## 12-Bit, 170 MSPS/210 MSPS/250 MSPS, 1.8 V Analog-to-Digital Converter

## FEATURES

SNR = 69.7 dBFS at $185 \mathrm{MHz} \mathrm{A}_{\text {IN }}$ and $\mathbf{2 5 0}$ MSPS
SFDR = 87 dBc at 185 MHz Ain and 250 MSPS
-150.6 dBFS/Hz input noise at $185 \mathrm{MHz}, \mathbf{- 1} \mathrm{dBFS} \mathrm{A}_{\mathrm{IN}}$ and 250 MSPS
Total power consumption: $\mathbf{3 6 0} \mathbf{m W}$ at $\mathbf{2 5 0}$ MSPS
1.8 V supply voltages

LVDS (ANSI-644 levels) outputs
Integer 1-to-8 input clock divider ( 625 MHz maximum input)
Sample rates of up to $\mathbf{2 5 0}$ MSPS
IF sampling frequencies of up to $\mathbf{3 5 0} \mathbf{~ M H z}$
Internal ADC voltage reference
Flexible analog input range
1.4 V p-p to 2.0 V p-p (1.75 V p-p nominal)

ADC clock duty cycle stabilizer
Serial port control
Energy-saving power-down modes
User-configurable, built-in self test (BIST) capability

## APPLICATIONS

## Communications

## Diversity radio systems

Multimode digital receivers (3G)
TD-SCDMA, WiMAX, W-CDMA, CDMA2000, GSM, EDGE, LTE
I/Q demodulation systems
Smart antenna systems
General-purpose software radios
Ultrasound equipment
Broadband data applications

## GENERAL DESCRIPTION

The AD9634 is a 12-bit, analog-to-digital converter (ADC) with sampling speeds of up to 250 MSPS. The AD9634 is designed to support communications applications where low cost, small size, wide bandwidth, and versatility are desired.
The ADC core features a multistage, differential pipelined architecture with integrated output error correction logic. The ADC features wide bandwidth inputs that can support a variety of user-selectable input ranges. An integrated voltage reference eases design considerations. A duty cycle stabilizer (DCS) is provided to compensate for variations in the ADC clock duty cycle, allowing the converter to maintain excellent performance.
The ADC output data are routed directly to the external 12-bit LVDS output port.

Flexible power-down options allow significant power savings, when desired.

## Rev. 0

Information furnished by Analog Devices is believed to be accurate and reliable. However, no responsibility is assumed by Analog Devices for its use, nor for any infringements of patents or other rights of third parties that may result from its use. Specifications subject to change without notice. No license is granted by implication or otherwise under any patent or patent rights of Analog Devices. Trademarks and registered trademarks are the property of their respective owners.

Programming for setup and control is accomplished using a 3-wire, SPI-compatible serial interface.
The AD9634 is available in a 32-lead LFCSP and is specified over the industrial temperature range of $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$. This product is protected by a U.S. patent.

## PRODUCT HIGHLIGHTS

1. Integrated 12 -bit, 170 MSPS/210 MSPS/250 MSPS ADC.
2. Fast overrange and threshold detect.
3. Proprietary differential input maintains excellent SNR performance for input frequencies of up to 350 MHz .
4. 3-pin, 1.8 V SPI port for register programming and readback.
5. Pin compatibility with the AD9642, allowing a simple migration up to 14 bits, and with the AD6672.

## Timing Diagram

## AD9634

## TIMING SPECIFICATIONS

Table 5.

| Parameter | Test Conditions/Comments | Min | Typ | Max | Unit |
| :---: | :---: | :---: | :---: | :---: | :---: |
| SPI TIMING REQUIREMENTS | See Figure 58 for the SPI timing diagram |  |  |  |  |
| $t_{\text {ds }}$ | Setup time between the data and the rising edge of SCLK | 2 |  |  | ns |
| $\mathrm{t}_{\mathrm{DH}}$ | Hold time between the data and the rising edge of SCLK | 2 |  |  | ns |
| tcık | Period of the SCLK | 40 |  |  | ns |
| ts | Setup time between CSB and SCLK | 2 |  |  | ns |
| $\mathrm{t}_{\mathrm{H}}$ | Hold time between CSB and SCLK | 2 |  |  | ns |
| $\mathrm{tHIGH}^{\text {l }}$ | Minimum period that SCLK should be in a logic high state | 10 |  |  | ns |
| tow | Minimum period that SCLK should be in a logic low state | 10 |  |  | ns |
| ten_sdo | Time required for the SDIO pin to switch from an input to an output relative to the SCLK falling edge (not shown in Figure 58) | 10 |  |  | ns |
| tols_sDo | Time required for the SDIO pin to switch from an output to an input relative to the SCLK rising edge (not shown in Figure 58) | 10 |  |  | ns |

