overtemperature is not present anymore. Independent of the SBC Mode the thermal shutdown protection is only active if the respective block is ON.

The respective modules behave as follows:

- VCC2: Is switched to OFF and the control bits **VCC2\_ON** are cleared. The status bit **VCC2\_OT** is set. Once the overtemperature condition is not present anymore, then VCC2 has to be configured again by SPI.
- VCC3 as a stand-alone regulator: Is switched to OFF and the control bits **VCC3\_ON** are cleared. The status bit **VCC3\_OT** is set. Once the overtemperature condition is not present anymore VCC3 has to be configured again by SPI. It is recommended to clear the **VCC3\_OT** bit before enabling the regulator again.
- VCC3 in load sharing configuration: in case of overtemperature at VCC3 the bit **VCC3\_OT** is set and VCC3 is switched off. The regulator will be switched on again automatically once the overtemperature event is not present anymore. Also in this case it is recommended to clear the **VCC3\_OT** bit right away.
- CAN: The transmitter is disabled and stays in CAN Normal Mode acting like CAN Receive only mode. The status bits **CAN\_FAIL** = '01' are set. Once the overtemperature condition is not present anymore, then the CAN transmitter is automatically switched on.
- LINx: The transmitter is disabled and stays in LIN Normal Mode acting like LIN Receive only mode. The status bits **LIN1\_FAIL** and **LIN2\_FAIL** respectively are set to '01'. Once the overtemperature condition is not present anymore, then the LIN transmitter is automatically switched on.
- HSx: If one or more HSx switches reach the TSD1 threshold, then all HSx switches are turned OFF and the control bits for HSx are cleared (see registers **HS\_CTRL1** and **HS\_CTRL2**). The status bits HSx\_OC\_OT are set (see register **HS\_OC\_OT\_STAT**). Once the overtemperature condition is not present anymore, then HSx has to be configured again by SPI.

*Note: The diagnosis bits are not cleared automatically and have to be cleared via SPI once the overtemperature condition is not present anymore.*

---

**Supervision Functions****15.9.2 Temperature Prewarning**

As a next level of thermal protection a temperature prewarning is implemented if the main supply VCC1 reaches the thermal prewarning temperature threshold  $T_{JPW}$ . Then the status bit **TPW** is set. This bit can only be cleared via SPI once the overtemperature is not present anymore. Independent of the SBC Mode the thermal prewarning is only active if the VCC1 is ON.

**15.9.3 SBC Thermal Shutdown**

As a highest level of thermal protection a temperature shutdown of the SBC is implemented if the main supply VCC1 reaches the thermal shutdown temperature threshold  $T_{JTSD2}$ . Once a TSD2 event is detected SBC Fail-Safe Mode is entered for  $t_{TSD2}$  to allow the device to cool down. After this time has expired, the SBC will automatically change via SBC Restart Mode to SBC Normal Mode (see also [Chapter 5.1.6](#)).

When a TSD2 event is detected, then the status bit **TSD2** is set. This bit can only be cleared via SPI in SBC Normal Mode once the overtemperature is not present anymore. Independent of the SBC Mode the thermal shutdown is only active if VCC1 is ON.

## Supervision Functions

## 15.10 Electrical Characteristics

**Table 35 Electrical Specification**

$V_S = 5.5\text{ V to }28\text{ V}$ ;  $T_j = -40\text{ °C to }+150\text{ °C}$ ; SBC Normal Mode; all voltages with respect to ground; positive current defined flowing into pin; unless otherwise specified.

| Parameter                                      | Symbol           | Values               |      |                          | Unit | Note or Test Condition                                                      | Number     |

| Deactivation time after thermal shutdown TSD2 | $t_{TSD2}$     | 0.8 | 1   | 1.2 | s  | <sup>3)</sup> | P_15.10.35 |

1) It is ensured that the threshold  $V_{CC1,OV,r}$  is always higher than the highest regulated  $V_{CC1}$  output voltage  $V_{CC1,out42}$ .

2) The reset delay time will start when VCC1 crosses above the selected Vrtx threshold

3) Not subject to production test, tolerance defined by internal oscillator tolerance.

4) This time applies for all failure entries except a device thermal shutdown (TSD2 has a typ. 1s waiting time  $t_{TSD2}$ )

5) Not subject to production test, specified by design.

## Serial Peripheral Interface

## 16 Serial Peripheral Interface

### 16.1 SPI Block Description

The 16-bit wide Control Input Word is read via the data input SDI, which is synchronized with the clock input CLK provided by the microcontroller. The output word appears synchronously at the data output SDO (see [Figure 59](#)).

The transmission cycle begins when the chip is selected by the input CSN (Chip Select Not), LOW active. After the CSN input returns from LOW to HIGH, the word that has been read is interpreted according to the content. The SDO output switches to tristate status (high impedance) at this point, thereby releasing the SDO bus for other use. The state of SDI is shifted into the input register with every falling edge on CLK. The state of SDO is shifted out of the output register after every rising edge on CLK. The SPI of the SBC is not daisy chain capable.

**Figure 59 SPI Data Transfer Timing (note the reversed order of LSB and MSB shown in this figure compared to the register description)**

## Serial Peripheral Interface

### 16.2 Failure Signalization in the SPI Data Output

When the microcontroller sends a wrong SPI command to the SBC, the SBC ignores the information. Wrong SPI commands are either invalid SBC mode commands or commands which are prohibited by the state machine to avoid undesired device or system states (see below). In this case the diagnosis bit '**SPI\_FAIL**' is set and the SPI Write command is ignored (mostly no partial interpretation). This bit can be only reset by actively clearing it via a SPI command.

