

## DESCRIPTION

The MP3318 is a WLED step-up converter with three current sinks and a 2.7 - 5.5V power supply input. The MP3318 uses peak-current mode to regulate the LED current set by the internal register.

The MP3318 integrates a 250mΩ, 42V MOSFET. The maximum LED voltage is up to 38V. The MP3318 is able to drive 10 LEDs in series for LCD panel applications larger than 5”.

The MP3318 supports both linear and exponential analog dimming with 11-bit, ultra-high resolution to accurately regulate the dimming current. Its auto-switching frequency function can optimize the efficiency performance. Full protection features include LED open and short protection, cycle-by-cycle current-limit protection, and thermal shutdown.

The I<sup>2</sup>C interface can set the internal register to program the MP3318 for flexible applications, such as dimming mode, LED current ramp, and protection threshold.

The MP3318 is available in a tiny WLCSP-12 (1.3mmx1.7mm) package.

## FEATURES

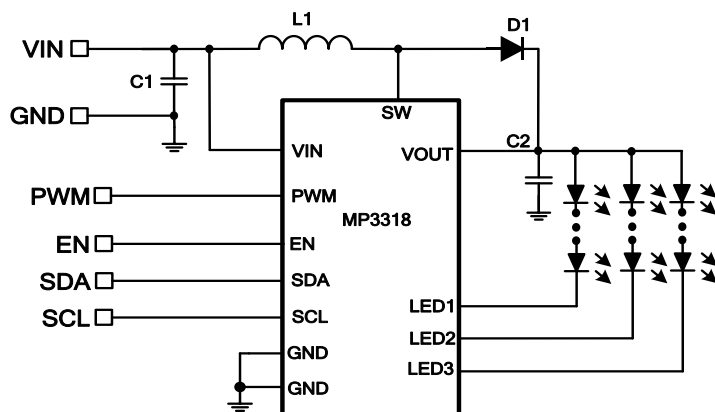

- 2.7V - 5.5V Input Voltage
- 42V, 250mΩ Internal MOSFET
- 3-Channel Current Sink, Each Channel Enable/Disable Respectively
- LED Current Up to 25mA in Backlighting Mode
- Linear or Exponential Analog Dimming
- LED Current Up to 50mA in Flash Mode
- 11-Bit Dimming Resolution
- Excellent LED Current Accuracy
- Excellent LED String Current Matching
- 500kHz/1MHz Switching Frequency with Optional -12% Shift
- Auto-Switching Frequency (250kHz, 500kHz, 1MHz)
- High-Speed I<sup>2</sup>C Interface (1.2MHz)
- Internal Soft Start to Reduce Inrush Current
- Current-Limit Protection (0.75A, 1A, 1.25A, 1.5A)
- LED Open Protection (17V, 23V, 30V, 38V)
- LED Short Protection (2V, 3V, 5V)
- Available in a WLCSP-12 (1.3mmx1.7mm) Package

## APPLICATIONS

- Smartphones
- Tablets
- GPS Receivers
- LCD Video Displays with One-Cell Li-Ion Battery

All MPS parts are lead-free, halogen-free, and adhere to the RoHS directive. For MPS green status, please visit the MPS website under Quality Assurance. “MPS” and “The Future of Analog IC Technology” are registered trademarks of Monolithic Power Systems, Inc.

## TYPICAL APPLICATION

### Efficiency vs. ILED

$V_{IN} = 3.8V$ , 3P8S, 10 $\mu$ H, DCR = 280m $\Omega$

## ORDERING INFORMATION

| Part Number* | Package                | Top Marking |

## Thermal Resistance <sup>(4)</sup>

**θ<sub>JA</sub> θ<sub>JC</sub>**  
WLCSP-12 (1.3mmx1.7mm) ... 110... 12 ... °C/W

### NOTES:

- Exceeding these ratings may damage the device.
- The maximum allowable power dissipation is a function of the maximum junction temperature T<sub>J</sub> (MAX), the junction-to-ambient thermal resistance θ<sub>JA</sub>, and the ambient temperature T<sub>A</sub>. The maximum allowable continuous power dissipation at any ambient temperature is calculated by P<sub>D</sub> (MAX) = (T<sub>J</sub> (MAX)–T<sub>A</sub>)/θ<sub>JA</sub>. Exceeding the maximum allowable power dissipation produces an excessive die temperature, causing the regulator to go into thermal shutdown. Internal thermal shutdown circuitry protects the device from permanent damage.
- The device is not guaranteed to function outside of its operating conditions.
- Measured on JESD51-7, 4-layer PCB.

## ELECTRICAL CHARACTERISTICS

V<sub>IN</sub> = 3.6V, V<sub>EN</sub> = V<sub>PWM</sub> = high, typical values are at T<sub>A</sub> = 25°C, unless otherwise noted.