## ABSOLUTE MAXIMUM RATINGS

Table 6.

| Parameter | Rating |
| :--- | :--- |
| Electrical | -0.3 V to +2.0 V |
| AVDD to AGND | -0.3 V to +2.0 V |
| DRVDD to AGND | -0.3 V to AVDD +0.2 V |
| VIN+, VIN- to AGND | -0.3 V to AVDD +0.2 V |
| CLK,+ CLK- to AGND | -0.3 V to AVDD +0.2 V |
| VCM to AGND | -0.3 V to DRVDD +0.3 V |
| CSB to AGND | -0.3 V to DRVDD +0.3 V |
| SCLK to AGND | -0.3 V to DRVDD +0.3 V |
| SDIO to AGND | -0.3 V to DRVDD +0.3 V |
| D0 $\pm / \mathrm{D} 1 \pm$ through D10 $\pm / \mathrm{D} 11 \pm$ |  |
| $\quad$ to AGND | -0.3 V to DRVDD +0.3 V |
| DCO+/DCO- to AGND | -0.3 V to DRVDD +0.3 V |
| OR+/OR- to AGND | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ |
| Environmental |  |
| Operating Temperature Range | $150^{\circ} \mathrm{C}$ |
| $\quad$ (Ambient) |  |
| Maximum Junction Temperature |  |
| $\quad$ Under Bias | $-65^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |
| Storage Temperature Range |  |
| (Ambient) |  |

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## THERMAL CHARACTERISTICS

The exposed paddle must be soldered to the ground plane for the LFCSP package. Soldering the exposed paddle to the customer board increases the reliability of the solder joints, maximizing the thermal capability of the package.

Table 7. Thermal Resistance

| Package <br> Type | Airflow <br> Velocity <br> $(\mathbf{m} / \mathbf{s e c})$ | $\boldsymbol{\theta}_{\mathrm{JA}} \mathrm{A}^{\mathbf{1}, \mathbf{2}}$ | $\boldsymbol{\theta}_{\mathrm{Jc}}{ }^{\mathbf{1}, \mathbf{3}}$ | $\boldsymbol{\theta}_{\mathrm{JB}}{ }^{\mathbf{1 , 4}}$ | Unit |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $32-$ Lead LFCSP | 0 | 37.1 | 3.1 | 20.7 | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |
| $5 \mathrm{~mm} \times 5 \mathrm{~mm}$ | 1.0 | 32.4 |  |  | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |
| $\quad(\mathrm{CP}-32-12)$ | 2.0 | 29.1 |  |  | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |

[^2]Typical $\theta_{\text {JA }}$ is specified for a 4-layer PCB with solid ground plane. As shown in Table 7, airflow increases heat dissipation, which reduces $\theta_{J A}$. In addition, metal in direct contact with the package leads from metal traces, through holes, ground, and power planes reduces the $\theta_{\mathrm{JA}}$.

## ESD CAUTION

|  | ESD (electrostatic discharge) sensitive device. <br> Charged devices and circuit boards can discharge <br> without detection. Although this product features <br> patented or proprietary protection circuitry, damage <br> may occur on devices subjected to high energy ESD. <br> Therefore, proper ESD precautions should be taken to <br> avoid performance degradation or loss of functionality. |

## AD9634

## EQUIVALENT CIRCUITS

Figure 40. Equivalent Analog Input Circuit

Figure 41. Equivalent Clock Input Circuit

Figure 42. Equivalent LVDS Output Circuit

Figure 43. Equivalent SDIO Circuit

## THEORY OF OPERATION

The AD9634 can sample any $\mathrm{f}_{\mathrm{s}} / 2$ frequency segment from dc to 250 MHz using appropriate low-pass or band-pass filtering at the ADC inputs with little loss in ADC performance.
Programming and control of the AD9634 are accomplished using a 3-pin, SPI-compatible serial interface.