**Invalid SPI Commands leading to **SPI\_FAIL** are listed below:**

- Illegal state transitions: Going from SBC Stop to SBC Sleep Mode. In this case the SBC enters in addition the SBC Restart Mode;  
Trying to go to SBC Stop or SBC Sleep mode from SBC Init Mode. In this case SBC Normal Mode is entered;
- Uneven parity in the data bit of the **WD\_CTRL** register. In this case the watchdog trigger is ignored or the new watchdog settings are ignored respectively;
- In SBC Stop Mode: attempting to change any SPI settings, e.g. changing the watchdog configuration, PWM settings and HS configuration settings during SBC Stop Mode, etc.;  
the SPI command is ignored in this case;  
only WD trigger, returning to Normal Mode, triggering a SBC Soft Reset, and Read & Clear status registers commands are valid SPI commands in SBC Stop Mode;
- When entering SBC Stop Mode and **WK\_STAT\_1** and **WK\_STAT\_2** are not cleared; **SPI\_FAIL** will not be set but the INT pin will be triggered;
- Changing from SBC Stop to Normal Mode and changing the other bits of the **M\_S\_CTRL** register. The other modifications will be ignored;
- SBC Sleep Mode: attempt to go to Sleep Mode when all bits in the **BUS\_CTRL\_1**, **BUS\_CTRL\_2** and **WK\_CTRL\_2** registers are cleared. In this case the **SPI\_FAIL** bit is set and the SBC enters Restart Mode.  
Even though the Sleep Mode command is not entered in this case, the rest of the command (e.g modifying VCC2 or VCC3) is executed and the values stay unchanged during SBC Restart Mode;  
Note: At least one wake source must be activated in order to avoid a deadlock situation in SBC Sleep Mode, i.e. the SBC would not be able to wake up anymore.  
If the only wake source is a timer and the timer is OFF then the SBC will wake immediately from Sleep Mode and enter Restart Mode;  
No failure handling is done for the attempt to go to SBC STOP Mode when all bits in the registers **BUS\_CTRL\_1**, **BUS\_CTRL\_2** and **WK\_CTRL\_2** are cleared because the microcontroller can leave this mode via SPI;
- If VCC3 load sharing **VCC3\_LS** is enabled and the microcontroller tries to clear the bit, then the rest of the command executed but **VCC3\_LS** will remain set;
- Attempt to enter SBC Sleep Mode if WK\_MEAS is set to '1' and only WK1\_EN or WK2\_EN are set as wake sources. Also in this case the **SPI\_FAIL** bit is set and the SBC enters Restart Mode;
- Setting a longer or equal on-time than the timer period of the respective timer;
- SDI stuck at HIGH or LOW, e.g. SDI received all '0' or all '1';

*Note: There is no SPI fail information for unused addresses.*

#### **Signalization of the ERR Flag (high active) in the SPI Data Output (see Figure 59):**

The ERR flag presents an additional diagnosis possibility for the SPI communication. The ERR flag is being set for following conditions:

- in case the number of received SPI clocks is not 0 or 16,
- in case RO is LOW and SPI frames are being sent at the same time.

## Serial Peripheral Interface

*Note: In order to read the SPI ERR flag properly, CLK must be low when CSN is triggered, i.e. the ERR bit is not valid if the CLK is high on a falling edge of CSN*

### **The number of received SPI clocks is not 0 or 16:**

The number of received input clocks is supervised to be 0- or 16 clock cycles and the input word is discarded in case of a mismatch (0 clock cycle to enable ERR signalization). The error logic also recognizes if CLK was high during CSN edges. Both errors - 0 bit and 16 bit CLK mismatch or CLK high during CSN edges - are flagged in the following SPI output by a "HIGH" at the data output (SDO pin, bit ERR) before the first rising edge of the clock is received. The complete SPI command is ignored in this case.

### **RO is LOW and SPI frames are being sent at the same time:**

The ERR flag will be set when the RO pin is triggered (during SBC Restart) and SPI frames are being sent to the SBC at the same time. The behavior of the ERR flag will be signalized at the next SPI command for below conditions:

- if the command begins when RO is HIGH and it ends when RO is LOW,
- if a SPI command will be sent while RO is LOW,
- If a SPI command begins when RO is LOW and it ends when RO is HIGH.

and the SDO output will behave as follows:

- always when RO is LOW then SDO will be HIGH,
- when a SPI command begins with RO is LOW and ends when RO is HIGH, then the SDO should be ignored because wrong data will be sent.

*Note: It is possible to quickly check for the ERR flag without sending any data bits. i.e. only the CSN is pulled low and SDO is observed - no SPI Clocks are sent in this case*

*Note: The ERR flag could also be set after the SBC has entered SBC Fail-Safe Mode because the SPI communication is stopped immediately.*

## Serial Peripheral Interface

### 16.3 SPI Programming

For the TLE9263-3BQX, 7 bits are used for the address selection (BIT6...0). Bit 7 is used to decide between Read Only and Read & Clear for the status bits, and between Write and Read Only for configuration bits. For the actual configuration and status information, 8 data bits (BIT15...8) are used.

Writing, clearing and reading is done byte wise. The SPI status bits are not cleared automatically and must be cleared by the microcontroller, e.g. if the TSD2 was set due to overtemperature. The configuration bits will be partially automatically cleared by the SBC - please refer to the individual registers description for detailed information. During SBC Restart Mode the SPI communication is ignored by the SBC, i.e. it is not interpreted.

There are two types of SPI registers:

- Control registers: Those are the registers to configure the SBC, e.g. SBC mode, watchdog trigger, etc
- Status registers: Those are the registers where the status of the SBC is signalled, e.g. wake events, warnings, failures, etc.

For the status registers, the requested information is given in the same SPI command in DO.

For the control registers, also the status of the respective byte is shown in the same SPI command. However, if the setting is changed this is only shown with the next SPI command (it is only valid after CSN high) of the same register.

The SBC status information from the SPI status registers, is transmitted in a compressed way with each SPI response on SDO in the so called Status Information Field register (see also [Figure 60](#)). The purpose of this register is to quickly signal the information to the microcontroller if there was a change in one of the SPI status registers. In this way, the microcontroller does not need to read constantly all the SPI status registers but only those registers, which were changed.

