## Block Diagram

## Function

The LV5212VH consists of 1) an 8-stage D-type flip-flop and 2) an 8-stage D-type flip-flop connected to the output of 1). When data is supplied to the serial data input (SDATAIN) and the clock pulse is supplied to the clock input (SCK), the serial data input signal is input to the internal shift register and the data already in the shift register shifted sequentially when the clock changes from low to high.

The serial output (SOUT) is used to connect multiple LV5212VH to expand the number of bits and is connected to the SDATAIN of the next stage. (Cascade connection supported.)

For parallel output, when the output control enable input (XEN) is low, the latch input (LATCH) changes from low to high and the clock pulse input changes from low to high, the serial data input signal is output to LED01, and the output is shifted sequentially. For parallel outputs (LED2 to LED8), the signals whose polarities inverted from those of the serial data input (SDATAIN) are output.

When the EN input is high, outputs LED01 through LED01 all turn off.

When the reset input is low, outputs LED01 through LED8 and SOUT outputs all turn off. The power must be turned on after checking that the reset input is low.