## ADC ARCHITECTURE

The AD9634 architecture consists of a front-end sample-andhold circuit, followed by a pipelined, switched-capacitor ADC. The quantized outputs from each stage are combined into a final 12-bit result in the digital correction logic. The pipelined architecture permits the first stage to operate on a new input sample and the remaining stages to operate on the preceding samples. Sampling occurs on the rising edge of the clock.
Each stage of the pipeline, excluding the last, consists of a low resolution flash ADC connected to a switched-capacitor digital-to-analog converter (DAC) and an interstage residue amplifier (MDAC). The MDAC magnifies the difference between the reconstructed DAC output and the flash input for the next stage in the pipeline. One bit of redundancy is used in each stage to facilitate digital correction of flash errors. The last stage simply consists of a flash ADC.
The input stage contains a differential sampling circuit that can be ac- or dc-coupled in differential or single-ended modes. The output staging block aligns the data, corrects errors, and passes the data to the output buffers. The output buffers are powered from a separate supply, allowing digital output noise to be separated from the analog core. During power-down, the output buffers go into a high impedance state.

## ANALOG INPUT CONSIDERATIONS

The analog input to the AD9634 is a differential switched-capacitor circuit that has been designed to attain optimum performance when processing a differential input signal.
The clock signal alternatively switches the input between sample mode and hold mode (see the configuration shown in Figure 46). When the input is switched into sample mode, the signal source must be capable of charging the sampling capacitors and settling within $1 / 2$ clock cycle.
A small resistor in series with each input can help reduce the peak transient current required from the output stage of the driving source. A shunt capacitor can be placed across the inputs to provide dynamic charging currents. This passive network creates a low-pass filter at the ADC input; therefore, the precise values are dependent on the application.

In intermediate frequency (IF) undersampling applications, reduce the shunt capacitors. In combination with the driving source impedance, the shunt capacitors limit the input bandwidth. Refer to the AN-742 Application Note, Frequency Domain Response of Switched-Capacitor ADCs; the AN-827 Application Note, A Resonant Approach to Interfacing Amplifiers to SwitchedCapacitor ADCs; and the Analog Dialogue article, "TransformerCoupled Front-End for Wideband A/D Converters" for more information on this subject.

For best dynamic performance, match the source impedances driving VIN+ and VIN- and differentially balance the inputs.

## Input Common Mode

The analog inputs of the AD9634 are not internally dc biased. In ac-coupled applications, the user must provide this bias externally. Setting the device so that $\mathrm{V}_{\mathrm{CM}}=0.5 \times$ AVDD (or 0.9 V ) is recommended for optimum performance. An on-board commonmode voltage reference is included in the design and is available from the VCM pin. Using the VCM output to set the input common mode is recommended. Optimum performance is achieved when the common-mode voltage of the analog input is set by the VCM pin voltage (typically $0.5 \times$ AVDD). The VCM pin must be decoupled to ground by a $0.1 \mu \mathrm{~F}$ capacitor, as described in the Applications Information section. Place this decoupling capacitor close to the pin to minimize the series resistance and inductance between the part and this capacitor.

## AD9634

## Differential Input Configurations

Optimum performance can be achieved when driving the AD9634 in a differential input configuration. For baseband applications, the AD8138, ADA4937-1, and ADA4930-1 differential drivers provide excellent performance and a flexible interface to the ADC.

The output common-mode voltage of the ADA4930-1 is easily set with the VCM pin of the AD9634 (see Figure 47), and the driver can be configured in a Sallen-Key filter topology to provide band limiting of the input signal.

Figure 47. Differential Input Configuration Using the ADA4930-1
For baseband applications where SNR is a key parameter, differential transformer coupling is the recommended input configuration. An example is shown in Figure 48. To bias the analog input, connect the VCM voltage to the center tap of the secondary winding of the transformer.

Figure 48. Differential Transformer-Coupled Configuration
The signal characteristics must be considered when selecting a transformer. Most RF transformers saturate at frequencies below a few megahertz. Excessive signal power can also cause core saturation, which leads to distortion.

At input frequencies in the second Nyquist zone and above, the noise performance of most amplifiers is not adequate to achieve the true SNR performance of the AD9634. For applications where SNR is a key parameter, differential double balun coupling is the recommended input configuration (see Figure 49). In this configuration, the input is ac-coupled and the VCM voltage is provided to each input through a $33 \Omega$ resistor. These resistors compensate for losses in the input baluns to provide a $50 \Omega$ impedance to the driver.

