Functional Description

CY62167G and CY62167GE are high-performance CMOS, low-power (MoBL®) SRAM devices with embedded ECC^[1]. Both devices are offered in single and dual chip enable options and in multiple pin configurations. The CY62167GE device includes an ERR pin that signals a single-bit error-detection and correction event during a read cycle.

To access devices with a single chip enable input, assert the chip enable (\overline{CE}) input LOW. To access dual chip enable devices, assert both chip enable inputs – \overline{CE}_1 as LOW and CE_2 as HIGH.

To perform data writes, assert the Write Enable (\overline{WE}) input LOW, and provide the data and address on the device data pins (I/O₀

through I/O₁₅) and address pins (A₀ through A₁₉) respectively. The Byte High Enable (BHE) and Byte Low Enable (BLE) inputs control byte writes and write data on the corresponding I/O lines to the memory location specified. BHE controls I/O₈ through I/O₁₅ and BLE controls I/O₀ through I/O₇.

To perform data reads, assert the Output Enable (\overline{OE}) input and provide the required address on the address lines. You can access read data on the I/O lines (I/O₀ through I/O₁₅). To perform byte accesses, assert the required byte enable signal (BHE or BLE) to read either the upper byte or the lower byte of data from the specified address location.

All I/Os (I/O₀ through I/O₁₅) are placed in a high-impedance state when the device is deselected (\overline{CE} HIGH for a single chip enable device and \overline{CE}_1 HIGH / CE_2 LOW for a dual chip enable device), or the control signals are de-asserted (\overline{OE} , BLE, BHE).

These devices have a unique Byte Power-down feature where, if both the Byte Enables (BHE and BLE) are disabled, the devices seamlessly switch to the standby mode irrespective of the state of the chip enables, thereby saving power.

On the CY62167GE devices, the detection and correction of a single-bit error in the accessed location is indicated by the assertion of the ERR output (ERR = High). See the Truth Table – CY62167G/CY62167GE on page 16 for a complete description of read and write modes.

The CY62167G and CY62167GE devices are available in a Pb-free 48-pin TSOP I package and 48-ball VFBGA packages. The logic block diagrams are on page 2.

The device in the 48-pin TSOP I package can also be configured to function as a 2M words × 8-bit device. Refer to the Pin Configurations section for details.

Notes

16. Indicates the value for the center of distribution at 3.0 V, 25 °C and not 100% tested.

19. These parameters are guaranteed by design and are not tested.
20. Full-device operation requires linear V_{CC} ramp from V_{DR} to $V_{CC(min)} \geq 100\ \mu\text{s}$ or stable at $V_{CC(min)} \geq 100\ \mu\text{s}$.
21. $\overline{BHE}.\overline{BLE}$ is the AND of both \overline{BHE} and \overline{BLE} . Deselect the chip by either disabling the chip enable signals or by disabling both \overline{BHE} and \overline{BLE} .

Notes

22. Test conditions assume signal transition time (rise/fall) of 3 ns or less, timing reference levels of 1.5 V (for $V_{CC} \geq 3$ V) and $V_{CC}/2$ (for $V_{CC} < 3$ V), and input pulse levels of 0 to 3 V (for $V_{CC} \geq 3$ V) and 0 to V_{CC} (for $V_{CC} < 3$ V). Test conditions for the read cycle use the output loading shown in Figure 6 on page 9, unless specified otherwise.
23. At any temperature and voltage condition, t_{HZOE} is less than t_{LZCE} , t_{HZBE} is less than t_{LZBE} , t_{HZOE} is less than t_{LZOE} , and t_{HZWE} is less than t_{LZWE} for any device.
24. Tested initially and after any design or process changes that may affect these parameters.
25. t_{HZOE} , t_{HZCE} , t_{HZBE} , and t_{HZWE} transitions are measured when the outputs enter a high-impedance state.
26. These parameters are guaranteed by design and are not tested.
27. The internal write time of the memory is defined by the overlap of $\overline{WE} = V_{IL}$, $\overline{CE}_1 = V_{IL}$, \overline{BHE} or \overline{BLE} or both = V_{IL} , and $CE_2 = V_{IH}$. All signals must be ACTIVE to initiate a write and any of these signals can terminate a write by going INACTIVE. The data input setup and hold timing must refer to the edge of the signal that terminates the write.
28. The minimum write cycle pulse width for Write Cycle No. 1 (\overline{WE} Controlled, \overline{OE} LOW) should be equal to the sum of t_{HZWE} and t_{SD} .

Notes

- 29. The device is continuously selected. $\overline{OE} = V_{IL}$, $\overline{CE} = V_{IL}$, \overline{BHE} or \overline{BLE} , or both = V_{IL} .
- 30. \overline{WE} is HIGH for read cycle.