Each bit in the Status Information Field represents a SPI status register (see [Table 36](#)). As soon as one bit is set in one of the status registers, then the respective bit in the Status Information Field register will be set. The register [WK\\_LVL\\_STAT](#) is not included in the status Information field. This is listed in [Table 36](#).

For Example if bit 0 in the Status Information Field is set to 1, one or more bits of the register 100 0001 ([SUP\\_STAT\\_1](#)) is set to 1. Then this register needs to be read in a second SPI command. The bit in the Status Information Field will be set to 0 when all bits in the register 100 0001 are set back to 0.

**Table 36 Status Information Field**

| Bit in Status Information Field | Corresponding Address Bit | Status Register Description                                                                       |

Figure 60 SPI Operation Mode

## Serial Peripheral Interface

### 16.4 SPI Bit Mapping

The following figures show the mapping of the registers and the SPI bits of the respective registers.

The Control Registers '000 0000' to '001 1110' are Read/Write Register. Depending on bit 7 the bits are only read (setting bit 7 to '0') or also written (setting bit 7 to '1'). The new setting of the bit after write can be seen with a new read / write command.

The registers '100 0000' to '111 1110' are Status Registers and can be read or read with clearing the bit (if possible) depending on bit 7. To clear a Data Byte of one of the Status Registers bit 7 must be set to 1. The registers **WK\_LVL\_STAT**, and **FAM\_PROD\_STAT**, **SWK\_OSC\_CAL\_H\_STAT**, **SWK\_OSC\_CAL\_L\_STAT**, **SWK\_STAT**, **SWK\_ECNT\_STAT**, **SWK\_CDR\_STAT1**, **SWK\_CDR\_STAT2** are an exception as they show the actual voltage level at the respective WK pin (LOW/HIGH), or a fixed family/ product ID respectively and can thus not be cleared. It is recommended for proper diagnosis to clear respective status bits for wake events or failure. However, in general it is possible to enable drivers without clearing the respective failure flags.

When changing to a different SBC Mode, certain configurations bits will be cleared automatically or modified:

- The SBC Mode bits are updated to the actual status, e.g. when returning to Normal Mode
- When changing to a low-power mode (Stop/Sleep), the diagnosis bits of the switches and transceivers are not cleared. FOx will stay activated if it was triggered before.
- When changing to SBC Stop Mode, the CAN and LIN control bits will not be modified.
- When changing to SBC Sleep Mode, the CAN and LIN control bits will be modified if they were not OFF or wake capable before.
- HSx, VCC2 and VCC3 will stay on when going to Sleep-/Stop Mode (configuration can only be done in Normal Mode). Diagnosis is active (OC, OL, OT). In case of a failure the switch is turned off and no wake-up is issued
- The configuration bits for HSx and VCC2 in stand-alone configuration are cleared in SBC Restart Mode. FOx will stay activated if it was triggered before. Depending on the respective configuration, CAN/LIN transceivers will be either OFF, woken or still wake capable.

**Note:** *The detailed behavior of the respective SPI bits and control functions is described in [Chapter 16.5](#), [Chapter 16.6](#) and in the respective module chapter. The bit type be marked as 'rwh' in case the SBC will modify respective control bits.*

Figure 62 TLE9263-3BQX SPI Bit Mapping including Selective Wake

---

**Serial Peripheral Interface****16.5 SPI Control Registers**

READ/WRITE Operation (see also [Chapter 16.3](#)):

- The 'POR / Soft Reset Value' defines the register content after POR or SBC Reset.
- The 'Restart Value' defines the register content after SBC Restart, where 'x' means the bit is unchanged.
- One 16-bit SPI command consist of two bytes:
  - the 7-bit address and one additional bit for the register access mode and
  - following the data byteThe numbering of following bit definitions refers to the data byte and correspond to the bits D0...D7 and to the SPI bits 8...15 (see also figure before).
- There are three different bit types:
  - 'r' = READ: read only bits (or reserved bits)
  - 'rw' = READ/WRITE: readable and writable bits
  - 'rwh' = READ/WRITE/Hardware: readable/writable bits, which can also be modified by the SBC hardware
- Reserved bits are marked as "Reserved" and always read as "0". The respective bits shall also be programmed as "0".
- Reading a register is done byte wise by setting the SPI bit 7 to "0" (= Read Only).
- Writing to a register is done byte wise by setting the SPI bit 7 to "1".
- SPI control bits are in general not cleared or changed automatically. This must be done by the microcontroller via SPI programming. Exceptions to this behavior are stated at the respective register description and the respective bit type is marked with a 'h' meaning that the SBC is able to change the register content.

The registers are addressed wordwise.

## Notes

1. It is not possible to change from Stop to Sleep Mode via SPI Command. See also the State Machine Chapter
2. After entering SBC Restart Mode, the MODE bits will be automatically set to SBC Normal Mode. The VCC2\_ON bits will be automatically set to OFF after entering SBC Restart Mode and after OT.
3. The SPI output will always show the previously written state with a Write Command (what has been programmed before)

| CFG            | 0    | rw   | <b>Configuration Select (see also <a href="#">Table 5</a>)</b><br>0B , Depending on hardware configuration, SBC Restart or Fail-Safe Mode is reached after the 2. watchdog trigger failure (=default) - Config 3/4<br>1B , Depending on hardware configuration, SBC Restart or Fail-Safe Mode is reached after the 1. watchdog trigger failure - Config 1/2 |

## Notes

1. Clearing the FO\_ON bit will not disable the FOx outputs for the case a failure occurred which triggered the FOx outputs. In this case the FOx outputs have to be disabled by clearing the FAILURE bit.