In the double balun and transformer configurations, the value of the input capacitors and resistors is dependent on the input frequency and source impedance. Based on these parameters the value of the input resistors and capacitors may need to be adjusted, or some components may need to be removed. Table 9 displays recommended values to set the RC network for different input frequency ranges. However, these values are dependent on the input signal and bandwidth and should be used only as a starting guide. Note that the values given in Table 9 are for the R1, R2, R3, C1, and C2 components shown in Figure 49.

Table 9. Example RC Network

| Frequency Range (MHz) | R1 Series $\mathbf{( \Omega )}$ | C1 Differential (pF) | R2 Series $\mathbf{( \Omega )}$ | C2 Shunt (pF) | R3 Shunt $(\mathbf{\Omega})$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
| 0 to 100 | 33 | 0 | 15 | 49.9 |  |
| 100 to 300 | 15 | 3.9 | 0 | 8.2 | 49.9 |

Figure 49. Differential Double Balun Input Configuration

WITH THE EXCEPTION OF THE 1 $\mu \mathrm{H}$ CHOKE INDUCTORS (0603LS).
2. FILTER VALUES SHOWN ARE FOR A 20MHz BANDWIDTH FILTER CENTERED AT 140MHz.
Figure 50. Differential Input Configuration Using the AD8375

An alternative to using a transformer-coupled input at frequencies in the second Nyquist zone is to use an amplifier with variable gain. The AD8375 digital variable gain amplifier (DVGA) provides good performance for driving the AD9634. Figure 50 shows an example of the AD8375 driving the AD9634 through a band-pass antialiasing filter.

## VOLTAGE REFERENCE

A stable and accurate voltage reference is built into the AD9634. The full-scale input range can be adjusted by varying the reference voltage via SPI. The input span of the ADC tracks reference voltage changes linearly.

## CLOCK INPUT CONSIDERATIONS

For optimum performance, the AD9634 sample clock inputs, CLK+ and CLK-, should be clocked with a differential signal. The signal is typically ac-coupled into the CLK+ and CLK- pins by means of a transformer or a passive component configuration. These pins are biased internally (see Figure 51) and require no external bias. If the inputs are floated, the CLK- pin is pulled low to prevent spurious clocking.

Figure 51. Equivalent Clock Input Circuit

## Clock Input Options

The AD9634 has a very flexible clock input structure. Clock input can be a CMOS, LVDS, LVPECL, or sine wave signal. Regardless of the type of signal being used, clock source jitter is of the most concern, as described in the Jitter Considerations section.
Figure 52 and Figure 53 show two preferable methods for clocking the AD9634 (at clock rates of up to 625 MHz ). A low jitter clock source is converted from a single-ended signal to a differential signal using an RF balun or RF transformer.

The RF balun configuration is recommended for clock frequencies between 125 MHz and 625 MHz , and the RF transformer is recommended for clock frequencies from 10 MHz to 200 MHz . The back-to-back Schottky diodes across the secondary windings of the transformer limit clock excursions into the AD9634 to approximately 0.8 V p-p differential. This limit helps prevent the large voltage swings of the clock from feeding through to other portions of the AD9634, while preserving the fast rise and fall times of the signal, which are critical for low jitter performance.

Figure 52. Transformer Coupled Differential Clock (Up to 200 MHz )

Figure 53. Balun-Coupled Differential Clock (Up to 625 MHz)
If a low jitter clock source is not available, another option is to ac couple a differential PECL signal to the sample clock input pins as shown in Figure 54. The AD9510, AD9511,AD9512, AD9513, AD9514, AD9515, AD9516, AD9517, AD9518, AD9520, AD9522, AD9523, AD9524, ADCLK905, ADCLK907, and ADCLK925 clock drivers offer excellent jitter performance.

## AD9634

A third option is to ac couple a differential LVDS signal to the sample clock input pins, as shown in Figure 55. The AD9510, AD9511,AD9512, AD9513, AD9514, AD9515, AD9516, AD9517, AD9518, AD9520, AD9522, AD9523, AD9524 clock drivers offer excellent jitter performance.

