

## Real-Time Clocks

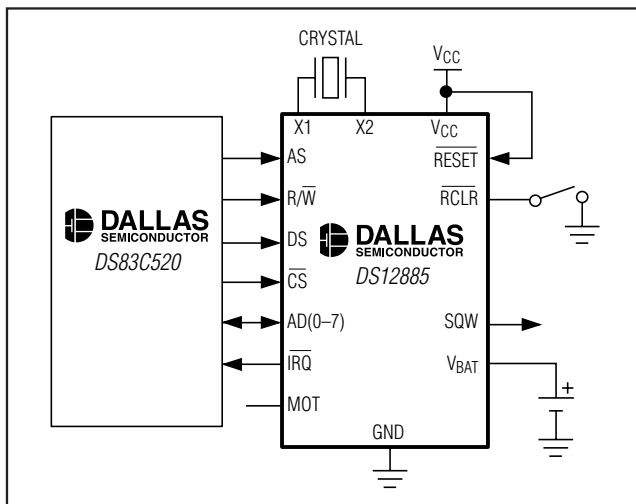

### General Description

The DS12885, DS12887, and DS12C887 real-time clocks (RTCs) are designed to be direct replacements for the DS1285 and DS1287. The devices provide a real-time clock/calendar, one time-of-day alarm, three maskable interrupts with a common interrupt output, a programmable square wave, and 114 bytes of battery-backed static RAM (113 bytes in the DS12C887 and DS12C887A). The DS12887 integrates a quartz crystal and lithium energy source into a 24-pin encapsulated DIP package. The DS12C887 adds a century byte at address 32h. For all devices, the date at the end of the month is automatically adjusted for months with fewer than 31 days, including correction for leap years. The devices also operate in either 24-hour or 12-hour format with an AM/PM indicator. A precision temperature-compensated circuit monitors the status of V<sub>CC</sub>. If a primary power failure is detected, the device automatically switches to a backup supply. A lithium coin-cell battery can be connected to the V<sub>BAT</sub> input pin on the DS12885 to maintain time and date operation when primary power is absent. The device is accessed through a multiplexed byte-wide interface, which supports both Intel and Motorola modes.

### Applications

Embedded Systems  
Utility Meters  
Security Systems  
Network Hubs, Bridges, and Routers

### Typical Operating Circuit

Pin Configurations and Ordering Information appear at end of data sheet.

### Features

- ◆ Drop-In Replacement for IBM AT Computer Clock/Calendar
- ◆ RTC Counts Seconds, Minutes, Hours, Day, Date, Month, and Year with Leap Year Compensation Through 2099
- ◆ Binary or BCD Time Representation
- ◆ 12-Hour or 24-Hour Clock with AM and PM in 12-Hour Mode
- ◆ Daylight Saving Time Option
- ◆ Selectable Intel or Motorola Bus Timing
- ◆ Interfaced with Software as 128 RAM Locations
- ◆ 14 Bytes of Clock and Control Registers
- ◆ 114 Bytes of General-Purpose, Battery-Backed RAM (113 Bytes in the DS12C887 and DS12C887A)
- ◆ RAM Clear Function (DS12885, DS12887A, and DS12C887A)
- ◆ Interrupt Output with Three Independently Maskable Interrupt Flags
- ◆ Time-of-Day Alarm Once Per Second to Once Per Day
- ◆ Periodic Rates from 122 $\mu$ s to 500ms
- ◆ End-of-Clock Update Cycle Flag
- ◆ Programmable Square-Wave Output
- ◆ Automatic Power-Fail Detect and Switch Circuitry
- ◆ Optional 28-Pin PLCC Surface Mount Package or 32-Pin TQFP (DS12885)
- ◆ Optional Encapsulated DIP (EDIP) Package with Integrated Crystal and Battery (DS12887, DS12887A, DS12C887, DS12C887A)
- ◆ Optional Industrial Temperature Range Available
- ◆ Underwriters Laboratory (UL) Recognized