---

**Serial Peripheral Interface**

*If the FO\_ON bit is set by the software then it will be cleared by the SBC after SBC Restart Mode was entered and the FOx outputs will be disabled. See also [Chapter 14](#) for FOx activation and deactivation.*

- 2. After triggering a SBC Soft Reset the bits VCC3\_V\_CFG and VCC3\_LS are not reset if they were set before, i.e. it stays unchanged, which is stated by the 'y' in the POR / Soft Reset Value. POR value: 0000 0000 and Soft Reset value: xx00 x00x*
- 3. VCC3\_LS\_STP\_ON: Is a combination of load sharing and VCC1 active peak in Stop mode*

## Notes

- Changes in the bits **LIN\_FLASH** and **LIN\_LSM** will be effective immediately once CSN goes to '1'.
- The reset values for the LIN and CAN transceivers are marked with 'y' because they will vary depending on the cause of change - see below.
- see **Figure 31** and **Figure 38** for detailed state changes of LIN and CAN Transceiver for different SBC modes.
- The bit CAN\_2 is not modified by the SBC but can only be changed by the user. Therefore, the access type is 'rw' compared to bits CAN\_0 and CAN\_1.
- In case SYSERR = 0 and the CAN transceiver is configured to 'x11' while going to SBC Sleep Mode, it will be automatically set to wake capable ('x01'). The SPI bits will be changed to wake capable. If configured to 'x10' and SBC Sleep Mode is entered, then the transceiver is set to wake capable, while it will stay in Receive Only Mode when it had been configured to 'x10' when going to SBC Stop Mode. If it had been configured to wake

## Serial Peripheral Interface

capable or OFF then the mode will remain unchanged. The Receive Only Mode has to be selected by the user before entering SBC Stop Mode. Please refer to [Chapter 5.4.4](#) for detailed information on the Selective Wake mode changes.

6. Failure Handling Mechanism: When the device enters Fail-Safe Mode due to a failure (TSD2, WD-Failure,...), then the wake registers **BUS\_CTRL\_1**, **BUS\_CTRL\_2** and **WK\_CTRL\_2** are reset to following values (=wake sources) 'xxx0 1001', '0000 0001' and 'x0x0 0111' in order to ensure that the device can be woken again.

## Notes

1. WK\_MEAS is by default configured for standard WK functionality (WK1 and WK2). The bits WK1\_EN and WK2\_EN are ignored in case WK\_MEAS is activated. If the bit is set to '1' then the measurement function is enabled during Normal Mode & the bits WK1\_EN and WK2\_EN are ignored. The bits WK1/"\_LVL bits need to be ignored as well.
2. The wake sources LINx and CAN are selected in the register **BUS\_CTRL\_1** and **BUS\_CTRL\_2** by setting the respective bits to 'wake capable'
3. Failure Handling Mechanism: When the device enters Fail-Safe Mode due to a failure (TSD2, WD-Failure,...), then the wake registers **BUS\_CTRL\_1**, **BUS\_CTRL\_2** and **WK\_CTRL\_2** are reset to following values (=wake sources) 'xxx0 1001', '0000 0001' and 'x0x0 0111' in order to ensure that the device can be woken again.

## Notes

1. A timer must be first assigned and is then automatically activated as soon as the on-time is configured.
2. If cyclic sense is selected and the HS switches are cleared during SBC Restart Mode, then also the timer settings (period and on-time) are cleared to avoid incorrect switch detection.
3. In case the timer are set as wake sources and cyclic sense is running, then both cyclic sense and cyclic wake will be active at the same time.

| SYS_STAT | 7:0  | rw   | <b>System Status Control Byte (bit0=LSB; bit7=MSB)</b><br>Dedicated byte for system configuration, access only by microcontroller. Cleared after power up and Soft Reset |

**Notes**

1. The **SYS\_STATUS\_CTRL** register is an exception for the default values, i.e. it will keep its configured value also after a Soft Reset.
2. This byte is intended for storing system configurations of the ECU by the microcontroller and is only accessible in SBC Normal Mode. The byte is not accessible by the SBC and is also not cleared after Fail-Safe or SBC Restart Mode. It allows the microcontroller to quickly store system configuration without losing the data.

## Serial Peripheral Interface

| CFG_VAL    | 0    | rwh  | <b>SWK Configuration valid</b><br>0B , Configuration is not valid (SWK not possible)<br>1B , SWK configuration valid, needs to be set to enable SWK |

## Notes

1. TRIM\_EN unlocks the oscillation calibration mode. Only the bit combination '11' is the valid unlock. The pin TXDCAN is used for oscillator synchronisation (trimming).
2. The microcontroller needs to validate the SWK configuration and set 'CFG\_VAL' to '1'. The SBC will only enable SWK if CFG\_VAL' to '1'. The bit will be cleared automatically by the SBC after a wake up or POR or if a SWK configuration data is changed by the microcontroller.
3. CANTO bit will only be updated inside BUS\_STAT while CAN\_2 is set. Therefore, an interrupt is only signaled upon occurrence of CANTO while CAN\_2 (SWK is enabled) is set in SBC Normal and Stop Mode.
4. TRIM\_EN also unlocks the writing to the SWK\_OPT\_CTRL register in order to enable the alternate low-power Receiver for Selective wake to optimize the quiescent current consumption. Only the bit combination '11' unlocks the calibrations / configurations.

| DLC      | 3:0  | rw   | <b>Payload length in number of bytes</b><br>0000B, Frame Data Length = 0 or cleared<br>0001B, Frame Data Length = 1<br>0010B, Frame Data Length = 2<br>0011B, Frame Data Length = 3<br>0100B, Frame Data Length = 4<br>0101B, Frame Data Length = 5<br>0110B, Frame Data Length = 6<br>0111B, Frame Data Length = 7<br>from 1000B to 1111B Frame Data Length = 8 |

**Note:** The number of bytes in the data field has to be indicated by the DLC. The DLC consists of four bits. The admissible number of data bytes for a data frame ranges from zero to eight. DLCs in the range of zero to seven shall indicate data fields of length of zero to seven bytes. DLCs in the range from eight to fifteen indicate data fields of length of eight byte. The configured DLC value has to match bit by bit with the DLC in the received wake-up frame (refer also to [Chapter 5.4.2.3](#)).