## Input Clock Divider

The AD9634 contains an input clock divider with the ability to divide the input clock by integer values between 1 and 8 . For divide ratios other than 1 , the DCS is enabled by default on power-up.

## Clock Duty Cycle

Typical high speed ADCs use both clock edges to generate a variety of internal timing signals and, as a result, may be sensitive to clock duty cycle. Commonly, a $\pm 5 \%$ tolerance is required on the clock duty cycle to maintain dynamic performance characteristics.
The AD9634 contains a DCS that retimes the nonsampling (falling) edge, providing an internal clock signal with a nominal $50 \%$ duty cycle. This allows the user to provide a wide range of clock input duty cycles without affecting the performance of the AD9634.

Jitter on the rising edge of the input clock is still of paramount concern and is not reduced by the duty cycle stabilizer. The duty cycle control loop does not function for clock rates less than 40 MHz nominally. The loop has a time constant associated with it that must be considered when the clock rate may change dynamically. A wait time of $1.5 \mu$ s to $5 \mu \mathrm{~s}$ is required after a dynamic clock frequency increase or decrease before the DCS loop is relocked to the input signal. During the time that the loop is not locked, the DCS loop is bypassed, and internal device timing is dependent on the duty cycle of the input clock signal. In such applications, it may be appropriate to disable the duty cycle stabilizer. In all other applications, enabling the DCS circuit is recommended to maximize ac performance.

## Jitter Considerations

High speed, high resolution ADCs are sensitive to the quality of the clock input. The degradation in SNR at a given input frequency ( fin ) due to jitter ( $\mathrm{t}_{\mathrm{t}}$ ) can be calculated by

$$
S N R_{H F}=-10 \log \left[\left(2 \pi \times f_{I N} \times t_{\text {IRMS }}\right)^{2}+10^{\left(-S N R_{L F} / 10\right)}\right]
$$

In the equation, the rms aperture jitter represents the root-mean-square of all jitter sources, which include the clock input, the analog input signal, and the ADC aperture jitter specification. IF undersampling applications are particularly sensitive to jitter, as shown in Figure 56.

Figure 56. AD9634-250 SNR vs. Input Frequency and Jitter
In cases where aperture jitter may affect the dynamic range of the AD9634, treat the clock input as an analog signal. In addition, use separate power supplies for the clock drivers and the ADC output driver to avoid modulating the clock signal with digital noise. Low jitter, crystal controlled oscillators provide the best clock sources. If the clock is generated from another type of source (by gating, dividing, or another method), it should be retimed by the original clock during the last step.

Refer to AN-501 Application Note, Aperture Uncertainty and ADC System Performance, and AN-756 Application Note, Sampled Systems and the Effects of Clock Phase Noise and Jitter, for more information about jitter performance as it relates to ADCs.

## POWER DISSIPATION AND STANDBY MODE

As shown in Figure 57, the power dissipated by the AD9634 is proportional to its sample rate. The data in Figure 57 was taken using the same operating conditions as those used for the Typical Performance Characteristics section.

Figure 57. AD9634-250 Power and Current vs. Sample Rate
By setting the internal power-down mode bits (Bits[1:0]) in the power modes register (Address 0x08) to 01, the AD9634 is placed in power-down mode. In this state, the ADC typically dissipates 5 mW . During power-down, the output drivers are placed in a high impedance state.

Low power dissipation in power-down mode is achieved by shutting down the reference, reference buffer, biasing networks, and clock. Internal capacitors are discharged when entering powerdown mode and then must be recharged when returning to normal operation. As a result, wake-up time is related to the time spent in power-down mode, and shorter power-down cycles result in proportionally shorter wake-up times.

When using the SPI port interface, the user can place the ADC in power-down mode or standby mode. Standby mode allows the user to keep the internal reference circuitry powered when faster wake-up times are required. To put the part into standby mode, set the internal power-down mode bits (Bits[1:0]) in the power modes register (Address 0x08) to 10 . See the Memory Map section and AN-877 Application Note, Interfacing to High Speed ADCs via SPI for additional details.

## DIGITAL OUTPUTS

The AD9634 output drivers can be configured for either ANSI LVDS or reduced swing LVDS using a 1.8 V DRVDD supply.
As detailed in the AN-877 Application Note, Interfacing to High Speed ADCs via SPI, the data format can be selected for offset binary, twos complement, or gray code when using the SPI control.