## NOTES:

- 5) Matching is defined as the difference between the maximum to minimum current divided by 2x the average currents.
- 6) Guaranteed by design.
- 7) A device must internally provide a data hold time to bridge the underfined part between VIL and VIH of the falling edge of the SCLH signal. An input circuit with a threshold as low as possible for the falling edge of SCLH signal minimizes the hold time.
- 8) For the bus line load C<sub>B</sub> between 100 and 400pF the timing parameters must be increased linearly.

## BLOCK DIAGRAM

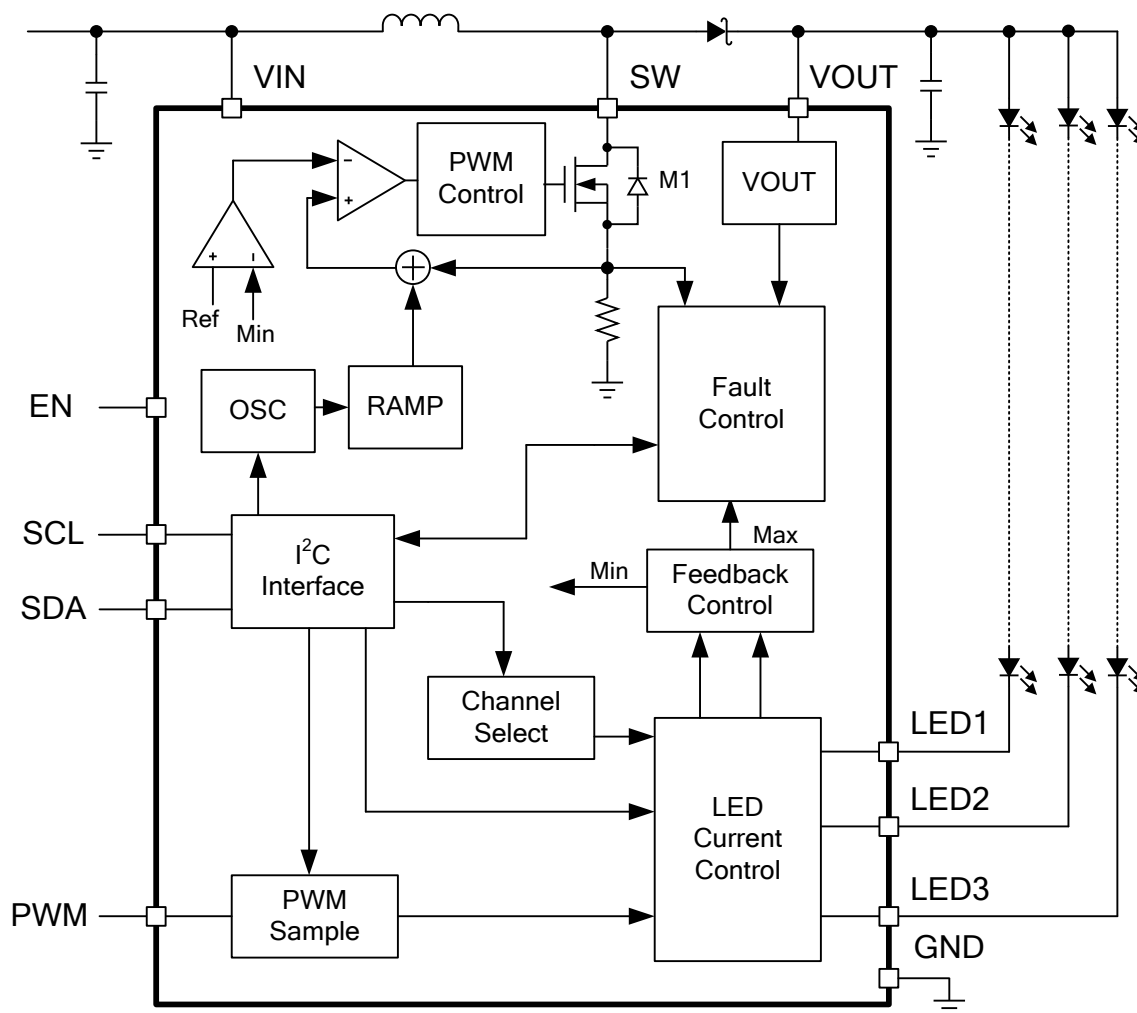

Figure 1: Functional Block Diagram

## OPERATION

The MP3318 is a step-up converter with peak-current-mode control architecture that employs three channels of current sink to drive three strings of white LED for an LCD panel. The MP3318 supports 11-bit resolution analog dimming via an internal register or external pulse-width modulation (PWM) input signal.