DS12885/DS12887/DS12887A/DS12C887/DS12C887A

## Pin Description

PIN				NAME	FUNCTION
SO, PDIP	EDIP	PLCC	TQFP		
1	1	2	29	MOT	Motorola or Intel Bus Timing Selector. This pin selects one of two bus types. When connected to V <sub>CC</sub> , Motorola bus timing is selected. When connected to GND or left disconnected, Intel bus timing is selected. The pin has an internal pulldown resistor.
2	—	3	30	X1	Connections for Standard 32.768kHz Quartz Crystal. The internal oscillator circuitry is designed for operation with a crystal having a 6pF specified load capacitance (C <sub>L</sub> ). Pin X1 is the input to the oscillator and can optionally be connected to an external 32.768kHz oscillator. The output of the internal oscillator, pin X2, is left unconnected if an external oscillator is connected to pin X1.
3	—	4	31	X2	
4–11	4–11	5–10, 12, 14	1, 2, 3, 5, 7, 8, 9, 11	AD0–AD7	Multiplexed, Bidirectional Address/Data Bus. The addresses are presented during the first portion of the bus cycle and latched into the device by the falling edge of AS. Write data is latched by the falling edge of DS (Motorola timing) or the rising edge of R $\bar{W}$ (Intel timing). In a read cycle, the device outputs data during the latter portion of DS (DS and R $\bar{W}$ high for Motorola timing, DS low and R $\bar{W}$ high for Intel timing). The read cycle is terminated and the bus returns to a high-impedance state as DS transitions low in the case of Motorola timing or as DS transitions high in the case of Intel timing.
12, 16	12	15, 20	12, 17	GND	Ground
13	13	16	13	$\overline{CS}$	Active-Low Chip-Select Input. The chip-select signal must be asserted low for a bus cycle in the device to be accessed. $\overline{CS}$ must be kept in the active state during DS and AS for Motorola timing and during DS and R $\bar{W}$ for Intel timing. Bus cycles that take place without asserting $\overline{CS}$ will latch addresses, but no access occurs. When V <sub>CC</sub> is below V <sub>PF</sub> volts, the device inhibits access by internally disabling the $\overline{CS}$ input. This action protects the RTC data and the RAM data during power outages.
14	14	17	14	AS	Address Strobe Input. A positive-going address-strobe pulse serves to demultiplex the bus. The falling edge of AS causes the address to be latched within the device. The next rising edge that occurs on the AS bus clears the address regardless of whether $\overline{CS}$ is asserted. An address strobe must immediately precede each write or read access. If a write or read is performed with $\overline{CS}$ deasserted, another address strobe must be performed prior to a read or write access with $\overline{CS}$ asserted.
15	15	19	16	R $\bar{W}$	Read/Write Input. The R $\bar{W}$ pin has two modes of operation. When the MOT pin is connected to V <sub>CC</sub> for Motorola timing, R $\bar{W}$ is at a level that indicates whether the current cycle is a read or write. A read cycle is indicated with a high level on R $\bar{W}$ while DS is high. A write cycle is indicated when R $\bar{W}$ is low during DS. When the MOT pin is connected to GND for Intel timing, the R $\bar{W}$ signal is an active-low signal. In this mode, the R $\bar{W}$ pin operates in a similar fashion as the write-enable signal ( $\overline{WE}$ ) on generic RAMs. Data are latched on the rising edge of the signal.

# Real-Time Clocks

## Pin Description (continued)

PIN				NAME	FUNCTION
SO, PDIP	EDIP	PLCC	TQFP		
22	2, 3, 16, 20, 21, 22	1, 11, 13, 18, 26	4, 6, 10, 15, 20, 23, 25, 27, 32	N.C.	No Connection. This pin should remain unconnected. Pin 21 is $\overline{RCLR}$ for the DS12887A/DS12C887A. On the EDIP, these pins are missing by design.
17	17	21	18	DS	Data Strobe or Read Input. The DS pin has two modes of operation depending on the level of the MOT pin. When the MOT pin is connected to $V_{CC}$ , Motorola bus timing is selected. In this mode, DS is a positive pulse during the latter portion of the bus cycle and is called data strobe. During read cycles, DS signifies the time that the device is to drive the bidirectional bus. In write cycles, the trailing edge of DS causes the device to latch the written data. When the MOT pin is connected to GND, Intel bus timing is selected. DS identifies the time period when the device drives the bus with read data. In this mode, the DS pin operates in a similar fashion as the output-enable ( $\overline{OE}$ ) signal on a generic RAM.
18	18	22	19	$\overline{RESET}$	Active-Low Reset Input. The $\overline{RESET}$ pin has no effect on the clock, calendar, or RAM. On power-up, the $\overline{RESET}$ pin can be held low for a time to allow the power supply to stabilize. The amount of time that $\overline{RESET}$ is held low is dependent on the application. However, if $\overline{RESET}$ is used on power-up, the time $\overline{RESET}$ is low should exceed 200ms to ensure that the internal timer that controls the device on power-up has timed out. When $\overline{RESET}$ is low and $V_{CC}$ is above $V_{PF}$ , the following occurs: <ul style="list-style-type: none"> <li>A. Periodic interrupt-enable (PIE) bit is cleared to 0.</li> <li>B. Alarm interrupt-enable (AIE) bit is cleared to 0.</li> <li>C. Update-ended interrupt-enable (UIE) bit is cleared to 0.</li> <li>D. Periodic-interrupt flag (PF) bit is cleared to 0.</li> <li>E. Alarm-interrupt flag (AF) bit is cleared to 0.</li> <li>F. Update-ended interrupt flag (UF) bit is cleared to 0.</li> <li>G. Interrupt-request status flag (IRQF) bit is cleared to 0.</li> <li>H. <math>\overline{IRQ}</math> pin is in the high-impedance state.</li> <li>I. The device is not accessible until <math>\overline{RESET}</math> is returned high.</li> <li>J. Square-wave output-enable (SQWE) bit is cleared to 0.</li> </ul> In a typical application, $\overline{RESET}$ can be connected to $V_{CC}$ . This connection allows the device to go in and out of power fail without affecting any of the control registers.