## Digital Output Enable Function (OEB)

The AD9634 has a flexible three-state ability for the digital output pins. The three-state mode is enabled using the SPI interface. The data outputs can be three-stated by using the output enable bar bit (Bit 4) in Register 0x14. This OEB function is not intended for rapid access to the data bus.

## Timing

The AD9634 provides latched data with a pipeline delay of 10 input sample clock cycles. Data outputs are available one propagation delay $\left(t_{\text {pD }}\right)$ after the rising edge of the clock signal.
Minimize the length of the output data lines as well as the loads placed on these lines to reduce transients within the AD9634.
These transients may degrade converter dynamic performance.
The lowest typical conversion rate of the AD9634 is 40 MSPS. At clock rates below 40 MSPS, dynamic performance can degrade.

## Data Clock Output (DCO)

The AD9634 also provides the data clock output (DCO) intended for capturing the data in an external register. Figure 2 shows timing diagram of the AD9634 output modes.

## ADC OVERRANGE (OR)

The ADC overrange indicator is asserted when an overrange is detected on the input of the ADC. The overrange condition is determined at the output of the ADC pipeline and, therefore, is subject to a latency of 10 ADC clock cycles. An overrange at the input is indicated by this bit 10 clock cycles after it occurs.

Table 10. Output Data Format

| Input (V) | VIN+ - VIN-, Input Span = 1.75 V p-p (V) | Offset Binary Output Mode | Twos Complement Mode (Default) | OR |
| :--- | :--- | :--- | :--- | :--- |
| VIN+ - VIN- | $<-0.875$ | 000000000000 | 100000000000 | 1 |
| VIN+ - VIN- | $=-0.875$ | 000000000000 | 100000000000 | 0 |
| VIN+ - VIN- | $=0$ | 100000000000 | 000000000000 | 0 |
| VIN+ - VIN- | $=+0.875$ | 111111111111 | 011111111111 | 0 |
| VIN+ - VIN- | $>+0.875$ | 111111111111 | 011111111111 | 1 |

## SERIAL PORT INTERFACE (SPI)

The AD9634 serial port interface (SPI) allows the user to configure the converter for specific functions or operations through a structured register space provided inside the ADC. The SPI offers added flexibility and customization, depending on the application. Addresses are accessed via the serial port and can be written to or read from via the port. Memory is organized into bytes that can be further divided into fields. These fields are documented in the Memory Map section. For detailed operational information, see the AN-877 Application Note, Interfacing to High Speed ADCs via SPI.

## CONFIGURATION USING THE SPI

Three pins define the SPI of this ADC: the SCLK pin, the SDIO pin, and the CSB pin (see Table 11). The SCLK (serial clock) pin is used to synchronize the read and write data presented from and to the ADC. The SDIO (serial data input/output) pin is a dual-purpose pin that allows data to be sent and read from the internal ADC memory map registers. The CSB (chip select bar) pin is an active-low control that enables or disables the read and write cycles.

Table 11. Serial Port Interface Pins

| Pin | Function |
| :--- | :--- |
| SCLK | Serial clock. The serial shift clock input, which is used to <br> synchronize serial interface reads and writes. <br> SDIO |
| Serial data input/output. A dual-purpose pin that <br> typically serves as an input or an output, depending on <br> the instruction being sent and the relative position in the <br> timing frame. <br> Chip select bar. An active-low control that gates the read <br> and write cycles. |  |

The falling edge of CSB, in conjunction with the rising edge of SCLK, determines the start of the framing. An example of the serial timing and its definitions can be found in Figure 58 and Table 5.
Other modes involving the CSB are available. The CSB can be held low indefinitely, which permanently enables the device; this is called streaming. The CSB can stall high between bytes to allow for additional external timing. When CSB is tied high, SPI functions are placed in a high impedance mode. This mode turns on any SPI pin secondary functions.
During an instruction phase, a 16-bit instruction is transmitted. Data follows the instruction phase, and its length is determined by the W0 and W1 bits.

All data is composed of 8-bit words. The first bit of each individual byte of serial data indicates whether a read or write command is issued. This allows the serial data input/output (SDIO) pin to change direction from an input to an output.
In addition to word length, the instruction phase determines whether the serial frame is a read or write operation, allowing the serial port to be used both to program the chip and to read the contents of the on-chip memory. If the instruction is a readback operation, performing a readback causes the serial data input/ output (SDIO) pin to change direction from an input to an output at the appropriate point in the serial frame.