### Boost Converter Switching Frequency

The boost converter switching frequency can be set through the I<sup>2</sup>C. When the register bit FS = 1, the switching frequency is set to 1MHz. When the register bit FS = 0, the switching frequency is set to 500kHz. The switching frequency can be shifted down 12% by the register FS\_SHFT.

### Auto-Switching Frequency

To optimize the efficiency in different load currents, the MP3318 can select the switching frequency by comparing the auto-switching frequency low threshold (register 0x16) and auto-switching frequency high threshold (register 0x15) to 8MSBs of the brightness code (register 0x19).

The auto-switching frequency function includes three different working frequency points: 1MHz, 500kHz, and 250kHz. At the high threshold, the device switches from 1MHz to 500kHz. At the low threshold, the device switches from 500kHz to 250kHz (see Table 1).

**Table 1: Switching Frequency Auto-Select**

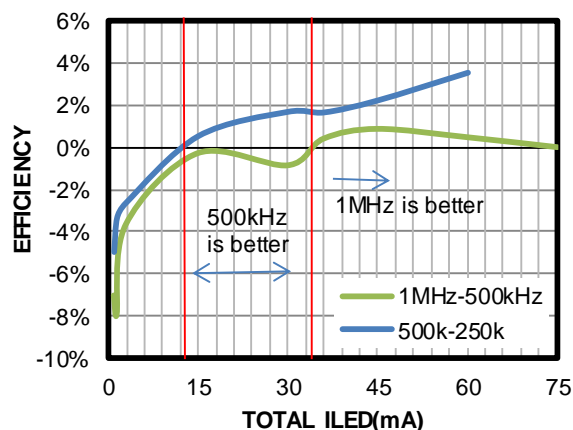

| 8MSBs of Brightness Code (Register 0x19)                                                                             | Switching Frequency |
|----------------------------------------------------------------------------------------------------------------------|---------------------|
| <auto-switching frequency low threshold (register 0x16)                                                              | 250kHz              |
| >auto-switching frequency low threshold (register 0x16)<br>< auto-switching frequency high threshold (register 0x15) | 500kHz              |
| >auto-switching frequency high threshold (register 0x15)                                                             | 1MHz                |

To disable auto-frequency, both the auto-switching frequency high threshold and low threshold must be set to zero. Once the auto-function is disabled, the MP3318 works at a fixed frequency set by the FS bit. The auto-frequency function can be enabled by setting a non-zero code for any one of the auto-switching frequency thresholds.

Note that the switching frequency -12% shift is still active when the auto-switching frequency function is enabled.

The following are test conditions for the efficiency curve in Figure 2.

- VIN = 3.8V
- 8S3P, ILED current (total) 1~75mA
- Inductor: 10μH (Wurth, 74438336100), I<sub>R</sub> = 1.2A, I<sub>SAT</sub> = 2.35A, DCR = 280mΩ

**Figure 2: ΔEfficiency between Different F<sub>SW</sub>**

**Table 2: Switching Frequency Threshold Settings**

| Switching Frequency | Total Threshold Current | Max Efficiency Improvement |
|---------------------|-------------------------|----------------------------|
| 250 - 500kHz        | <12mA                   | 5%                         |
| 500k - 1MHz         | <32mA                   | 8%                         |
| 1M - 500kHz         | >36mA                   | 1%                         |

Table 2 supplies a general recommendation for auto-switching frequency current thresholds. For the first column, 250 - 500kHz means the efficiency difference between the switching frequency is 250kHz and 500kHz.

### Minimum Inductor Selection

To optimize the boost converter control loop, the minimum inductance is limited for the MP3318, which is set by the minimum inductor L\_MIN bit. When the L\_MIN bit is set to 0, the minimum inductor is 4.7μH. When the L\_MIN bit is set to 1, the minimum inductor is 10μH.

## System Start-Up

If the input voltage is higher than the under-voltage lockout (UVLO) threshold and EN is pulled high, the MP3318 enters standby mode. In this mode, only the I<sup>2</sup>C is active and ready to communicate with the host. Meanwhile, the MP3318 monitors the topology connection and safety limits, including two checks:

- The MP3318 checks whether the VOUT connection is correct or not. A VOUT less than 1.2V cannot implement device switching and sets the FT\_UVP bit to 1.
- The MP3318 checks if the device has triggered LED open/short protection, over-current limit protection, and over-temperature protection (OTP). If all protections pass, the MP3318 starts boosting the step-up converter with an internal soft start (note that the EN bit default value is 0).

When dimming is done by the internal code only, the PWM signal can be ignored.