DS12885/DS12887/DS12887A/DS12C887/DS12C887A

# Real-Time Clocks

## Pin Description (continued)

PIN				NAME	FUNCTION
SO, PDIP	EDIP	PLCC	TQFP		
19	19	23	21	$\overline{\text{IRQ}}$	Active-Low Interrupt Request Output. The $\overline{\text{IRQ}}$ pin is an active-low output of the device that can be used as an interrupt input to a processor. The $\overline{\text{IRQ}}$ output remains low as long as the status bit causing the interrupt is present and the corresponding interrupt-enable bit is set. The processor program normally reads the C register to clear the $\overline{\text{IRQ}}$ pin. The $\overline{\text{RESET}}$ pin also clears pending interrupts. When no interrupt conditions are present, the $\overline{\text{IRQ}}$ level is in the high-impedance state. Multiple interrupting devices can be connected to an $\overline{\text{IRQ}}$ bus, provided that they are all open drain. The $\overline{\text{IRQ}}$ pin is an open-drain output and requires an external pullup resistor to $V_{CC}$ .
20	—	24	22	$V_{BAT}$	Connection for a Primary Battery. (DS12885 Only.) Battery voltage must be held between the minimum and maximum limits for proper operation. If a backup supply is not supplied, $V_{BAT}$ must be grounded. Connect the battery directly to the $V_{BAT}$ pin. Diodes in series between the $V_{BAT}$ pin and the battery may prevent proper operation. UL recognized to ensure against reverse charging when used with a lithium battery.
21	21 (DS12887A/ DS12C887A)	25	24	$\overline{\text{RCLR}}$	Active-Low RAM Clear. The $\overline{\text{RCLR}}$ pin is used to clear (set to logic 1) all the general-purpose RAM, but does not affect the RAM associated with the RTC. To clear the RAM, $\overline{\text{RCLR}}$ must be forced to an input logic 0 during battery-backup mode when $V_{CC}$ is not applied. The $\overline{\text{RCLR}}$ function is designed to be used through a human interface (shorting to ground manually or by a switch) and not to be driven with external buffers. This pin is internally pulled up. Do not use an external pullup resistor on this pin.
23	23	27	26	SQW	Square-Wave Output. The SQW pin can output a signal from one of 13 taps provided by the 15 internal divider stages of the RTC. The frequency of the SQW pin can be changed by programming Register A, as shown in Table 1. The SQW signal can be turned on and off using the SQWE bit in Register B. The SQW signal is not available when $V_{CC}$ is less than $V_{PF}$ .
24	24	28	28	$V_{CC}$	DC Power Pin for Primary Power Supply. When $V_{CC}$ is applied within normal limits, the device is fully accessible and data can be written and read. When $V_{CC}$ is below $V_{PF}$ reads and writes are inhibited.

# Real-Time Clocks

## Detailed Description

The DS12885 family of RTCs provide 14 bytes of real-time clock/calendar, alarm, and control/status registers and 114 bytes (113 bytes for DS12C887 and DS12C887A) of nonvolatile, battery-backed static RAM. A time-of-day alarm, three maskable interrupts with a common interrupt output, and a programmable square-wave output are available. The devices also operate in either 24-hour or 12-hour format with an AM/PM indicator. A precision temperature-compensated circuit monitors the status of VCC. If a primary power-supply failure is detected, the devices automatically switch to a backup supply. The backup supply input supports a primary battery, such as lithium coin cell. The devices are accessed through a multiplexed address/data bus that supports Intel and Motorola modes.