Data can be sent in MSB-first mode or in LSB-first mode. MSBfirst mode is the default on power-up and can be changed via the SPI port configuration register. For more information about this and other features, see the AN-877 Application Note, Interfacing to High Speed ADCs via SPI.

## HARDWARE INTERFACE

The pins described in Table 11 comprise the physical interface between the user programming device and the serial port of the AD9634. The SCLK pin and the CSB pin function as inputs when using the SPI interface. The SDIO pin is bidirectional, functioning as an input during write phases and as an output during readback.
The SPI interface is flexible enough to be controlled by either FPGAs or microcontrollers. One method for SPI configuration is described in detail in the AN-812 Application Note, Microcontroller-Based Serial Port Interface (SPI) Boot Circuit.
The SPI port should not be active during periods when the full dynamic performance of the converter is required. Because the SCLK signal, the CSB signal, and the SDIO signal are typically asynchronous to the ADC clock, noise from these signals can degrade converter performance. If the on-board SPI bus is used for other devices, it may be necessary to provide buffers between this bus and the AD9634 to prevent these signals from transitioning at the converter inputs during critical sampling periods.

## SPI ACCESSIBLE FEATURES

Table 12 provides a brief description of the general features that are accessible via the SPI. These features are described in detail in AN-877 Application Note, Interfacing to High Speed ADCs via SPI.

Table 12. Features Accessible Using the SPI

| Feature Name | Description |
| :--- | :--- |
| Mode | Allows the user to set either power-down mode <br> or standby mode |
| Clock | Allows the user to access the DCS via the SPI <br> Allows the user to digitally adjust the <br> converter offset |
| Test I/O | Allows the user to set test modes to have <br> known data on output bits |
| Output Mode | Allows the user to set up outputs <br> Output Phase <br> Output Delay <br> VREF |
| Allows the user to set the output clock polarity <br> Allows the user to vary the DCO delay |  |
| Digital | Allows the user to set the reference voltage <br> Processing |
| Allows the user to enable the synchronization <br> features |  |

## AD9634

## MEMORY MAP

## READING THE MEMORY MAP REGISTER TABLE

Each row in the memory map register table has eight bit locations. The memory map is roughly divided into three sections: the chip configuration registers (Address $0 \times 00$ to Address 0x02), the transfer register (Address 0xFF), and the ADC functions registers (Address $0 \times 08$ to Address 0x25), including setup, control, and test.

The memory map register table (Table 13) documents the default hexadecimal value for each hexadecimal address shown. The Bit 7 (MSB) column is the start of the default hexadecimal value given. For example, Address $0 \times 14$, the output mode register, has a hexadecimal default value of $0 \times 01$. This means that Bit $0=1$ and the remaining bits are 0 s. This setting is the default output format value, which is twos complement. For more information on this function and others, see the AN-877 Application Note, Interfacing to High Speed ADCs via SPI. This document details the functions controlled by Register 0x00 to Register 0x25.

## Open Locations

All address and bit locations that are not included in Table 13 are not currently supported for this device. Write 0 s to unused bits of a valid address location. Writing to these locations is required only when part of an address location is open (for example, Address $0 \times 18$ ). If the entire address location is open (for example, Address 0x13), do not write to this address location.

## MEMORY MAP REGISTER TABLE

All address and bit locations that are not included in Table 13 are not currently supported for this device.
Table 13. Memory Map Registers

| Addr <br> (Hex) | Register <br> Name | Bit 7 <br> (MSB) | Bit 6 | Bit 5 | Bit 4 | Bit 3 | Bit 2 | Bit 1 | $\begin{aligned} & \text { Bit } 0 \\ & \text { (LSB) } \end{aligned}$ | Default Value (Hex) | Default <br> Notes/ <br> Comments |

## APPLICATIONS INFORMATION

## DESIGN GUIDELINES

Before starting system-level design and layout of the AD9634, it is recommended that the designer become familiar with these guidelines, which describe the special circuit connections and layout requirements needed for certain pins.