## Boost Converter Operation

The MP3318 uses peak-current mode to control the output voltage. At the start of each oscillator cycle, the main low-side MOSFET (LS-FET) (M1) is turned on through the control circuitry. To prevent subharmonic oscillation at duty cycles greater than 50%, a stabilizing ramp is added to the output of the current sense amplifier, and the result is fed into the positive input of the PWM generation comparator. When this voltage equals the output voltage of the error amplifier, the LS-FET is turned off. Then the inductor current flows through the free-wheeling diode, which forces the inductor current to decrease. The output voltage of the internal error amplifier is an amplified signal of the difference between the reference voltage and the feedback voltage. The converter chooses the lowest active LEDx voltage automatically to provide a bus voltage high enough to power all of the LED arrays. If the feedback voltage drops below the reference, the output of the error amplifier increases. This results in more current flowing through the MOSFET, increasing the power delivered to the output. This forms a closed loop that regulates the output voltage.

## LED String Selection

There are three LED strings for the MP3318 total. Each string has an independent enable bit. This allows for 1-string, 2-string, or 3-string applications. By default, all three strings are enabled.

## Flash Mode

Flash mode is employed in the MP3318 by setting the FL\_EN bit to 1 during backlight mode. The flash time depends on the FL\_T bit, ranging from 50 - 800ms. The flash current is set by I\_FL bit.

When flash mode is enabled, the inductor peak current limit value jumps to 3A automatically, and the switching frequency jumps to the value set by the register (0x13) FS bit. The flash current returns to backlight mode when the flash is timed out. FL\_EN is reset to 0, and the inductor peak current limit value resumes the setting value.

When a protection is triggered, flash mode ends, and the FL\_EN bit is reset.

## Dimming Control

The MP3318 supports 11-bit resolution analog dimming and features two kinds of LED current dimming curves: linear and exponential mapping.

The final LED current amplitude is set through the PWM input duty and brightness register (0x19, 0x18).

For linear analog dimming, the dimming curve and formula is shown in Equation (1):

$$I_{LED} = 40.806\mu A + 12.195\mu A \times \text{Code} \quad (1)$$

Where Code ranges from 1 - 2047. Set Code to 0 to set the LED current to 0.

For exponential analog dimming, the dimming curve and formula is shown in Equation (2):

$$I_{LED} = 51.1\mu A \times 1.003040572^{\text{Code}} \quad (2)$$

Where Code ranges from 1 - 2047. Set Code to 0 to set the LED current to 0.

Figure 2 shows the linear and exponential dimming curve for the LED current.

**Figure 3: LED Current for Each Channel with Brightness Code**

### LED Current Ramp Up/Down

The LED current ramps up or down step-by-step from one brightness code to the next when the LED current slope function is enabled by setting the SLPEN bit to 1. The ramp occurs when the LED current is changed or the EN bit is on or off.

Calculate the ramp time with Equation (3):

$$t_{\text{RAMP}} = \text{RAMP} \times (\text{Code1} - \text{Code0} - 1) \quad (3)$$

Where RAMP is the slope rate set by the TSLP register, Code0 is the original brightness point, and Code1 is the target brightness point.

### PWM Sample Frequency

Three different sample frequencies can be chosen for input PWM dimming signal in the MP3318.

- PWMSR1:0 = 00: sample frequency = 800kHz.
- PWMSR1:0 = 01: sample frequency = 4MHz (default).
- PWMSR1:0 = 1x: sample frequency = 24MHz.

Choose the PWM sample frequency based on the required dimming resolution, input dimming frequency, and efficiency (the higher the sample frequency, the higher the input consumption current). If a low-level PWM signal lasts for an extended period of time, the device can be disabled. The lower the PWM sample frequency is, the longer the PWM shutdown time is (see Table 3).

**Table 3: PWM Shutdown Time vs. Sample Frequency**

| $f_{\text{sample}}$ (Hz) | $T_{\text{PWM SD}}$ (ms) |
|--------------------------|--------------------------|
| 24M                      | 0.6                      |
| 4M                       | 3                        |
| 800k                     | 25                       |

### PWM Hysteresis

To prevent the input PWM dimming signal jitter from causing an LED flicker, the MP3318 offers selectable PWM hysteresis values.

- HYS2:0 = 000: no hysteresis.
- HYS2:0 = 001: 1 clock.
- HYS2:0 = 100: 4 clock (default).
- HYS2:0 = 110: 6 clock.

Where 1 clock =  $1/f_{\text{sample}}$ . Different sample rates achieve different clocks.

The PWM hysteresis is active only when the direction of the LED brightness changes. Once the direction of the LED brightness changes, the input PWM signal must overcome the hysteresis. Otherwise, if the LED brightness changing direction remains the same, the PWM signal hysteresis function is unused.

For example, the PWM hysteresis register is set to HYS2:0 = 100 (4 clocks).

At  $t_0$ , the input PWM duty increases, when the increment of PWM duty is smaller than four clocks, there is no change to the LED current unless the input PWM duty increments are greater than four clocks. Then the LED current responds, even at tiny increments of PWM duty.