Notes

31. $\overline{\text{WE}}$ is HIGH for read cycle.
32. For all dual chip enable devices, $\overline{\text{CE}}$ is the logical combination of $\overline{\text{CE}}_1$ and CE_2 . When $\overline{\text{CE}}_1$ is LOW and CE_2 is HIGH, $\overline{\text{CE}}$ is LOW; when $\overline{\text{CE}}_1$ is HIGH or CE_2 is LOW, $\overline{\text{CE}}$ is HIGH.
33. Address valid prior to or coincident with $\overline{\text{CE}}$ LOW transition.
34. The internal write time of the memory is defined by the overlap of $\overline{\text{WE}} = V_{\text{IL}}$, $\overline{\text{CE}}_1 = V_{\text{IL}}$, $\overline{\text{BHE}}$ or $\overline{\text{BLE}}$, or both = V_{IL} , and $\text{CE}_2 = V_{\text{IH}}$. All signals must be ACTIVE to initiate a write and any of these signals can terminate a write by going INACTIVE. The data input setup and hold timing must refer to the edge of the signal that terminates the write.
35. Data I/O is in the high-impedance state if $\overline{\text{CE}} = V_{\text{IH}}$, or $\overline{\text{OE}} = V_{\text{IH}}$, or $\overline{\text{BHE}}$, and/or $\overline{\text{BLE}} = V_{\text{IH}}$.
36. During this period, the I/Os are in the output state. Do not apply input signals.
37. The minimum write cycle pulse width should be equal to the sum of t_{HZWE} and t_{SD} .

Switching Waveforms (continued)

Figure 12. Write Cycle No. 2 (\overline{CE} Controlled) [38, 39, 40]

Notes

- 38. For all dual chip enable devices, \overline{CE} is the logical combination of \overline{CE}_1 and CE_2 . When \overline{CE}_1 is LOW and CE_2 is HIGH, \overline{CE} is LOW; when \overline{CE}_1 is HIGH or CE_2 is LOW, \overline{CE} is HIGH.
- 39. The internal write time of the memory is defined by the overlap of $\overline{WE} = V_{IL}$, $\overline{CE}_1 = V_{IL}$, \overline{BHE} or \overline{BLE} or both = V_{IL} , and $CE_2 = V_{IH}$. All signals must be ACTIVE to initiate a write and any of these signals can terminate a write by going INACTIVE. The data input setup and hold timing must refer to the edge of the signal that terminates the write.
- 40. Data I/O is in the high-impedance state if $\overline{CE} = V_{IH}$, or $\overline{OE} = V_{IH}$, or \overline{BHE} , and/or $\overline{BLE} = V_{IH}$.
- 41. During this period, the I/Os are in output state. Do not apply input signals.

Figure 14. Write Cycle No. 5 ($\overline{\text{WE}}$ Controlled) [42, 43, 44]

Notes

- 42. For all dual chip enable devices, $\overline{\text{CE}}$ is the logical combination of $\overline{\text{CE}}_1$ and CE_2 . When $\overline{\text{CE}}_1$ is LOW and CE_2 is HIGH, $\overline{\text{CE}}$ is LOW; when $\overline{\text{CE}}_1$ is HIGH or CE_2 is LOW, $\overline{\text{CE}}$ is HIGH.
- 43. The internal write time of the memory is defined by the overlap of $\overline{\text{WE}} = V_{\text{IL}}$, $\overline{\text{CE}}_1 = V_{\text{IL}}$, $\overline{\text{BHE}}$ or $\overline{\text{BLE}} = V_{\text{IL}}$, or both $= V_{\text{IL}}$, and $\text{CE}_2 = V_{\text{IH}}$. All signals must be ACTIVE to initiate a write and any of these signals can terminate a write by going INACTIVE. The data input setup and hold timing must refer to the edge of the signal that terminates the write.
- 44. Data I/O is in the high-impedance state if $\overline{\text{CE}} = V_{\text{IH}}$, or $\overline{\text{OE}} = V_{\text{IH}}$, or $\overline{\text{BHE}}$, and/or $\overline{\text{BLE}} = V_{\text{IH}}$.
- 45. During this period, the I/Os are in output state. Do not apply input signals.

Notes

46. This pin is available only in the 48-pin TSOP I package. Tie the \overline{BYTE} to V_{CC} to configure the device in the 1M × 16 option. The 48-pin TSOP I package can also be used as a 2M × 8 SRAM by tying the \overline{BYTE} signal to V_{SS} .

47. The 'X' (Don't care) state for the chip enables refer to the logic state (either HIGH or LOW). Intermediate voltage levels on these pins is not permitted.

48. ERR is an Output pin. If not used, this pin should be left floating.