## Power and Ground Recommendations

When connecting power to the AD9634, it is recommended that two separate 1.8 V supplies be used: use one supply for analog (AVDD) and a separate supply for digital outputs (DRVDD). The designer can employ several different decoupling capacitors to cover both high and low frequencies. Locate these capacitors close to the point of entry at the PC board level and close to the pins of the part with minimal trace length.
A single PCB ground plane should be sufficient when using the AD9634. With proper decoupling and smart partitioning of the PCB analog, digital, and clock sections, optimum performance can be easily achieved.

## Exposed Paddle Thermal Heat Slug Recommendations

It is mandatory that the exposed paddle on the underside of the ADC be connected to analog ground (AGND) to achieve the best electrical and thermal performance. A continuous, exposed (no solder mask) copper plane on the PCB should be connected to the AD9634 exposed paddle, Pin 0.

The copper plane should have several vias to achieve the lowest possible resistive thermal path for heat dissipation to flow through the bottom of the PCB. These vias should be filled or plugged with nonconductive epoxy.
To maximize the coverage and adhesion between the ADC and the PCB, overlay a silkscreen to partition the continuous plane on the PCB into several uniform sections. This provides several tie points between the ADC and the PCB during the reflow process. Using one continuous plane with no partitions guarantees only one tie point between the ADC and the PCB. See the evaluation board for a PCB layout example. For detailed information about the packaging and PCB layout of chip scale packages, refer to the AN-772 Application Note, A Design and Manufacturing Guide for the Lead Frame Chip Scale Package (LFCSP).

## VCM

Decouple the VCM pin to ground with a $0.1 \mu \mathrm{~F}$ capacitor, as shown in Figure 48.

## SPI Port

The SPI port should not be active during periods when the full dynamic performance of the converter is required. Because the SCLK, CSB, and SDIO signals are typically asynchronous to the ADC clock, noise from these signals can degrade converter performance. If the on-board SPI bus is used for other devices, it may be necessary to provide buffers between this bus and the AD9634 to keep these signals from transitioning at the converter input pins during critical sampling periods.

## NOTES

# OCEAN CHIPS <br> Океан Электроники <br> Поставка электронных компонентов 

Компания «Океан Электроники» предлагает заключение долгосрочных отношений при поставках импортных электронных компонентов на взаимовыгодных условиях!

Наши преимущества:

- Поставка оригинальных импортных электронных компонентов напрямую с производств Америки, Европы и Азии, а так же с крупнейших складов мира;
- Широкая линейка поставок активных и пассивных импортных электронных компонентов (более 30 млн. наименований);
- Поставка сложных, дефицитных, либо снятых с производства позиций;
- Оперативные сроки поставки под заказ (от 5 рабочих дней);
- Экспресс доставка в любую точку России;
- Помощь Конструкторского Отдела и консультации квалифицированных инженеров;
- Техническая поддержка проекта, помощь в подборе аналогов, поставка прототипов;
- Поставка электронных компонентов под контролем ВП;
- Система менеджмента качества сертифицирована по Международному стандарту ISO 9001;
- При необходимости вся продукция военного и аэрокосмического назначения проходит испытания и сертификацию в лаборатории (по согласованию с заказчиком);
- Поставка специализированных компонентов военного и аэрокосмического уровня качества (Xilinx, Altera, Analog Devices, Intersil, Interpoint, Microsemi, Actel, Aeroflex, Peregrine, VPT, Syfer, Eurofarad, Texas Instruments, MS Kennedy, Miteq, Cobham, E2V, MA-COM, Hittite, Mini-Circuits, General Dynamics и др.);

Компания «Океан Электроники» является официальным дистрибьютором и эксклюзивным представителем в России одного из крупнейших производителей разъемов военного и аэрокосмического назначения «JONHON», а так же официальным дистрибьютором и эксклюзивным представителем в России производителя высокотехнологичных и надежных решений для передачи СВЧ сигналов «FORSTAR». JONHON
«JONHON» (основан в 1970 г.)
Разъемы специального, военного и аэрокосмического назначения:
(Применяются в военной, авиационной, аэрокосмической, морской, железнодорожной, горно- и нефтедобывающей отраслях промышленности)
«FORSTAR» (основан в 1998 г.)
ВЧ соединители, коаксиальные кабели, кабельные сборки и микроволновые компоненты:
(Применяются в телекоммуникациях гражданского и специального назначения, в средствах связи, РЛС, а так же военной, авиационной и аэрокосмической отраслях промышленности).