At  $t_1$ , the PWM duty decreases, and there is no change to the LED unless the decrement of the PWM duty is greater than 4 clocks. Then, if the PWM duty continues decreasing, the LED current responds immediately by ignoring the PWM hysteresis.

### Brightness Control Mode

The LED current is controlled either by the input PWM dimming signal or internal brightness register.

Five different modes can be selected in the MP3318 described below.

### 1. Internal Register Only

When the brightness control mode bits are set to 000, the LED current is controlled by the internal brightness register only. The LED current changes only when the eight MSBs are written. Write the three LSBs first, then write the eight MSBs for the 11-bit brightness change.

In linear mapping mode, use Equation (4) and Equation (5):

$$I_{ILED0} = 40.806\mu A + 12.195\mu A \times \text{Code0} \quad (4)$$

$$I_{ILED1} = 40.806\mu A + 12.195\mu A \times \text{Code1} \quad (5)$$

In exponential mapping mode, use Equation (6) and Equation (7):

$$I_{ILED0} = 51.1\mu A \times 1.003040572^{\text{Code0}} \quad (6)$$

$$I_{ILED1} = 51.1\mu A \times 1.003040572^{\text{Code1}} \quad (7)$$

The ramp time in either mapping mode can be calculated with Equation (8):

$$t_{RAMP} = RAMP \times (\text{Code1} - \text{Code0} - 1) \quad (8)$$

### 2. Input PWM Duty Only

When the brightness control mode bits are set to 001, the LED current is controlled by the input dimming signal only. The internal brightness code is ignored. The MP3318 samples the PWM input duty and translates it into an 11-bit code to regulate the current. Choose a corresponding PWM frequency based on the PWM sample rate and resolution request.

In linear mapping mode, use Equation (9) and Equation (10):

$$I_{ILED0} = 40.806\mu A + 12.195\mu A \times 2047 \times D_{PWM0} \quad (9)$$

$$I_{ILED1} = 40.806\mu A + 12.195\mu A \times 2047 \times D_{PWM1} \quad (10)$$

In exponential mapping mode, use Equation (11) and Equation (12):

$$I_{ILED0} = 51.1\mu A \times 1.003040572^{2047 \times D_{PWM0}} \quad (12)$$

$$I_{ILED1} = 51.1\mu A \times 1.003040572^{2047 \times D_{PWM1}} \quad (13)$$

The ramp time in either mapping mode can be calculated with Equation (14):

$$t_{RAMP} = RAMP \times |2047 \times D_{PWM1} - 2047 \times D_{PWM0} - 1| \quad (14)$$

### 3. Internal Register Multiplied by the PWM Duty before Ramp

When the brightness control mode bits are set to 010, the LED current is controlled by the input PWM dimming duty multiplied by the internal brightness register. The slope step is also controlled by the PWM dimming duty multiplied by the brightness register.

In linear mode, use Equation (15) and Equation (16):

$$I_{ILED0} = 40.806\mu A + 12.195\mu A \times \text{Code0} \times D_{PWM0} \quad (15)$$

$$I_{ILED1} = 40.806\mu A + 12.195\mu A \times \text{Code1} \times D_{PWM1} \quad (16)$$

In exponential mode, use Equation (17) and Equation (18):

$$I_{ILED0} = 51.1\mu A \times 1.003040572^{\text{Code0} \times D_{PWM0}} \quad (17)$$

$$I_{ILED1} = 51.1\mu A \times 1.003040572^{\text{Code1} \times D_{PWM1}} \quad (18)$$

The ramp time in either mapping mode can be calculated with Equation (19):

$$t_{RAMP} = RAMP \times |\text{Code1} \times D_{PWM1} - \text{Code0} \times D_{PWM0} - 1| \quad (19)$$

### 4. Ramp before Internal Register Multiplied by the Input PWM Dimming Duty, LED Slope Step Controlled by Internal Register Only

When the brightness control mode bits are set to 011, the LED current is controlled by the input PWM dimming duty multiplied by the internal brightness register, and the slope step is controlled by the internal brightness register only.

In this mode, the LED current jumps immediately when the external PWM dimming duty changes. Then the LED current changes step-by-step to the new brightness register.