## Serial Peripheral Interface

| Field       | Bits | Type | Description                                                                                                                                                               |
|-------------|------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Reserved    | 7:6  | r    | Reserved, always reads as 0                                                                                                                                               |
| DIS_ERR_CNT | 5    | rwh  | <b>Error Counter Disable Function</b><br>0B , Error Counter is enabled during SWK<br>1B , Error counter is disabled during SWK only if CAN_FD_EN = '1'                    |
| RX_FILT_BYP | 4    | rw   | <b>RX Receiver Filter Bypass</b><br>0B , RX Filter not bypassed<br>1B , RX Filter bypassed                                                                                |
| FD_FILTER   | 3:1  | rw   | <b>CAN FD Dominant Filter Time</b><br>000B , 50 ns<br>001B , 100 ns<br>010B , 150 ns<br>011B , 200 ns<br>100B , 250 ns<br>101B , 300 ns<br>110B , 350 ns<br>111B , 775 ns |
| CAN_FD_EN   | 0    | rw   | <b>Enable CAN FD Tolerant Mode</b><br>0B , CAN FD Tolerant Mode disabled<br>1B , CAN FD Tolerant Mode enabled                                                             |

Note: The bit **RX\_FILT\_BYP** is bypassing the analog filter in the CAN receiver path; The **FD\_FILTER** is not in the analog path of the CAN receiver and is not bypassed.

Note: **DIS\_ERR\_CNT** is cleared by the SBC at tsilence expiration.

## Serial Peripheral Interface

## 16.5.3 Selective Wake Trimming and Calibration Control Registers

## SWK\_OSC\_TRIM\_CTRL

SWK Oscillator Trimming Register (Address 011 1000<sub>B</sub>)POR / Soft Reset Value: xxxx xxxx<sub>B</sub>; Restart Value: xxxx xxxx<sub>B</sub>

|            |            |            |            |            |            |            |            |
|------------|------------|------------|------------|------------|------------|------------|------------|
| 7          | 6          | 5          | 4          | 3          | 2          | 1          | 0          |
| TRIM_OSC_7 | TRIM_OSC_6 | TRIM_OSC_5 | TRIM_OSC_4 | TRIM_OSC_3 | TRIM_OSC_2 | TRIM_OSC_1 | TRIM_OSC_0 |
| rw         | rw         | rw         | rw         | rw         | rw         | rw         | rw         |

| Field    | Bits | Type | Description                                                                    |
|----------|------|------|--------------------------------------------------------------------------------|
| TRIM_OSC | 7:0  | rw   | Oscillator trimming (bit0=LSB; bit7=MSB);<br>(only writable if TRIM_EN = '11') |

Note: TRIM\_OSC[0:4] represent the 32-steps fine trimming range with a monotonous behavior from slower to faster frequency. The step width is ~0.25MHz.  
 TRIM\_OSC[5:7] are modifying the oscillator temperature coefficient. It is strongly recommended to not change these values.  
 Due to CDR functionality, it is not required to change these values.

## SWK\_OPT\_CTRL

Selective Wake Options Register (Address 011 1001<sub>B</sub>)POR / Soft Reset Value: 000x xxxx<sub>B</sub>; Restart Value: x00x xxxx<sub>B</sub>

|           |          |          |             |             |             |            |            |
|-----------|----------|----------|-------------|-------------|-------------|------------|------------|
| 7         | 6        | 5        | 4           | 3           | 2           | 1          | 0          |
| RX_WK_SEL | Reserved | Reserved | TRIM_OSC_12 | TRIM_OSC_11 | TRIM_OSC_10 | TRIM_OSC_9 | TRIM_OSC_8 |
| rw        | r        | rw       | rw          | rw          | rw          | rw         | rw         |

| Field     | Bits | Type | Description                                                                                                                                                    |
|-----------|------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RX_WK_SEL | 7    | rw   | <b>SWK Receiver selection (only accessible if TRIM_EN = '11')</b><br>0B , Standard Receiver selected during SWK<br>1B , Low-Power Receiver selected during SWK |
| Reserved  | 6:5  | r    | <b>Reserved, always reads as 0</b>                                                                                                                             |
| TRIM_OSC  | 4:0  | rw   | <b>Oscillator trimming (bit8=LSB; bit12=MSB);<br/>(only writable if TRIM_EN = '11')</b>                                                                        |

Note: The bit RX\_WK\_SEL is used to select the respective receiver during Selective Wake operation. To reduce the quiescent current during Frame Detect Mode it is recommended to select the Low-Power Receiver, i.e. RX\_WK\_SEL = '1'.  
 Important: If the RX\_WK\_SEL bit is changed, then it must be ensured that the values of TRIM\_OSC [8:12] bits remain unchanged to avoid a change of oscillator frequency.

## Serial Peripheral Interface

*Note:*  $TRIM\_OSC[8:12]$  represent the 32-steps coarse trimming range, which is not monotonous.  
It is not recommended to change these values.

### SWK\_OSC\_CAL\_H\_STAT

**Serial Peripheral Interface****16.6 SPI Status Information Registers**

READ/CLEAR Operation (see also [Chapter 16.3](#)):

- One 16-bit SPI command consist of two bytes:
  - the 7-bit address and one additional bit for the register access mode and
  - following the data byteThe numbering of following bit definitions refers to the data byte and correspond to the bits D0...D7 and to the SPI bits 8...15 (see also figure).
- There are two different bit types:
  - 'r' = READ: read only bits (or reserved bits)
  - 'rc' = READ/CLEAR: readable and clearable bits
- Reading a register is done byte wise by setting the SPI bit 7 to "0" (= Read Only)
- Clearing a register is done byte wise by setting the SPI bit 7 to "1"
- SPI status registers are in general not cleared or changed automatically (an exception are the [WD\\_FAIL](#) bits). This must be done by the microcontroller via SPI command

The registers are addressed wordwise.