## Oscillator Circuit

The DS12885 uses an external 32.768kHz crystal. The oscillator circuit does not require any external resistors or capacitors to operate. Table 1 specifies several crystal parameters for the external crystal. Figure 1 shows a functional schematic of the oscillator circuit. An enable bit in the control register controls the oscillator. Oscillator startup times are highly dependent upon crystal characteristics, PC board leakage, and layout. High ESR and excessive capacitive loads are the major contributors to long startup times. A circuit using a crystal with the recommended characteristics and proper layout usually starts within one second.

An external 32.768kHz oscillator can also drive the DS12885. In this configuration, the X1 pin is connected to the external oscillator signal and the X2 pin is left unconnected.

**Table 1. Crystal Specifications\***

PARAMETER	SYMBOL	MIN	TYP	MAX	UNITS
Nominal Frequency	$f_0$		32.768		kHz
Series Resistance	ESR			50	$k\Omega$
Load Capacitance	$C_L$		6		pF

\*The crystal, traces, and crystal input pins should be isolated from RF generating signals. Refer to Application Note 58: Crystal Considerations for Dallas Real-Time Clocks for additional specifications.

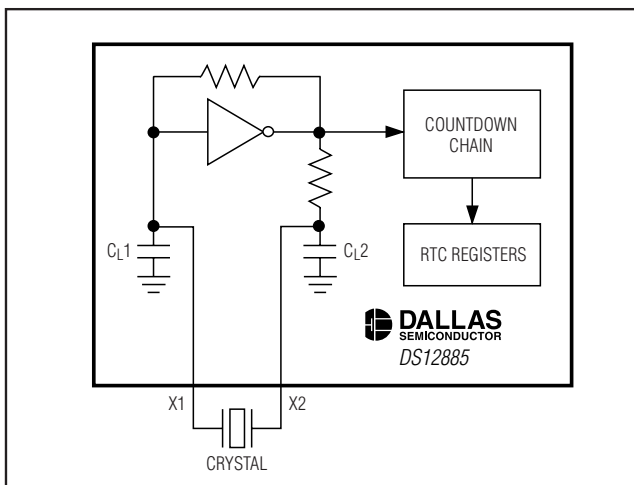

Figure 1. Oscillator Circuit Showing Internal Bias Network

# Real-Time Clocks

## Clock Accuracy

The accuracy of the clock is dependent upon the accuracy of the crystal and the accuracy of the match between the capacitive load of the oscillator circuit and the capacitive load for which the crystal was trimmed. Additional error is added by crystal frequency drift caused by temperature shifts. External circuit noise coupled into the oscillator circuit can result in the clock running fast. Figure 2 shows a typical PC board layout for isolation of the crystal and oscillator from noise. Refer to *Application Note 58: Crystal Considerations with Dallas Real-Time Clocks* for more detailed information.

### Clock Accuracy for DS12887, DS12887A, DS12C887, DS12C887A Only

The encapsulated DIP modules are trimmed at the factory to an accuracy of  $\pm 1$  minute per month at  $+25^{\circ}\text{C}$ .

## Power-Down/Power-Up Considerations

The real-time clock continues to operate, and the RAM, time, calendar, and alarm memory locations remain nonvolatile regardless of the  $V_{CC}$  input level.  $V_{BAT}$  must remain within the minimum and maximum limits when  $V_{CC}$  is not applied. When  $V_{CC}$  is applied and exceeds  $V_{PF}$  (power-fail trip point), the device becomes accessible after  $t_{REC}$ —if the oscillator is running and the oscillator countdown chain is not in reset (Register A). This time allows the system to stabilize after power is applied. If the oscillator is not enabled, the oscillator-enable bit is enabled on power-up, and the device becomes immediately accessible.

## Time, Calendar, and Alarm Locations

The time and calendar information is obtained by reading the appropriate register bytes. The time, calendar, and alarm are set or initialized by writing the appropriate register bytes. Invalid time or date entries result in undefined operation. The contents of the 10 time, calendar, and alarm bytes can be either binary or binary-coded decimal (BCD) format.

The day-of-week register increments at midnight, incrementing from 1 through 7. The day-of-week register is used by the daylight saving function, so the value 1 is defined as Sunday. The date at the end of the month is

Figure 2. Layout Example

automatically adjusted for months with fewer than 31 days, including correction for leap years.