In linear mapping mode, the original current can be calculated with Equation (20):

$$I_{ILED0-} = 40.806\mu A + 12.195\mu A \times \text{Code0} \times D_{PWM0} \quad (20)$$

The LED current jumps immediately when the duty changes, as shown in Equation (21):

$$I_{ILED0+} = 40.806\mu A + 12.195\mu A \times \text{Code0} \times D_{PWM1} \quad (21)$$

Then, the LED current follows the code change, shown in Equation (22):

$$I_{ILED1} = 40.806\mu A + 12.195\mu A \times \text{Code1} \times D_{PWM1} \quad (22)$$

In exponential mapping mode, the original current can be calculated with Equation (23):

$$I_{ILED0-} = 51.1\mu A \times 1.003040572^{\text{Code0} \times D_{PWM0}} \quad (23)$$

The LED current jumps immediately when the duty changes, shown in Equation (24):

$$I_{ILED0+} = 51.1\mu A \times 1.003040572^{\text{Code0} \times D_{PWM1}} \quad (24)$$

Then, the LED current follows the code change, shown in Equation (25):

$$I_{ILED1} = 51.1\mu A \times 1.003040572^{\text{Code1} \times D_{PWM1}} \quad (25)$$

The ramp time in either mode can be calculated with Equation (26):

$$t_{RAMP} = RAMP \times |\text{Code1} - \text{Code0} - 1| \quad (26)$$

The original LED current can be calculated with Equation (27):

$$I_{ILED0-} = 40.806\mu A + 12.195\mu A \times (1024 \times 0.5) = 6.28\text{mA} \quad (27)$$

Then the LED current jumps immediately, as shown in Equation (28):

$$I_{ILED0+} = 40.806\mu A + 12.195\mu A \times (1024 \times 1) = 12.52\text{mA} \quad (28)$$

The LED current rises up step-by-step, shown in Equation (29):

$$I_{ILED1} = 40.806\mu A + 12.195\mu A \times (2047 \times 1) = 25\text{mA} \quad (29)$$

The ramp up time can be calculated with Equation (30):

$$t_{RAMP} = 1\text{ms/step} \times |2047 - 1024 - 1| = 1022\text{ms} \quad (30)$$

## 5. LED Current Multiplied by the Input PWM Duty, LED Slope Step Controlled by Internal Register Only

When the brightness control mode bits are set to 100, the LED current is dimmed by the input PWM dimming duty. The slope step is controlled by the internal brightness register only.

In linear mode, use Equation (31) and Equation (32):

$$I_{ILED0} = (40.806\mu A + 12.195\mu A \times \text{Code0}) \times D_{PWM0} \quad (31)$$

$$I_{ILED1} = (40.806\mu A + 12.195\mu A \times \text{Code1}) \times D_{PWM1} \quad (32)$$

In exponential mode, use Equation (33) and Equation (34):

$$I_{ILED0} = 51.1\mu A \times 1.003040572^{\text{Code0}} \times D_{PWM0} \quad (33)$$

$$I_{ILED1} = 51.1\mu A \times 1.003040572^{\text{Code1}} \times D_{PWM1} \quad (34)$$

The ramp time in either mode can be calculated with Equation (35):

$$t_{RAMP} = RAMP \times |\text{Code1} - \text{Code0} - 1| \quad (35)$$

## Cycle-by-Cycle Current Limit

To prevent the external components from exceeding a current stress rating, the MP3318 uses a cycle-by-cycle current limit protection. The limit value can be selected by the register bit CL1:0. When the internal LS-FET current exceeds the current limit threshold, the MOSFET turns off until the next clock cycle begins.

The current-limit threshold is dependent on the inductor peak current, which is decided on by the boost convert working conditions, including the inductor value (L), input voltage (V<sub>IN</sub>), output voltage (V<sub>OUT</sub>), total LED string current (I<sub>OUT</sub>), switching frequency (f<sub>SW</sub>), and boost converter efficiency (η).

For the boost converter, if Equation (36) is satisfied, then the inductor current works in continuous conduction mode (CCM). Otherwise, it works in discontinuous conduction mode (DCM).

$$\frac{I_{OUT} \times V_{OUT}}{V_{IN} \times \eta} > \frac{V_{IN}}{f_{SW} \times L} \times \left(1 - \frac{V_{IN} \times \eta}{V_{OUT}}\right) \quad (36)$$

For CCM, the peak current can be calculated with Equation (37):

$$I_{PEAK} = \frac{I_{OUT} \times V_{OUT}}{V_{IN} \times \eta} + \left[ \frac{V_{IN}}{2 \times f_{SW} \times L} \times \left(1 - \frac{V_{IN} \times \eta}{V_{OUT}}\right) \right] \quad (37)$$

For DCM, the peak current can be calculated with Equation (38):

$$I_{PEAK} = \sqrt{\frac{2 \times I_{OUT}}{f_{SW} \times L \times \eta}} \times (V_{OUT} - V_{IN} \times \eta) \quad (38)$$

Additionally, while the MP3318 works in flash mode, the current limit jumps to 3A automatically.