## Notes

1. The MSB of the POR/Soft Reset value is marked as 'y': the default value of the POR bit is set after Power-on reset (POR value = 1000 0000). However it will be cleared after a SBC Soft Reset command (Soft Reset value = 0000 0000).
2. During Sleep Mode, the bits VCC1\_SC, VCC1\_OV and VCC1\_UV will not be set when VCC1 is off
3. The VCC1\_UV bit is never updated in SBC Restart Mode, in SBC Init Mode it is only updated after RO was released for the first time, it is always updated in SBC Normal and Stop Mode, and it is always updated in any SBC modes in a VCC1\_SC condition (after VCC1\_UV = 1 for >4ms).

## Notes

- The bits **DEV\_STAT** show the status of the device before it went through Restart. Either the device came from regular Sleep Mode ('10') or a failure ('01' - SBC Restart or SBC Fail-Safe Mode: WD fail, TSD2 fail, VCC1\_UV fail or VCC1\_OV if bit **VCC1\_OV\_RST** is set) occurred. Failure is also an illegal command from SBC Stop to SBC Sleep Mode or going to SBC Sleep Mode without activation of any wake source. Coming from SBC Sleep Mode ('10') will also be shown if there was a trial to enter SBC Sleep Mode without having cleared all wake flags before.
- The **WD\_FAIL** bits are configured as a counter and are the only status bits, which are cleared automatically by the SBC. They are cleared after a successful watchdog trigger and when the watchdog is stopped (also in SBC Sleep and Fail-Safe Mode unless it was reached due to a watchdog failure). See also **Chapter 14.1**.
- The **SPI\_FAIL** bit is cleared only by SPI command
- In case of Config 2/4 the WD\_Fail counter is frozen in case of WD trigger failure until a successful WD trigger.
- If CFG = '0' then a 1st watchdog failure will not trigger the FO outputs or the FAILURE bit but only force the SBC into SBC Restart Mode.

## Notes

- CAN and LIN Recovery Conditions:
  - TXD Time Out: TXD goes HIGH or transmitter is set to wake capable or switched off;
  - Bus dominant time out: Bus will become recessive or transceiver is set to wake capable or switched off.
  - Supply undervoltage: as soon as the threshold is crossed again, i.e.  $V_{SHS} > V_{S\_UV}$  for LIN and  $V_{CAN} > V_{CAN\_UV}$  for CAN
  - In all cases (also for TSD shutdown): to enable the Bus transmission again, TXD needs to be HIGH for a certain time (transmitter enable time).
- The VCAN\_UV comparator is enabled if the mode bit CAN\_1 = '1', i.e. in CAN Normal or CAN Receive Only Mode.

---

**Serial Peripheral Interface**

3. *CANTO will be set only if CAN2 = 1 (=SWK Mode enabled). It will be set as soon as CANSIL was set and will stay set even in CANSIL it is reset. An interrupt is issued in SBC Stop- and SBC Normal Mode as soon as CANTO is set and the interrupt is not masked out, i.e. CANTO\_MASK must be set to 1.*
4. *The SYSERR Flag is set in case of a configuration error and in case of an error counter overflow ( $n > 32$ ). It is only updated if SWK is enabled (CAN\_2 = '1'). See also [Chapter 5.4.3](#).*
5. *CANTO is set asynchronously to the INT pulse. In order to prevent undesired clearing of CANTO and thus possibly missing this interrupt, the bit will be prevented from clearing (i.e. cannot be cleared) until the next falling edge of INT.*

| WK2_LVL     | 1    | r    | <b>Status of WK2</b><br>0B , Low Level (=0)<br>1B , High Level (=1)                                                                                                   |
| WK1_LVL     | 0    | r    | <b>Status of WK1</b><br>0B , Low Level (=0)<br>1B , High Level (=1)                                                                                                   |

**Note:** GPIOx\_LVL is updated in SBC Normal and Stop Mode if configured as wake input, low-side switch or high-side switch.  
 In cyclic sense or wake mode, the registers contain the sampled level, i.e. the registers are updated after every sampling. The GPIOs are not capable of cyclic sensing.  
 If selected as GPIO then the respective level is shown even if configured as low-side or high-side.

1) Not subject to production test; specified by design

2) Applies to all mode changes triggered via SPI commands

**Figure 63 SPI Timing Diagram**

**Note:** Numbers in drawing correlate to the last 2 digits of the Number field in the Electrical Characteristics table.

## Application Information

## 17 Application Information

## 17.1 Application Diagram

**Note:** The following information is given as a hint for the implementation of the device only and shall not be regarded as a description or warranty of a certain functionality, condition or quality of the device.

Figure 64 Simplified Application Diagram

## Application Information

*Note: Unused outputs are recommended to be left unconnected on the application board. If unused output pins are routed to an external connector which leaves the ECU, then these pins should have provision for a zero ohm jumper (depopulated if unused) or ESD protection.*