Before writing the internal time, calendar, and alarm registers, the SET bit in Register B should be written to logic 1 to prevent updates from occurring while access is being attempted. In addition to writing the 10 time, calendar, and alarm registers in a selected format (binary or BCD), the data mode bit (DM) of Register B must be set to the appropriate logic level. All 10 time, calendar, and alarm bytes must use the same data mode. The SET bit in Register B should be cleared after the data mode bit has been written to allow the RTC to update the time and calendar bytes. Once initialized, the RTC makes all updates in the selected mode. The data mode cannot be changed without reinitializing the 10 data bytes. Tables 2A and 2B show the BCD and binary formats of the time, calendar, and alarm locations.

The 24-12 bit cannot be changed without reinitializing the hour locations. When the 12-hour format is selected, the higher-order bit of the hours byte represents PM when it is logic 1. The time, calendar, and alarm bytes are always accessible because they are double-buffered. Once per second the seven bytes are advanced by one second and checked for an alarm condition.

If a read of the time and calendar data occurs during an update, a problem exists where seconds, minutes, hours, etc., may not correlate. The probability of reading incorrect time and calendar data is low. Several methods of avoiding any possible incorrect time and calendar reads are covered later in this text.

## Real-Time Clocks

The three alarm bytes can be used in two ways. First, when the alarm time is written in the appropriate hours, minutes, and seconds alarm locations, the alarm interrupt is initiated at the specified time each day, if the alarm-enable bit is high. In this mode, the “0” bits in the alarm registers and the corresponding time registers must always be written to 0 (Table 2A and 2B). Writing the 0 bits in the alarm and/or time registers to 1 can result in undefined operation.

The second use condition is to insert a “don’t care” state in one or more of the three alarm bytes. The don’t-care code is any hexadecimal value from C0 to FF. The two most significant bits of each byte set the don’t-care

condition when at logic 1. An alarm is generated each hour when the don’t-care bits are set in the hours byte. Similarly, an alarm is generated every minute with don’t-care codes in the hours and minute alarm bytes. The don’t-care codes in all three alarm bytes create an interrupt every second.

All 128 bytes can be directly written or read, except for the following:

- 1) Registers C and D are read-only.
- 2) Bit 7 of register A is read-only.
- 3) The MSB of the seconds byte is read-only.

**Table 2A. Time, Calendar, and Alarm Data Modes—BCD Mode (DM = 0)**

ADDRESS	BIT 7	BIT 6	BIT 5	BIT 4	BIT 3	BIT 2	BIT 1	BIT 0	FUNCTION	RANGE
00H	0	10 Seconds			Seconds				Seconds	00–59
01H	0	10 Seconds			Seconds				Seconds Alarm	00–59
02H	0	10 Minutes			Minutes				Minutes	00–59
03H	0	10 Minutes			Minutes				Minutes Alarm	00–59
04H	AM/PM	0	0	10 Hours	Hours				Hours	1–12 +AM/PM 00–23
	0		10 Hours							
05H	AM/PM	0	0	10 Hours	Hours				Hours Alarm	1–12 +AM/PM 00–23
	0		10 Hours							
06H	0	0	0	0	0	Day			Day	01–07
07H	0	0	10 Date		Date				Date	01–31
08H	0	0	0	10 Months	Month				Month	01–12
09H	10 Years				Year				Year	00–99
0AH	UIP	DV2	DV1	DV0	RS3	RS2	RS1	RS0	Control	—

0CH	IRQF	PF	AF	UF	0	0	0	0	Control	—
0DH	VRT	0	0	0	0	0	0	0	Control	—
0EH–31H	X	X	X	X	X	X	X	X	RAM	—
32H	10 Century				Century				Century*	00–99
33H–7FH	X	X	X	X	X	X	X	X	RAM	—

X = Read/Write Bit.

\*DS12C887, DS12C887A only. General-purpose RAM on DS12885, DS12887, and DS12887A.

**Note:** Unless otherwise specified, the state of the registers is not defined when power is first applied. Except for the seconds register, 0 bits in the time and date registers can be written to 1, but may be modified when the clock updates. 0 bits should always be written to 0 except for alarm mask bits.

# Real-Time Clocks

## Control Registers

The real-time clocks have four control registers that are accessible at all times, even during the update cycle.

### Control Register A

MSB				LSB			
BIT 7	BIT 6	BIT 5	BIT 4	BIT 3	BIT 2	BIT 1	BIT 0
UIP	DV2	DV1	DV0	RS3	RS2	RS1	RS0

**Bit 7: Update-In-Progress (UIP).** This bit is a status flag that can be monitored. When the UIP bit is a 1, the update transfer occurs soon. When UIP is a 0, the update transfer does not occur for at least 244 $\mu$ s. The time, calendar, and alarm information in RAM is fully available for access when the UIP bit is 0. The UIP bit is read-only and is not affected by  $\overline{\text{RESET}}$ . Writing the SET bit in Register B to a 1 inhibits any update transfer and clears the UIP status bit.