### Over-Current Protection (OCP)

The FT\_OCP flag is set when over-current protection (OCP) occurs. To avoid the transient over-current from setting the FT\_OCP bit, the MP3318 has an OCP counter. If the inductor current always reaches the threshold in a 128μs period, the counter increases by 1. If the OCP counter is higher than 2 every eight 128μs periods, the FT\_OCP bit is set to 1.

### Over-Voltage Protection (OVP) and Open-String Protection

When VOUT is higher than the OVP threshold, over-voltage protection (OVP) is triggered, the IC stops switching, and the FT\_OVP bit is set. When the output voltage drops low, switching resumes.

The OVP threshold is set by the internal register OVP1:0. Four different thresholds can be selected.

- OVP1:0 = 00: 17V
- OVP1:0 = 01: 23V
- OVP1:0 = 10: 30V
- OVP1:0 = 11 (default): 38V

If the LED string is open, the feedback voltage is lower than the reference voltage. Therefore, VOUT rises up and continues charging the output capacitor until VOUT reaches the protection point (V<sub>OVP</sub>), triggering OVP.

The IC also monitors the LEDx voltage. When the LEDx voltage is lower than 40mV, open LED protection is triggered. After the fault, two different actions, set by OVP\_MD1:0 through the I<sup>2</sup>C, can be triggered.

If OVP\_MD1:0 = 00, FT\_OVP is set, and FT\_OLP is set. If OVP\_MD1:0 = 01, FT\_OVP is set, FT\_OLP is set, and the string with LEDx < 40mV is marked off.

### Short LED Protection

The MP3318 monitors the LEDx pin voltage to determine if a short string has occurred. If a short string occurs, the respective LEDx pin is pulled up and can tolerate high voltage stress. If the LEDx pin voltage is higher than the short-protection threshold and last for 2ms, a short string fault is detected. The threshold is set by S\_TH1:0.

The short LED protection is programmed by the SLP\_MD1:0 as follows.

- SLP\_MD1:0 = 00: the short LED fault detection is disabled.
- SLP\_MD1:0 = 01: the short LED fault detection is enabled, and FT\_SLP is set when the fault is detected.
- SLP\_MD1:0 = 10: the short LED fault detection is enabled, FT\_SLP is set and marks off the string with the LEDx voltage higher than the threshold.

### Thermal Shutdown Protection

To prevent the IC from operating at exceedingly high temperatures, thermal shutdown is implemented by detecting the silicon die temperature. When the die temperature exceeds the upper threshold (T<sub>ST</sub>), the IC shuts down and resumes normal operation when the die temperature drops below the lower threshold. Typically, the hysteresis value is 25°C

## I<sup>2</sup>C INTERFACE REGISTER DESCRIPTION

### I<sup>2</sup>C Chip Address

The 7-bit MSB device address is 0x36. After the start condition, the I<sup>2</sup>C-compatible master sends a 7-bit address followed by an eighth read (1) or write (0) bit.

The following bit indicates the register address to or from which the data is written or read.

|   |   |   |   |   |   |   |     |
|---|---|---|---|---|---|---|-----|
| 0 | 1 | 1 | 0 | 1 | 1 | 0 | r/w |
|---|---|---|---|---|---|---|-----|

**Figure 4: I<sup>2</sup>C Compatible Device Address**

To avoid a glitch in the operation, the following registers change only when the IC EN bit (0x10, bit[0]) or the three LED channel enable bits (0x10, bit[3:1]) are set to 0.

1. Mapping mode bit (MAPMOD, 0x11, bit[7])
2. Brightness mode bits (BRTMD2:0, 0x11, bit[6:4])
3. Slope enable bit (SLPEN, 0x11, bit[3])
4. Slope time bits (TSLP2:0, 0x11, bit[2:0])
5. PWM sample rate bits (PWMSR1:0, 0x12, bit[7:6])
6. PWM polarity bit (PWM\_P, 0x12, bit[5])
7. PWM hysteresis bits (HYS2:0, 0x12, bit[4:2])
8. PWM filter bits (FILTER1:0, 0x12, bit[1:0])
9. Auto-frequency high threshold bits (FS\_AUTOH7:0, 0x15, bit[7:0])
10. Auto-frequency low threshold bits (FS\_AUTOL7:0, 0x16, bit[7:0])