| <b>Capacitances</b> |                       |                                                                                                                                                                               |
| C1                  | 68 $\mu$ F            | Buffering capacitor to cut off battery spikes, depending on application                                                                                                       |
| C2                  | 100nF                 | EMC, blocking capacitor                                                                                                                                                       |
| C3                  | 22 $\mu$ F            | Buffering capacitor to cut off battery spikes from VSHS as separate supply input; Depending on application, only needed if VSHS is not connected to VS;                       |
| C4                  | 2.2 $\mu$ F low ESR   | As required by application, min. 470nF for stability and max. 68 $\mu$ F recommended                                                                                          |
| C5                  | 100nF ceramic         | Spike filtering, improve stability of supply for microcontroller; not needed for SBC                                                                                          |
| C6                  | 2.2 $\mu$ F low ESR   | Blocking capacitor, min. 470nF for stability; if used for CAN supply place a 100nF ceramic capacitor in addition very close to VCAN pin for optimum EMC behavior              |
| C7                  | 33nF                  | As required by application, mandatory protection for off-board connections                                                                                                    |
| C8                  | 33nF                  | As required by application, mandatory protection for off-board connections                                                                                                    |
| C17                 | 47pF                  | Only required in case of off-board connection to optimize EMC behavior, place close to pin                                                                                    |
| C18                 | 47pF                  | Only required in case of off-board connection to optimize EMC behavior, place close to pin                                                                                    |
| C9                  | 10nF                  | Spike filtering, as required by application, mandatory protection for off-board connections (see also Simplified Application Diagram with the Alternate Measurement Function) |
| C10                 | 10nF                  | Spike filtering, as required by application, mandatory protection for off-board connections                                                                                   |
| C11                 | 10nF                  | Spike filtering, as required by application, mandatory protection for off-board connections                                                                                   |
| C12                 | 4.7nF / OEM dependent | Split termination stability                                                                                                                                                   |
| C13                 | 10 $\mu$ F low ESR    | Stability of VCC3, ceramic capacitor, e.g. Murata 10 $\mu$ F/10 V GCM31CR71A106K64L or 2x 4.7 $\mu$ F/10 V                                                                    |
| C14                 | 47nF                  | Only required in case of off-board connection to optimize EMC behavior, place close to connector                                                                              |
| C15                 | 1nF / OEM dependent   | LIN master termination                                                                                                                                                        |
| C16                 | 1nF / OEM dependent   | LIN master termination                                                                                                                                                        |
| <b>Resistances</b>  |                       |                                                                                                                                                                               |
| R1                  | 10k $\Omega$          | Wetting current of the switch, as required by application                                                                                                                     |

## Application Information

**Table 40 Bill of Material for Simplified Application Diagram (cont'd)**

| Ref. | Typical Value                                                                    | Purpose / Comment                                                                                                                                                                                            |
|------|----------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| R2   | 10k $\Omega$                                                                     | Limit the WK pin current, e.g. for ISO pulses                                                                                                                                                                |

| R8   | depending on LED config.                                                         | LED current limitation, as required by application                                                                                                                                                           |
| R9   | 47k $\Omega$                                                                     | Selection of hardware configuration 1/3, i.e. in case of WD failure SBC Restart Mode is entered.<br>If not connected, then hardware configuration 2/4 is selected                                            |
| R10  | 60 $\Omega$ / OEM dependent                                                      | CAN bus termination                                                                                                                                                                                          |
| R11  | 60 $\Omega$ / OEM dependent                                                      | CAN bus termination                                                                                                                                                                                          |
| R12  | 1 $\Omega$ shunt, depending on required current limitation or load sharing ratio | Sense shunt for ICC3 current limitation (configured to typ. 235mA with 1 $\Omega$ shunt) for stand-alone configuration;<br>Setting of load sharing ratio (here ICC3/ICC1 = 1) in load sharing configuration. |
| R13  | 1k $\Omega$ / OEM dependent                                                      | LIN master termination (if configured as a LIN master)                                                                                                                                                       |
| R14  | 1k $\Omega$ / OEM dependent                                                      | LIN master termination (if configured as a LIN master)                                                                                                                                                       |
| R15  | 10k $\Omega$                                                                     | WK1 pin current limitation, e.g. for ISO pulses, for alternate measurement function (see also Simplified Application Diagram with the Alternate Measurement Function)                                        |
| R16  | depending on application and microcontroller                                     | Voltage Divider resistor to adjust measurement voltage to microcontroller ADC input range (see also Simplified Application Diagram with the Alternate Measurement Function)                                  |
| R17  | depending on application and microcontroller                                     | Voltage Divider resistor to adjust measurement voltage to microcontroller ADC input range (see also Simplified Application Diagram with the Alternate Measurement Function)                                  |

### Active Components

|         |                          |                                                                                                                    |
|---------|--------------------------|--------------------------------------------------------------------------------------------------------------------|
| D1      | e.g. BAS 3010A, Infineon | Reverse polarity protection for VS supply pins                                                                     |
| D2      | e.g. BAS 3010A, Infineon | Reverse polarity protection for VSHS supply pin; if separate supplies are not needed, then connect VSHS to VS pins |
| D3      | LED                      | As required by application, configure series resistor accordingly                                                  |
| D4      | LED                      | As required by application, configure series resistor accordingly                                                  |
| D5      | e.g. BAS70               | Requested by LIN standard; reverse polarity protection of network                                                  |
| D6      | e.g. BAS70               | Requested by LIN standard; reverse polarity protection of network                                                  |
| T1      | e.g. BCR191W             | High active FO control                                                                                             |
| T2      | BCP 52-16, Infineon      | Power element of VCC3, current limit or load sharing ratio to be configured via shunt                              |
|         | MJD 253, ON Semi         | Alternative power element of VCC3                                                                                  |
| $\mu$ C | e.g. TC2xxx              | Microcontroller                                                                                                    |

## Application Information

**Note:** This is a simplified example of an application circuit. The function must be verified in the real application.

**Figure 65** Simplified Application Diagram with the Alternate Measurement Function via WK1 and WK2

**Note:** This is a very simplified example of an application circuit. The function must be verified in the real application. WK1 must be connected to signal to be measured and WK2 is the output to the microcontroller supervision function. The maximum current into WK1 must be <500 μA. The minimum current into WK1 should be >5 μA to ensure proper operation.

## Application Information

**Figure 66** Hint for Increasing the Robustness of pin FO3/TEST during Debugging or Programming

## Application Information

### 17.2 ESD Tests

*Note: Tests for ESD robustness according to IEC61000-4-2 “gun test” (150pF, 330Ω) has been performed. The results and test conditions are available in a test report. The target values for the test are listed in [Table 41](#) below.*

**Table 41 ESD “Gun Test”**

| Performed Test                                                     | Result | Unit | Remarks                        |
|--------------------------------------------------------------------|--------|------|--------------------------------|
| ESD at pin CANH, CANL, LIN, VS, WK1..3, HSx, VCC2, VCC3 versus GND | >6     | kV   | <sup>1)2)</sup> positive pulse |
| ESD at pin CANH, CANL, LIN, VS, WK1..3, HSx, VCC2, VCC3 versus GND | < -6   | kV   | <sup>1)2)</sup> negative pulse |

- 1) ESD Test “Gun Test” is specified with external components for pins VS, WK1..3, HSx, VCC3 and VCC2. See the application diagram in [Chapter 17.1](#) for more information.
- 2) ESD susceptibility “ESD GUN” according LIN EMC 1.3 Test Specification, Section 4.3 (IEC 61000-4-2). Tested by external test house (IBEE Zwickau, EMC Test report Nr. 04-01-17)

EMC and ESD susceptibility tests according to SAE J2962-2 (2010) have been performed. Tested by external test house (UL LLC).