**Bits 6, 5, and 4: DV2, DV1, DV0.** These three bits are used to turn the oscillator on or off and to reset the countdown chain. A pattern of 010 is the only combination of bits that turn the oscillator on and allow the RTC to keep time. A pattern of 11x enables the oscillator but holds the countdown chain in reset. The next update occurs at 500ms after a pattern of 010 is written to DV0, DV1, and DV2.

**Bits 3 to 0: Rate Selector (RS3, RS2, RS1, RS0).** These four rate-selection bits select one of the 13 taps on the 15-stage divider or disable the divider output. The tap selected can be used to generate an output square wave (SQW pin) and/or a periodic interrupt. The user can do one of the following:

- 1) Enable the interrupt with the PIE bit;
- 2) Enable the SQW output pin with the SQWE bit;
- 3) Enable both at the same time and the same rate; or
- 4) Enable neither.

Table 3 lists the periodic interrupt rates and the square-wave frequencies that can be chosen with the RS bits. These four read/write bits are not affected by  $\overline{\text{RESET}}$ .

## Real-Time Clocks

### Control Register C

MSB				LSB			
BIT 7	BIT 6	BIT 5	BIT 4	BIT 3	BIT 2	BIT 1	BIT 0
IRQF	PF	AF	UF	0	0	0	0

**Bit 7: Interrupt Request Flag (IRQF).** This bit is set to 1 when any of the following are true:

PF = PIE = 1

AF = AIE = 1

UF = UIE = 1

Any time the IRQF bit is 1, the  $\overline{\text{IRQ}}$  pin is driven low. This bit can be cleared by reading Register C or with a  $\overline{\text{RESET}}$ .

**Bit 6: Periodic Interrupt Flag (PF).** This bit is read-only and is set to 1 when an edge is detected on the selected tap of the divider chain. The RS3 through RS0 bits establish the periodic rate. PF is set to 1 independent of the state of the PIE bit. When both PF and PIE are 1s, the  $\overline{\text{IRQ}}$  signal is active and sets the IRQF bit. This bit can be cleared by reading Register C or with a  $\overline{\text{RESET}}$ .

**Bit 5: Alarm Interrupt Flag (AF).** A 1 in the AF bit indicates that the current time has matched the alarm time. If the AIE bit is also 1, the  $\overline{\text{IRQ}}$  pin goes low and a 1 appears in the IRQF bit. This bit can be cleared by reading Register C or with a  $\overline{\text{RESET}}$ .

**Bit 5: Update-Ended Interrupt Flag (UF).** This bit is set after each update cycle. When the UIE bit is set to 1, the 1 in UF causes the IRQF bit to be a 1, which asserts the  $\overline{\text{IRQ}}$  pin. This bit can be cleared by reading Register C or with a  $\overline{\text{RESET}}$ .

**Bits 3 to 0: Unused.** These bits are unused in Register C. These bits always read 0 and cannot be written.

### Control Register D

MSB				LSB			
BIT 7	BIT 6	BIT 5	BIT 4	BIT 3	BIT 2	BIT 1	BIT 0
VRT	0	0	0	0	0	0	0

**Bit 7: Valid RAM and Time (VRT).** This bit indicates the condition of the battery connected to the  $V_{\text{BAT}}$  pin. This bit is not writeable and should always be 1 when read. If a 0 is ever present, an exhausted internal lithium energy source is indicated and both the contents of

the RTC data and RAM data are questionable. This bit is unaffected by  $\overline{\text{RESET}}$ .

**Bits 6 to 0: Unused.** The remaining bits of Register D are not usable. They cannot be written and they always read 0.

## Real-Time Clocks

### Century Register (DS12C887/DS12C887A Only)

The century register at location 32h is a BCD register designed to automatically load the BCD value 20 as the year register changes from 99 to 00. The MSB of this register is not affected when the load of 20 occurs, and remains at the value written by the user.

### Nonvolatile RAM (NV RAM)

The general-purpose NV RAM bytes are not dedicated to any special function within the device. They can be used by the processor program as battery-backed memory and are fully available during the update cycle.

### Interrupts

The RTC family includes three separate, fully automatic sources of interrupt for a processor. The alarm interrupt can be programmed to occur at rates from once per second to once per day. The periodic interrupt can be selected for rates from 500ms to 122 $\mu$ s. The update-ended interrupt can be used to indicate to the program that an update cycle is complete. Each of these independent interrupt conditions is described in greater detail in other sections of this text.