## TYPICAL APPLICATION CIRCUIT

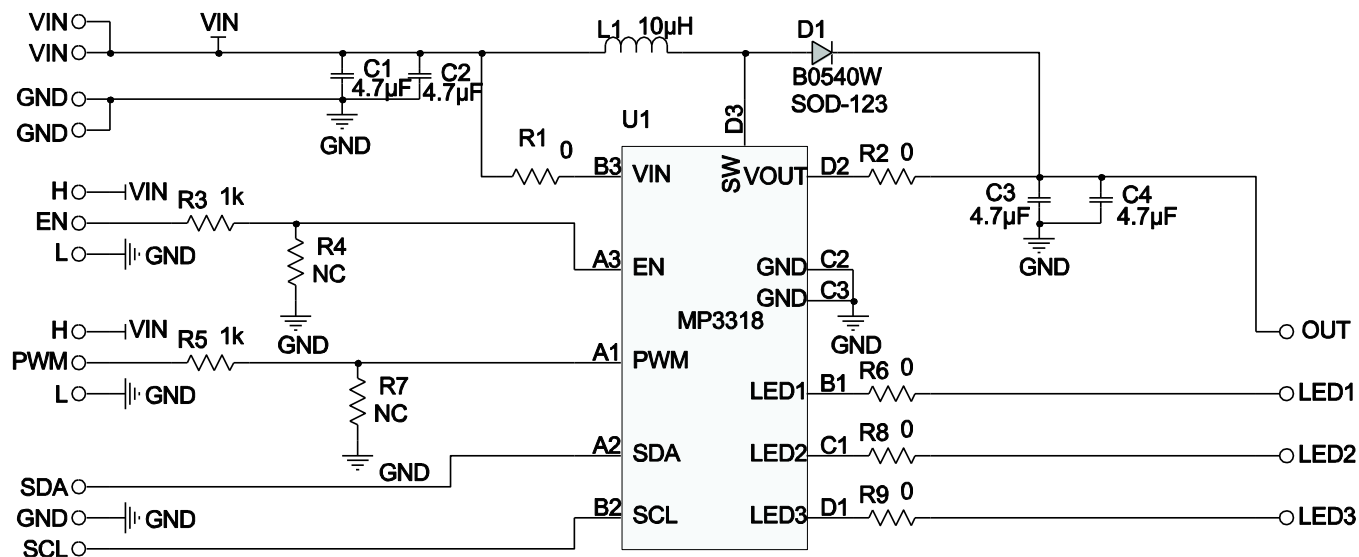

Figure 5: Typical Application for Single String 3\*7LEDs, 20mA/String

# PACKAGE INFORMATION

## WLCSP-12 (1.3mmx1.7mm)

### RECOMMENDED LAND PATTERN

### NOTE:

- 1) ALL DIMENSIONS ARE IN MILLIMETERS.
- 2) BALL COPLANARITY SHALL BE 0.05 MILLIMETER MAX.
- 3) JEDEC REFERENCE IS MO-211.
- 4) DRAWING IS NOT TO SCALE.

Компания «Океан Электроники» предлагает заключение долгосрочных отношений при поставках импортных электронных компонентов на взаимовыгодных условиях!

Наши преимущества:

- Поставка оригинальных импортных электронных компонентов напрямую с производств Америки, Европы и Азии, а так же с крупнейших складов мира;
- Широкая линейка поставок активных и пассивных импортных электронных компонентов (более 30 млн. наименований);
- Поставка сложных, дефицитных, либо снятых с производства позиций;
- Оперативные сроки поставки под заказ (от 5 рабочих дней);
- Экспресс доставка в любую точку России;
- Помощь Конструкторского Отдела и консультации квалифицированных инженеров;
- Техническая поддержка проекта, помощь в подборе аналогов, поставка прототипов;
- Поставка электронных компонентов под контролем ВП;
- Система менеджмента качества сертифицирована по Международному стандарту ISO 9001;
- При необходимости вся продукция военного и аэрокосмического назначения проходит испытания и сертификацию в лаборатории (по согласованию с заказчиком);
- Поставка специализированных компонентов военного и аэрокосмического уровня качества (Xilinx, Altera, Analog Devices, Intersil, Interpoint, Microsemi, Actel, Aeroflex, Peregrine, VPT, Syfer, Eurofarad, Texas Instruments, MS Kennedy, Miteq, Cobham, E2V, MA-COM, Hittite, Mini-Circuits, General Dynamics и др.);

Компания «Океан Электроники» является официальным дистрибьютором и эксклюзивным представителем в России одного из крупнейших производителей разъемов военного и аэрокосмического назначения «JONHON», а так же официальным дистрибьютором и эксклюзивным представителем в России производителя высокотехнологичных и надежных решений для передачи СВЧ сигналов «FORSTAR».

## JONHON

«JONHON» (основан в 1970 г.)

Разъемы специального, военного и аэрокосмического назначения:

(Применяются в военной, авиационной, аэрокосмической, морской, железнодорожной, горно- и нефтедобывающей отраслях промышленности)

«FORSTAR» (основан в 1998 г.)

ВЧ соединители, коаксиальные кабели,  
кабельные сборки и микроволновые компоненты:

(Применяются в телекоммуникациях гражданского и специального назначения, в средствах связи, РЛС, а так же военной, авиационной и аэрокосмической отраслях промышленности).