Application Information

17.3 Thermal Behavior of Package

Below figure shows the thermal resistance ( $R_{th\_JA}$ ) of the device vs. the cooling area on the bottom of the PCB for  $T_a = 85^{\circ}\text{C}$ . Every line reflects a different PCB and thermal via design.

Figure 67 Thermal Resistance ( $R_{th\_JA}$ ) vs. Cooling Area

## Application Information

**Figure 68 Board Setup**

Board setup is defined according to JESD 51-2,-5,-7.

Board: 76.2x114.3x1.5mm<sup>3</sup> with 2 inner copper layers (35µm thick), with thermal via array under the exposed pad contacting the first inner copper layer and 300mm<sup>2</sup> cooling area on the bottom layer (70µm).

## Package Outlines

## 18 Package Outlines

Figure 69 PG-VQFN-48-31

**Note:** Dimensions in mm.  
The tie bars have an internal connection to the exposed pad.  
For assembly recommendations please also refer to the documents "Recommendations for Board Assembly (VQFN and IQFN)" and "VQFN48 Layout Hints" on the Infineon website ([www.infineon.com](http://www.infineon.com)).

The PG-VQFN-48-31 package is a leadless exposed pad power package featuring Lead Tip Inspection (LTI) to support Automatic Optical Inspection (AOI).

**Green Product (RoHS compliant)**

To meet the world-wide customer requirements for environmentally friendly products and to be compliant with government regulations the device is available as a green product. Green products are RoHS-Compliant (i.e Pb-free finish on leads and suitable for Pb-free soldering according to IPC/JEDEC J-STD-020).

For further information on alternative packages, please visit our website:  
<http://www.infineon.com/packages>.

#### IMPORTANT NOTICE

The information given in this document shall in no event be regarded as a guarantee of conditions or characteristics ("Beschaffenheitsgarantie").

With respect to any examples, hints or any typical values stated herein and/or any information regarding the application of the product, Infineon Technologies hereby disclaims any and all warranties and liabilities of any kind, including without limitation warranties of non-infringement of intellectual property rights of any third party.

In addition, any information given in this document is subject to customer's compliance with its obligations stated in this document and any applicable legal requirements, norms and standards concerning customer's products and any use of the product of Infineon Technologies in customer's applications.

The data contained in this document is exclusively intended for technically trained staff. It is the responsibility of customer's technical departments to evaluate the suitability of the product for the intended application and the completeness of the product information given in this document with respect to such application.

For further information on technology, delivery terms and conditions and prices, please contact the nearest Infineon Technologies Office ([www.infineon.com](http://www.infineon.com)).

#### WARNINGS

Due to technical requirements products may contain dangerous substances. For information on the types in question please contact your nearest Infineon Technologies office.

Except as otherwise explicitly approved by Infineon Technologies in a written document signed by authorized representatives of Infineon Technologies, Infineon Technologies' products may not be used in any applications where a failure of the product or any consequences of the use thereof can reasonably be expected to result in personal injury.

Компания «Океан Электроники» предлагает заключение долгосрочных отношений при поставках импортных электронных компонентов на взаимовыгодных условиях!

Наши преимущества:

- Поставка оригинальных импортных электронных компонентов напрямую с производств Америки, Европы и Азии, а так же с крупнейших складов мира;
- Широкая линейка поставок активных и пассивных импортных электронных компонентов (более 30 млн. наименований);
- Поставка сложных, дефицитных, либо снятых с производства позиций;
- Оперативные сроки поставки под заказ (от 5 рабочих дней);
- Экспресс доставка в любую точку России;
- Помощь Конструкторского Отдела и консультации квалифицированных инженеров;
- Техническая поддержка проекта, помощь в подборе аналогов, поставка прототипов;
- Поставка электронных компонентов под контролем ВП;
- Система менеджмента качества сертифицирована по Международному стандарту ISO 9001;
- При необходимости вся продукция военного и аэрокосмического назначения проходит испытания и сертификацию в лаборатории (по согласованию с заказчиком);
- Поставка специализированных компонентов военного и аэрокосмического уровня качества (Xilinx, Altera, Analog Devices, Intersil, Interpoint, Microsemi, Actel, Aeroflex, Peregrine, VPT, Syfer, Eurofarad, Texas Instruments, MS Kennedy, Miteq, Cobham, E2V, MA-COM, Hittite, Mini-Circuits, General Dynamics и др.);

Компания «Океан Электроники» является официальным дистрибьютором и эксклюзивным представителем в России одного из крупнейших производителей разъемов военного и аэрокосмического назначения «JONHON», а так же официальным дистрибьютором и эксклюзивным представителем в России производителя высокотехнологичных и надежных решений для передачи СВЧ сигналов «FORSTAR».

## JONHON

«JONHON» (основан в 1970 г.)

Разъемы специального, военного и аэрокосмического назначения:

(Применяются в военной, авиационной, аэрокосмической, морской, железнодорожной, горно- и нефтедобывающей отраслях промышленности)

«FORSTAR» (основан в 1998 г.)

ВЧ соединители, коаксиальные кабели,  
кабельные сборки и микроволновые компоненты:

(Применяются в телекоммуникациях гражданского и специального назначения, в средствах связи, РЛС, а так же военной, авиационной и аэрокосмической отраслях промышленности).