The processor program can select which interrupts, if any, are to be used. Three bits in Register B enable the interrupts. Writing a logic 1 to an interrupt-enable bit permits that interrupt to be initiated when the event occurs. A 0 in an interrupt-enable bit prohibits the  $\overline{\text{IRQ}}$  pin from being asserted from that interrupt condition. If an interrupt flag is already set when an interrupt is enabled,  $\overline{\text{IRQ}}$  is immediately set at an active level, although the interrupt initiating the event may have occurred earlier. As a result, there are cases where the program should clear such earlier initiated interrupts before first enabling new interrupts.

When an interrupt event occurs, the relating flag bit is set to logic 1 in Register C. These flag bits are set independent of the state of the corresponding enable bit in Register B. The flag bit can be used in a polling mode without enabling the corresponding enable bits. The interrupt flag bit is a status bit that software can interrogate as necessary. When a flag is set, an indication is given to software that an interrupt event has occurred since the flag bit was last read; however, care should be taken when using the flag bits as they are cleared each time Register C is read. Double latching is included with Register C so that bits that are set remain stable throughout the read cycle. All bits that are set (high) are cleared when read, and new interrupts that are pending during the read cycle are held until after the cycle is completed. One, two, or three bits can be set

when reading Register C. Each used flag bit should be examined when Register C is read to ensure that no interrupts are lost.

The second flag bit method is used with fully enabled interrupts. When an interrupt flag bit is set and the corresponding interrupt-enable bit is also set, the  $\overline{\text{IRQ}}$  pin is asserted low.  $\overline{\text{IRQ}}$  is asserted as long as at least one of the three interrupt sources has its flag and enable bits set. The IRQF bit in Register C is a 1 whenever the  $\overline{\text{IRQ}}$  pin is driven low. Determination that the RTC initiated an interrupt is accomplished by reading Register C. A logic 1 in bit 7 (IRQF bit) indicates that one or more interrupts have been initiated by the device. The act of reading Register C clears all active flag bits and the IRQF bit.

### Oscillator Control Bits

When the DS12887, DS12887A, DS12C887, and DS12C887A are shipped from the factory, the internal oscillator is turned off. This prevents the lithium energy cell from being used until the device is installed in a system.

A pattern of 010 in bits 4 to 6 of Register A turns the oscillator on and enables the countdown chain. A pattern of 11x (DV2 = 1, DV1 = 1, DV0 = X) turns the oscillator on, but holds the countdown chain of the oscillator in reset. All other combinations of bits 4 to 6 keep the oscillator off.

### Square-Wave Output Selection

Thirteen of the 15 divider taps are made available to a 1-of-16 multiplexer, as shown in the functional diagram. The square-wave and periodic-interrupt generators share the output of the multiplexer. The RS0–RS3 bits in Register A establish the output frequency of the multiplexer (see Table 1). Once the frequency is selected, the output of the SQW pin can be turned on and off under program control with the square-wave enable bit, SQWE.

### Periodic Interrupt Selection

The periodic interrupt causes the  $\overline{\text{IRQ}}$  pin to go to an active state from once every 500ms to once every 122 $\mu$ s. This function is separate from the alarm interrupt, which can be output from once per second to once per day. The periodic interrupt rate is selected using the same Register A bits that select the square-wave frequency (Table 1). Changing the Register A bits affects the square-wave frequency and the periodic-interrupt output. However, each function has a separate enable bit in Register B. The SQWE bit controls the square-wave output. Similarly, the PIE bit in Register B enables the periodic interrupt. The periodic interrupt can be used with software counters to measure inputs, create output intervals, or await the next needed software function.

## Real-Time Clocks

**Table 3. Periodic Interrupt Rate and Square-Wave Output Frequency**

SELECT BITS REGISTER A				t <sub>PI</sub> PERIODIC INTERRUPT RATE	SQW OUTPUT FREQUENCY
RS3	RS2	RS1	RS0		
0	0	0	0	None	None
0	0	0	1	3.90625ms	256Hz
0	0	1	0	7.8125ms	128Hz
0	0	1	1	122.070μs	8.192kHz
0	1	0	0	244.141μs	4.096kHz
0	1	0	1	488.281μs	2.048kHz
0	1	1	0	976.5625μs	1.024kHz
0	1	1	1	1.953125ms	512Hz
1	0	0	0	3.90625ms	256Hz
1	0	0	1	7.8125ms	128Hz
1	0	1	0	15.625ms	64Hz
1	0	1	1	31.25ms	32Hz
1	1	0	0	62.5ms	16Hz
1	1	0	1	125ms	8Hz
1	1	1	0	250ms	4Hz
1	1	1	1	500ms	2Hz

### Update Cycle

The device executes an update cycle once per second regardless of the SET bit in Register B. When the SET bit in Register B is set to 1, the user copy of the double-buffered time, calendar, and alarm bytes is frozen and does not update as the time increments. However, the time countdown chain continues to update the internal copy of the buffer. This feature allows time to maintain accuracy independent of reading or writing the time, calendar, and alarm buffers, and also guarantees that time and calendar information is consistent. The update cycle also compares each alarm byte with the corre-

sponding time byte and issues an alarm if a match or if a don't-care code is present in all three positions.

There are three methods that can handle RTC access that avoid any possibility of accessing inconsistent time and calendar data. The first method uses the update-ended interrupt. If enabled, an interrupt occurs after every update cycle that indicates over 999ms is available to read valid time and date information. If this interrupt is used, the IRQF bit in Register C should be cleared before leaving the interrupt routine.

A second method uses the update-in-progress bit (UIP) in Register A to determine if the update cycle is in progress. The UIP bit pulses once per second. After the UIP bit goes high, the update transfer occurs 244μs later. If a low is read on the UIP bit, the user has at least 244μs before the time/calendar data is changed. Therefore, the user should avoid interrupt service routines that would cause the time needed to read valid time/calendar data to exceed 244μs.

The third method uses a periodic interrupt to determine if an update cycle is in progress. The UIP bit in Register A is set high between the setting of the PF bit in Register C (Figure 3). Periodic interrupts that occur at a rate greater than t<sub>BUC</sub> allow valid time and date information to be reached at each occurrence of the periodic interrupt. The reads should be complete within one (t<sub>PI</sub> + t<sub>BUC</sub>) to ensure that data is not read during the update cycle.

### Handling, PC Board Layout, and Assembly

The EDIP module can be successfully processed through conventional wave-soldering techniques so long as temperature exposure to the lithium energy source does not exceed +85°C. Post-solder cleaning with water-washing techniques is acceptable, provided that ultrasonic vibration is not used. Such cleaning can damage the crystal.

## Chip Information

PROCESS: CMOS

SUBSTRATE CONNECTED TO GROUND

Компания «Океан Электроники» предлагает заключение долгосрочных отношений при поставках импортных электронных компонентов на взаимовыгодных условиях!

Наши преимущества:

- Поставка оригинальных импортных электронных компонентов напрямую с производств Америки, Европы и Азии, а так же с крупнейших складов мира;
- Широкая линейка поставок активных и пассивных импортных электронных компонентов (более 30 млн. наименований);
- Поставка сложных, дефицитных, либо снятых с производства позиций;
- Оперативные сроки поставки под заказ (от 5 рабочих дней);
- Экспресс доставка в любую точку России;
- Помощь Конструкторского Отдела и консультации квалифицированных инженеров;
- Техническая поддержка проекта, помощь в подборе аналогов, поставка прототипов;
- Поставка электронных компонентов под контролем ВП;
- Система менеджмента качества сертифицирована по Международному стандарту ISO 9001;
- При необходимости вся продукция военного и аэрокосмического назначения проходит испытания и сертификацию в лаборатории (по согласованию с заказчиком);
- Поставка специализированных компонентов военного и аэрокосмического уровня качества (Xilinx, Altera, Analog Devices, Intersil, Interpoint, Microsemi, Actel, Aeroflex, Peregrine, VPT, Syfer, Eurofarad, Texas Instruments, MS Kennedy, Miteq, Cobham, E2V, MA-COM, Hittite, Mini-Circuits, General Dynamics и др.);

Компания «Океан Электроники» является официальным дистрибьютором и эксклюзивным представителем в России одного из крупнейших производителей разъемов военного и аэрокосмического назначения «JONHON», а так же официальным дистрибьютором и эксклюзивным представителем в России производителя высокотехнологичных и надежных решений для передачи СВЧ сигналов «FORSTAR».

## JONHON

«JONHON» (основан в 1970 г.)

Разъемы специального, военного и аэрокосмического назначения:

(Применяются в военной, авиационной, аэрокосмической, морской, железнодорожной, горно- и нефтедобывающей отраслях промышленности)

«FORSTAR» (основан в 1998 г.)

ВЧ соединители, коаксиальные кабели, кабельные сборки и микроволновые компоненты:

(Применяются в телекоммуникациях гражданского и специального назначения, в средствах связи, РЛС, а так же военной, авиационной и аэрокосмической отраслях промышленности).
